In the movement of heavy machinery there are many difficulties to overcome. I remember a punch and shears we ordered that when crated weighed 13½ tons. The only trouble in handling this piece was from the railroad-car to the river-boat, a distance of not over a hundred feet, but it took 70 men 10 days to get it off the car and on the boat. The extra freight for excess weight on the machine was horrible, as I remember it, about 400% of the regular ton weight. We unloaded this easily with our derrick, but it would have been impossible to have taken it up to some of the mines in the hills. In this respect manufacturers should carefully consider the sectionalizing of machinery for mule or other transport into localities requiring it.

Returning to the extension of our trade with foreign houses, it seems to me there are certain rules that must be followed if we are to keep this trade.

(1.) The catalogue, which is the first introduction to the new customer, should be compiled carefully and accurately for the country in which it is to be used and in the

language of that country. It should fairly and in full detail describe the articles to be sold, giving the weight, net and crated, for export shipment; if for large machinery, the weight and size of the largest piece should be stated. Prices and all charges, terms of payment and delivery, should be fairly set forth. If discounts from these prices are given and these must be written for, this should be stated clearly.

(2.) Correspondence: The first letter of inquiry should have personal attention given to it and the endeavor made to establish a personal relationship. If orders follow this, personal interest should be extended and continued in the hope of making a confirmed customer; especial attention should be accorded to complaints.

(3.) Packing: The directions for this should be fully given and carried out.

(4.) Bills-of-lading and consular invoices should be carefully prepared, filled out, and forwarded promptly with invoices and packing-lists. Also in the case of machinery, instructions and blue-prints should accompany the letters. Of course, all this must be made out in the language of the customer.

(5.) A request should be sent to the customer with every shipment asking him to write on receipt of goods, stating the condition of the goods on arrival and whether perfectly satisfactory. Also asking him for suggestions as to any means he might propose in which better service could have been given, this for reference in future shipments. A regular form-card could be sent for this purpose, and it should be checked on return and filed for future shipments.

By such a system I believe we could establish a foreign trade based on such honesty of goods and service that other nations would find it hard to take it from us. It is not altogether a question of price. We must learn to do business in the way of our customers and to gain their confidence. We cannot know them without living among them and understanding their conditions. And only by knowing them and establishing a common bond of dependence, can we hope to keep their trade. And above all, our Government must encourage and protect young men going into foreign countries and working there to advance themselves and American trade.

Belt-Conveyors

For moving material supplied in a continuous stream, a belt conveyor is well adapted. The capacity of a narrow belt is surprisingly high in consequence of the speed at which it may be run. Reginald Trautschold, writing in the *Engineering Magazine*, gives the most economic speed for various materials handled by belt-conveyors. Coke is best conveyed at 250 ft. per minute. Coarse broken stone and lump coal should also have low speeds, about 275 ft. per minute. Fine coal, however, is best handled at the high speed of 400 ft. per minute. Sand or gravel and ordinary crushed stone, are conveyed most economically at 375 ft. per minute. A belt-

conveyor 1 ft. wide can handle nearly 90 tons of sand per hour, while one 3 ft. wide has a capacity of 800 tons per hour, or nine times as great, in each case run at a speed of 375 ft. per minute. These figures apply only when conditions are working perfectly. The power requirement of belt-conveyors is low. A 30-in. belt, when working at most economic speed, can handle 270 tons of fine coal per hour, elevating 20 ft., and distributing the coal by an automatic tripper over a 50-ft. storage-bunker, at a requirement of $13\frac{1}{2}$ hp., of which $5\frac{1}{2}$ hp. would be needed for the horizontal travel, $5\frac{1}{2}$ for elevating the load, and $2\frac{1}{2}$ for the tripper, the conveyor being equipped with grease-lubricated idlers. If ball-bearing idlers are used, the power consumed would be $11\frac{3}{4}$ hp., the reduction of $1\frac{3}{4}$ hp. being principally the saving in friction on the horizontal travel.

The best grade of rubber is none too good for a conveyor, as its large capacity makes initial cost secondary in importance to that of wearing quality. The labor charge for inspecting and repairing conveyors is generally taken at $1\frac{1}{2}$ c. per hour per inch of width. The cost for grease and incidental supplies varies directly with the horse-power consumed, and averages $\frac{1}{2}$ c. per hp. per hour. Depreciation of a belt comes from hardening of the rubber, and is more apt to follow idleness than careful use. Ordinarily, an annual depreciation charge of 25% on the belt covers the wear and tear. The net operating cost on an 18-in. belt-conveyor, 500 ft. long, handling 85,000 tons of fine coal at a rate of 85 tons per hour for 1000 hours per year, was less than 2c. per ton. This conveyor elevated the coal 30 ft. and distributed it over a bunker 100 ft. long by means of an automatic traveling tripper, power being furnished at 2c. per hp.-hour. The speed was 400 ft. per minute; the power was 14 hp. (11 hp. if roller-bearings are used); the initial cost of equipment was \$3720; depreciation was charged at \$710 per year; annual fixed charges were \$316; labor cost \$270 per year; and power cost \$280 per year.

When a large quantity of material has to be handled at a rapid rate in a limited space, and the cost for power is not so important as the initial investment, flight-conveyors may be used. While their speed is slow, the load per foot is high. The best advisable speed is 100 to 200 ft. per minute. A horizontal flight-conveyor, 8 by 18 by 16 in., 150 ft. long, handling 150,000 tons of fine coal in 600 operating hours, the power costing 2c. per hp.-hour, would have a net operating cost of 0.8c. per ton. The advisable speed would be 200 ft. per minute; the capacity 260 tons per hour; the power required would be $31\frac{1}{2}$ hp., costing \$378 per year using shoe-flights, or 28 $\frac{1}{2}$ hp., costing \$342 per year using roller-flights; the initial cost of equipment would be \$655 with shoe-flights or \$880 with roller-flights.

Screw conveyors have comparatively a limited capacity and a high consumption of power. They are particularly well liked for handling cement. Though cheap in first cost, the depreciation is rapid; the screw revolving in the load receives destructive abrasive action. The economic speed is governed by the diameter of the screw,

NEDERLAND: ONE OF THE BOULDER COUNTY TUNGSTEN TOWNS.

Tungsten in the Boulder District, Colorado

By E. H. Leslie

In the year 1870, Sam. P. Conger, prospector and pioneer, in going over the hills of Boulder county found a heavy, dark mineral which occurred as float. The true nature of this mineral was a mystery to Conger and others, to whom it became known as 'heavy iron,' 'hematite,' 'black iron,' or 'barren silver.' It was considered to be of little commercial importance until many years later when a prospector, W. H. Wanamaker, a partner of Conger's, returned from a prospecting trip in the Dragoon mountains of Arizona, where he came across similar mineral. This he ascertained to be ferberite, the tungstate of iron. Wanamaker and Conger kept the matter secret, making every effort in the meantime to secure possession of some of the placer tungsten and vein deposits of Boulder county. In August, 1900, Conger secured a lease on the property which is now known as the Conger mines in the Nederland district, and by the end of that year extracted about 40 tons of high-grade ore. In 1901 the production amounted to 65 tons, which was marketed at \$2.25 per unit. In 1902 there was a decided slump, making operating conditions unfavorable. From that time until about a year ago, the mining of tungsten ore in Boulder county was spasmodic and of comparatively little importance, although interest in the district was kept alive and considerable prospecting was done. Within the last year a decided revival in interest in tungsten has taken place by reason of the abnormal market conditions for tool steel and other uses to which it has been found so well adapted.

The principal part of the tungsten district of Boulder county is the south-eastern quarter. The latest geologic maps show that the tungsten mining area has a general north-east and south-west trend, dipping down into Gilpin county on the south, where some important discoveries have been made. The principal towns in the district are Nederland, Cardinal, Phoenixville, Rollinsville, Sugarloaf, and Magnolia.

Most of the mines are found in the granite, gneissoid granite, and the more granitic parts of the gneiss. A number of the properties are situated close to the contact of gneiss and granite; in some places the workings are almost entirely within the gneiss. In the Nederland-Beaver Creek area, a number of veins follow the dikes of coarse and fine pegmatite, but the relationship is due to structure rather than to any common genesis. The fissuring now occupied by the veins, which were long subsequent to the formation of the pegmatite dikes, followed the lines of least resistance, which in several places coincided with the dikes. Other veins are associated with a fine-grained intrusive biotite-granite which forms dikes and irregular masses, such as that at the Clyde mine, a mile north-east of Nederland. In some cases the vein leaves the dike entirely and passes out into the neighboring formation, usually at a sharp angle with the dikes. In the north-western area, the long line of mines and prospects roughly parallel to middle Boulder and Boulder creeks, near Castle Rock, is closely associated with a narrow but rather continuous dike of

fine-grained granite. In places the entire width of the dike is occupied by the vein. There is no regular system of veins, but in the Nederland and Beaver Creek area a great many strike north-east and south-west. Few have a strike west of north. The average strike of 11 well-defined veins in the western part of the Nederland-Beaver Creek area is north 32° east. The angle of dip of the veins is generally steep, often approaching the vertical and rarely falling as low as 45° .

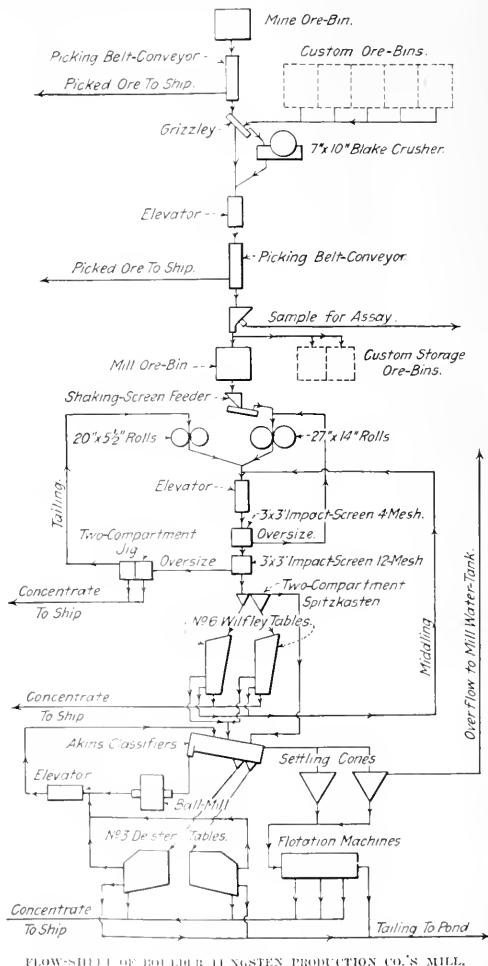

For further details of the economic geology of these tungsten deposits I suggest a study of R. D. George's monograph entitled 'The Main Tungsten Area of Boulder County, Colorado.'

In Boulder canyon the mines are generally worked through adits by over-hand stoping methods, with raises and open stopes requiring little timber. The veins as a rule dip at a steep angle of from 75° to 90° and the strike is generally north-east and south-west. Some of the larger operators have power at the mines for drilling, but single and double-jacking methods are responsible for a great part of the output. In some instances miners are working from the outcrops by open-cut methods. In the vicinity of Nederlands the mines are generally worked through shafts, the deepest of which, at the Conger mine, is down 1160 ft. Others in the district are from 200 to 400 ft. deep. The water problem is comparatively insignificant. The average ore contains from 1.5 to 2.5%, although ore has been found in quantity averaging as much as 35% tungstic oxide (WO_3).

Milling practice closely follows standard wet concentration methods, although these have been amplified to meet more fully the requirements of the ferberite. In early work on this ore it was found that a good deal of the tungsten-content was contained in the slime, and as such, in the ordinary milling methods, the greater part of the loss occurred in this division of classification. To meet this loss, it has been found that rolls or mills of the Chilean type are better adapted for crushing than stamps, due to their making less slime and a better product for jigs and tables. It may be said that excellent work is being done at the Wolf Tongue plant, which is an old re-modeled stamp-mill. As supplementary to regular milling there have been added 'rag-mills' or stationary canvas tables, which have increased the recovery materially. The mills are generally of from 15 to 25 tons' capacity daily, although on another class of ore and with the same equipment they would undoubtedly treat a much greater tonnage. It has been found that it is impossible to crowd the mill in treating tungsten ore, without a decided reduction in the extraction. When I say that the mills are making an average recovery of from 89 to 91% of the tungsten content of the ore treated, I am quoting several of the superintendents and operators of the larger mills. A good deal of the ore treated is that from small operators and lessees. The concentrate averages from 60 to 65% WO_3 .

The Clark mill of the Boulder Tungsten Production Co., situated just east of the big Nederland dam in what is known as Stevens Camp, is representative of the most

modern practice for the treatment of the local ferberite ore. This plant, which was built at a cost of \$25,000, commenced operation at the beginning of 1916, and it was said that its entire cost was repaid by the first month's profit. The mill was designed by Randall P. Akins of the Colorado Iron Works Co., which company supplied all equipment and superintended its construction. It was designed as a 30-ton mill, and was working

FLOW-SHEET OF BOULDER TUNGSTEN PRODUCTION CO.'S MILL.

90 days after the contract was signed. The accompanying flow-sheet shows the process employed. The final residue is passed over stationary canvas-tables or a rag-mill not shown in the flow-sheet. The flotation machines shown in the flow-sheet were not installed at the time of my visit, but plans were being prepared for a thorough investigation of the adaptability of flotation as a supplement to milling, with special reference to the slime product, which is at present being treated on tables and in the rag plant.

The ore treated varies from 0.5 to 2%, giving an extraction of about 90%. The mill is driven by three electric motors, supplied with current by the Colorado Central Power Co.; about 50 hp. is required for the entire plant.

The following is an outline of the treatment at a few of the other mills in the district:

At the Wolf Tongue, which is one of the oldest here, machinery consists of a jaw-crusher, stamps, jigs, Wilfley and Card tables, Monnell slime-tables, classifiers, and stationary canvas-tables or rag-plant. The flow-sheet has been undergoing many changes lately, but the work done is said to be highly satisfactory.

The Lucky Two Tungsten Co. has been treating tungsten ores since 1910. Its equipment consists of two Denver quartz mills, two pairs of 12 by 20-in. rolls, jigs, Wilfley tables, Monnell slime-tables, and rag-plant. The mill is treating 25 tons daily.

At the Duncan mill, at the Black Prince property, there is an 8 by 12-in. Denver crusher, Denver quartz mill, 12 by 20-in. McFarland rolls, Richards' jig, two Wilfley tables, two Monnell slime-tables, a rag-plant and accessories.

The mill of the Tungsten Mines Co., between Nederland and Rollinsville, on Beaver creek, has been in operation since 1910, and has similar equipment to that mentioned above. The Red Sign mine of the Primos company will erect shortly a mill following general practice.

far show that there it is probable that flotation will find a place in the treatment of ferberite ores.

The trip from Denver to the tungsten district, a distance of 60 miles, is generally made by automobile. That there is a mining boom in Boulder county is advertised on the street corners of Denver by display placards on automobiles, in hotel lobbies, by groups of mining men discussing the strength or weakness of the tungsten market, and in offices of the machinery manufacturers, who are being called on to meet an abnormal market for all

STREET SCENE AT NEDERLAND.

MAP SHOWING SITUATION OF TUNGSTEN FIELD.

The Ross and Foley is another of the representative mills of the district.

Some experimental work is being done at the Wolf Tongue mill of the Vaseo company to determine the applicability of flotation to the Boulder County ores. It is also proposed, as stated, to experiment with this process at the Clark mill. While tests have not progressed to a point that will warrant a definite statement, results so

far show that there it is probable that flotation will find a place in the treatment of ferberite ores. It is not at all unusual to hear of a mill being constructed in two or three months and paying for itself in an equal length of time. The road to Boulder, on an early Sunday morning especially, is crowded with machines, trucks, and wagons laden with sight-seers, miners, equipment, and all that goes into the making of the mushroom growth of a boom community. At Boulder, where a stop is usually made before entering the canyon, the streets are filled with a heterogeneous collection of people and conveyances. Beyond and through the canyon one continuous stream of motor-cars pours its burden through the gulches and over the precipitous mountain road into Nederland. The trip is punctuated with trucks and cars that have gone over the embankments and others which have been unable to make the grades. Nederland, like Oatman, Arizona, is a dry camp and as a result, the movies and soft-drink emporiums are the sole diversions, while a greater amount of miners' and lessees' earnings are going into drill-steel, dynamite, and savings accounts. The streets, or more properly street, is congested with people and traffic, and the landscape presents the appearance of a national guard encampment with the numerous tents, commissaries, bunk-houses, pine lumber, and unpainted buildings, which spring up almost over night. At the time of my visit, during May, the town had grown from a population of about 500 six months ago to one of about 4000 people.

VALUE of copper, lead, silver, and zinc produced in the Central States during 1915 was \$121,283,262, an increase of 120% compared with that for 1914, this being principally in zinc and copper.

Atmospheric Humidity and Its Measurement

By Kenneth G. Smith

*The large number of deaths from heat in the Eastern States recently has drawn attention to the excessive humidity of the atmosphere, which was registered on one day as 70%. Humidity in mine air is also an important problem. According to the law of partial pressures, commonly known as Dalton's law, two gases at the same temperature do not interfere with each other's pressures when mixed, provided there is no chemical action. Each one exerts the same pressure that it would at the given temperature if the other were not present. The total pressure is the sum of the pressures of the two gases. Experiment shows that this law holds good for a mixture of gas and vapor such as water-vapor and air. Taking water-vapor and air as an example, if P_a is the air-pressure and P_o the vapor-pressure, then $P_a + P_o = P_t$ = total pressure of vapor and air. If the vapor is saturated, the temperature of the mixture is definitely fixed at the saturation temperature corresponding to the pressure P_t . If the temperature is higher than the saturation temperature at the given pressure, the vapor is superheated. Water-vapor in the atmosphere is superheated except on damp, foggy days, when the water-vapor is saturated, or as we say, the air is saturated with moisture.

The weight of a cubic foot of superheated vapor is less than the weight of a cubic foot of saturated vapor. If m_1 is the weight of a cubic foot of saturated vapor, and m_2 = weight of a cubic foot of superheated vapor at the same temperature, then the ratio $\frac{m_2}{m_1}$ expressed in per cent is called the humidity of the air containing the vapor; that is, it is the ratio of the moisture actually contained in the air to that which the air could contain at that temperature if saturated.

If a mixture of air and superheated vapor is cooled at constant pressure (say atmospheric pressure), it will finally reach a point where the vapor becomes saturated instead of superheated, and further cooling results in condensation. The temperature at which condensation begins is called the dew-point. This is simply the saturation temperature for the given pressure. The gas law $PV = \text{constant}$, which we may assume holds good for low-vapor pressures, gives us the means of calculating the ratio $\frac{m_2}{m_1}$ already referred to as the humidity.

Let P_1V_1 represent the condition of saturated vapor at the given temperature, and P_2V_2 its actual condition at this temperature—that is, in its superheated state. Then

$$P_2V_2 = P_1V_1 \text{ and } \frac{P_2}{P_1} = \frac{V_1}{V_2}$$

If the vapor is cooled at a constant pressure P_1 down to the saturation temperature—that is, to the dew-point—

then since P_2 is unchanged the ratio $\frac{P_2}{P_1} = \frac{V_1}{V_2}$ still holds good; now substituting for the volumes per cubic foot, their reciprocals, the weights per cubic foot, $\frac{P_2}{P_1} = \frac{m_2}{m_1}$.

Hence, the humidity in per cent is equal to the ratio of the pressure, corresponding to the dew-point, to the saturation pressure, corresponding to the temperature of the mixture. An example will make this method of measuring humidity clear. Suppose that air has a temperature of 70°, and the dew-point is found to be 50°. What is the humidity and weight of vapor per cubic foot? From a table of vapor-pressure we find that at 55° the saturation pressure is 0.436 in. of mercury. At 75° the saturation pressure is 0.8735 in. of mercury.

The humidity is then $\frac{0.436}{0.8735} = 50\%$, nearly. If the air were saturated at 75°, it would contain 9.36 grains of moisture per cubic foot. Hence, at 50% saturation it contains $9.36 \times 0.5 = 4.68$ grains per cubic foot.

To measure moisture in this way would be difficult under other than laboratory conditions, and for that reason another method, using a wet and a dry-bulb thermometer, has been adopted. The dry-bulb thermometer is simply an ordinary Fahrenheit thermometer. The wet-bulb instrument is exactly the same except that it has a piece of muslin or other porous material wrapped around the bulb and saturated with water. When both are exposed to the air, the wet-bulb thermometer immediately falls to a lower temperature than the other, owing to the fact that the evaporation of the moisture in the cloth requires heat. The drier the air the more the evaporation and the greater the drop in temperature. From the difference in temperature between the wet and dry-bulb thermometers the humidity may be calculated. In practice it is not calculated, but read directly from a table or curve.

One might naturally ask the reason for the fixed temperature to which the wet-bulb thermometer drops. This temperature is known as the temperature of adiabatic saturation, and is fixed for any dry-bulb temperature and percentage of humidity. To understand this statement, imagine three thermometers placed in a body of air to which moisture is to be added without exchange of heat with any source outside of the air and water. The first thermometer is arranged to show the dew-point and reads the lowest. The second or dry-bulb thermometer shows the dry-bulb temperature or, as we call it, the temperature of the air. The third thermometer shows a temperature between the dry-bulb temperature and the dew-point. Take, for example, air as 70° and 33% saturated. Then the conditions are as follows: dry-bulb temperature, 70°; dew-point, 39°; wet-bulb temperature, 54°.

If now a fine spray of water having a temperature higher than 39° is introduced, the air absorbs moisture, with the result that the dry-bulb temperature drops at once, the dew point temperature rises and the wet-bulb temperature remains stationary. The reason is that the total heat of the air is constant. The heat required to evaporate the moisture is rendered latent, and the sen-

*Abstract from *Compressed Air Magazine*, originally published in *Iowa Engineer* of Iowa State College.

sible heat as shown by the dry-bulb thermometer becomes less, but the sum of latent and sensible heat is constant. If moisture continues to be added, the dew-point temperature continues to rise, the dry-bulb temperature continues to fall until all three are stationary at the wet-bulb temperature, when the air is saturated. The total heat of the air is the same as it was before the moisture was added, but it contains more latent and less sensible heat. On the total heat the wet-bulb temperature depends, and therefore it is fixed for any temperature and percentage of humidity, because the total heat of the air in the given condition is fixed.

In the example given the percentage of humidity may be calculated if we know the dry and wet-bulb temperatures. These are as given, dry-bulb 70°, wet-bulb 54°. The temperature of adiabatic saturation is 54°, and at

this temperature the air contains 62.14 grains per pound when saturated. The total heat of the mixture equals the heat of the air plus the heat of the moisture, or

$$0.2375 \times 54 + \frac{1084.7 \times 62.14}{7000} = 22.44 \text{ B.t.u.}$$

Since the total heat of the air is constant during the change, the total heat at 70° equals the total heat at 54°, or

$$0.2375 \times 70 + (1084.7) + 0.48 \times 16 \times X = 22.44$$

X = Grains of moisture in air at 70°.

0.48 = Specific heat of the vapor.

Solving for X , we have $X = 37.2$ grains per pound of air.

Since saturated air at 70° contains 110.01 grains per pound, the humidity is $\frac{37.2}{110.01} = 33\%$.

Jig Concentration in Joplin District, Missouri

By Clarence A. Wright

*The most common type of jig used in this district is known as the Cooley, which is similar in principle to the Harz. It is of the fixed-sieve type, the water being forced up and down through the screens or grates by the action of a plunger placed in an adjacent compartment. The number and size of the compartments for each jig depend on the size and character of the ore treated.

In general, a system of 'roughing' and 'cleaning' is followed in which the feed is given a preliminary cleaning that eliminates the greater proportion of waste material on one or two rougher-jigs and the enriched product, which will assay from 14 to 18% zinc, is cleaned on a cleaner-jig for the final treatment, bring-

ing the zinc tenor up to 55 to 60%. The 'chats' or included mineral particles from both the rougher and the cleaner-jigs, which together will assay 4 to 8% zinc, are re-crushed, and either returned to the rougher-jig feed or treated separately over a chat-jig. The tailing from the rougher-jig is dewatered by means of a trommel with $1\frac{1}{2}$ to 2 mm. openings, over the outside of which the tailing passes as the trommel slowly revolves. The undersize from this dewater-screen flows to settling-tanks and the oversize to the tailing elevator as waste. The overflow from the tailing-end of the cleaner-jig and other jigs, if used, also passes to the settling-tanks for subsequent treatment.

The rougher-jigs usually consist of 5 to 6 cells with a screening or grate-area of 30 by 42 in. to 36 by 48 in. The speed of the shaft connecting the plunger and eccentrics varies from 90 to 120 r.p.m., with the length of the stroke of the plungers ranging from $\frac{5}{8}$ to $1\frac{1}{4}$ in. The cleaner-jigs have 6 to 7 cells with a grate-area somewhat smaller than that of the rougher-jig. The speed of the shaft connecting the eccentrics and plungers is from

*Abstract from *Joplin Globe*.

NEW TYPE OF JIGS IN TAILING-MILL AT CHITWOOD, MISSOURI.

160 to 200 strokes per minute, with lengths of stroke ranging from $\frac{3}{8}$ to $\frac{3}{4}$ in. The chat-jigs, which are not commonly used, are smaller and usually consist of 4 to 5 cells, and are operated at a higher speed and shorter stroke.

The material fed to the first cell of the jig is, as a rule, not graded or classified. A bed, 5 to 6 in. deep, is formed, and as a result of the pulsating action of the water the lighter gangue material, such as flint, settles on the surface, the heavier free grains of lead and zinc working to the bottom. The downward suction-stroke causes the finer grains of minerals to continue through the screen or grate-openings into the hutch of each compartment. The strength of the suction-stroke is increased by leaving the gates of the hutch partly open. The accumulation in the hutch is known as 'smitten,' and is further treated on the cleaner-jig. The bed products of the first two or three cells are also drawn-off and pass, together with the hutch-product, to the cleaner-jig. The chats or included mineral particles, usually from the last hutch and the last two or three beds, are drawn-off and re-ground before further treatment.

It has been found from various tests that a few minor changes in the flow-sheet or treatment of the ore would seem feasible to effect more efficient jigging and to make a greater saving possible.

The feed to the rougher-jig, which in most cases is ungraded material, consists of both coarse and fine material. In the treatment of a sheet-ground ore we find that 3.25% of the feed to the rougher-jig consisted of material finer than 200-mesh, with a zinc-content of 5.77%, which represented 1.72% of the total zinc in the feed. Also the screen analyses of the tailing before it was dewatered, show that the assay-value of the material finer than 200-mesh was 4.50% zinc, indicating that a small recovery was made on this size material as it passed over the jig. The percentage of material finer than 200-mesh in the tailings was 3.62, which represented 32.26% of the total zinc in the tailing. Screen analyses of the dewatered tailings showed that there was still 1.09% of the material finer than 200-mesh contained in the tailings, with an assay value of 4.20% zinc, which was discarded.

It is reasonable to believe from the above figures alone that it would be advisable to de-slime at the head of the rougher-jig. However, the importance of de-sliming is more strongly emphasized by the fact that the dewatering screens as used at the end of the jigs in this district are, as a rule, not very efficient, which means a loss of fine mineral in the jig-tailing. To show this more fully the efficiency of the dewatering screen at the end of the rougher-jig was determined. It should be stated that the object of the dewatering screen is not to eliminate the water from the tailing, but to collect as much of the fine as possible from the tailing overflowing at the end of the jig for further treatment on tables. The dewatering screen had 1.5-mm. openings; the screening efficiency was as follows:

Screen product, size of opening	Screen feed %	Screen over- size, %
Over 1.5 mm.	80.1	87.5
Through 1.5 mm.	19.9	12.5

Weight of undersize in the oversize = $80.1 \times 12.5 \div 87.5 = 11.44$. Screening efficiency = $19.9 - 11.44$ or $8.46 \div 19.9 = 42.51\%$.

Another important point is that the greater the quantity of slime in the feed the more value or fine mineral particles will be forced over the jig by the flow of the top water. This fact is especially true as the quantity of water added to the cells of the jig increases the top water of each succeeding cell. Better work can also be obtained from the jig by having clear top water, which is another reason, when the material is not sized, why the feed to the rougher-jig should be de-slimed, although this would not mean the elimination of the dewatering screen at the end of the rougher-jig.

Copper Production for Six Months

The following compilation shows properties in North and South America whose production for the first half of 1916 has been reported, in pounds:

	1916	1915	Increase %
Anaconda	164,500,000	112,200,000	46
Phelps, Dodge & Co.	85,000,000	65,000,000	30
Utah Copper	84,949,000	67,216,000	26

*No production. †Estimated. ‡Decrease.

In the first half of 1915 the Greene-Canaanea plants were closed owing to disturbances in Mexico. The Chile Copper Co. did not start its mill until May, 1915, so that the copper produced to end of the following June was only a few thousand pounds. The Inspiration mill did not get under way until June 2, 1915.—*Boston News Bureau.*

More than half the world's production of copper in normal times is used for the manufacture of electrical equipment.

Cyaniding Clayey Ore at the Buckhorn Mine, Nevada

By Paul R. Cook

*The ore deposit of the Buckhorn Mines Co., Buckhorn, Nevada, is peculiar as it occurs as a shallow kaolinized mass of material with basalt walls, having apparently no direct connection with any of the usual gold-bearing rocks. The ore generally contains 16% water of hydration, and the cyaniding of this hydrous clayey material offered unusual difficulties when compared with the typical gold-quartz ores of Nevada. The orebody was thoroughly developed. Then the mill was built according to the latest cyanide practice, embodying changes necessitated by the peculiar nature of this ore; but on starting the mill, the ore proved more difficult to treat than had been anticipated.

Considerable trouble was experienced in mining the sticky ore and getting it to the treatment plant. The next problem was to get the ore out of the mill-bin and to crush it. The bin was an ordinary circular steel type, with natural earth bottom and side gate. This ore would not run from the bin. The mill was designed to treat 300 tons per day, but even with one man in the ore-bin and two at the crusher, it was impossible to get more than 150 tons through in 24 hours. In crushing, the large kaolin lumps gave the most trouble.

The jaw-crusher was discarded in favor of high-speed toothed rolls that gave the desired crushing capacity. The rolls are well adapted for sticky ores. To dispense with a man on each shift shoveling ore out of the bin, a 36-in. conveyor-belt was installed to feed the crusher. The opening in the bottom of the bin over the belt was 2 ft. wide, extending clear across the bin. It was closed by means of short pieces of mine rails that could be removed as desired to allow the ore to be drawn out.

The 45 by 15-in. Anaconda-type rolls with smooth shells would clear themselves fairly well if one of the shells had a channel 1 in. wide by $\frac{1}{2}$ in. deep machined in it, but it was troublesome to keep a groove in the shells as they wore down.

One 6-ft. Hardinge ball-mill was intended to reduce the whole tonnage. After plastering the balls to the side of the mill with clay a few times, the mill-men learned by the sound of the mill when it was beginning to choke; feed was then cut off.

Another ball-mill made it possible to keep the rest of the plant going while grinding out the mills, one at a time, and allowed the rolls being set coarser on sticky ore. With clean ore 300 tons per day was sometimes put through one mill.

The ball-mill discharge was classified in two 36-in. Akins classifiers, the oversize fed to two 5 by 18-ft. tube-mills with Komata liners. The tube-mill discharge was classified in a home-made drag-classifier. The small

quantity of material requiring re-grinding included fragments of basalt 'nigger-heads.' This material was almost as hard as the pebbles themselves and of low assay-value. Occasionally enough accumulated in the circuit to be troublesome and was thrown out. A small amount was thought to help grinding. About 80% of the product delivered to the cyanide plant would pass a 150-mesh screen.

Of the mill-head value 80% was dissolved in the crushing-plant. Only small additional extraction could be obtained in the rest of the plant. The real trouble was to remove the dissolved value from the clayey pulp. Accordingly the three 32 by 14-ft. Dorr agitators were changed to thickeners. These settled 300 tons daily of 1 to 10 pulp, as delivered from the crushing-plant, to a specific gravity of 1.15. The 8 sq. ft. of settling area provided per ton of this ore settled in 24 hr. would be sufficient to settle an average Nevada quartz ore to a specific gravity of 1.33. The overflow was precipitated, and the underflow mixed with the barren solution and fed to six 36 by 12-ft. Dorr thickeners, delivering a 1.23 specific gravity underflow to the filters. The 20 sq. ft. of settling area per ton settled in 24 hr. is three times the area required to settle an average Nevada ore to a specific gravity of 1.33. Primary thickeners were held with 2 ft. of clear solution; the secondary thickeners with 6 in. It was impossible to settle the raw Buckhorn ore beyond a specific gravity of 1.26, either in the mill or experimentally.

The maximum capacity of each of the four 14-ft. diam. by 12-ft. face Oliver filters was 50 tons per day, about one-half their capacity on average Nevada ore. An additional filter, 24-ft., had to be installed to filter 300 tons per day.

A sample of Buckhorn ore, dried carefully at a temperature below 110° C., had a specific gravity of 1.9. A higher temperature gave an additional loss of 16% in weight, and entirely changed the physical properties of the ore. The dehydrated sample had a specific gravity of 2.4, and settled and filtered almost as well as a quartz ore. Dehydrating also removed the sticky qualities. Both samples, however, gave the same extraction with cyanide. The temperature of a laboratory electric hot-plate was sufficient to dehydrate a sample nicely. As CO_2 , etc., would not be driven off at this temperature, this loss in weight must be due to water of hydration. With cheap fuel, dehydration before milling would be the best treatment for this class of material. The ore would mill and classify easier, the thickeners and filters would have normal capacity, and dissolved metals would be more completely removed. The temperature of a commercial drier would dehydrate the ore with about the same fuel consumption (100 lb. of coal per ton of ore) as in removing the 18% H_2O if it existed in the form of moisture. The high price of fuel delivered at Buckhorn prevented the adoption of dehydration at this mill. The ore was treated raw at the cost of \$1.59 per ton; total costs were \$2.55 per ton. Power cost \$8 per hp. month.

*Abstract from paper prepared for Arizona meeting of the American Institute of Mining Engineers.

Recent Patents

1,190,012. AMALGAMATOR. Percy A. Robbins, Timmins, Ontario, Canada. Filed Oct. 10, 1914.

1. Amalgamating apparatus comprising a chamber journaled for rotation and provided with an axial opening and a circular axial outlet opening, the chordal planes of segments of the chamber tangentially intersecting the periphery of the outlet opening at different points of the circumference thereof varying in area to cause the surface of contained mercury to alternately approach and recede from the axis of rotation as the chamber is rotated.

1,190,306. ORE-CONCENTRATOR. Rudolph Leonhart, San Anselmo, Cal. Filed Oct. 6, 1914.

An ore concentrator including a conical body mounted for rotation and having a substantially perpendicular portion leading downwardly to the apex of the body and a slightly inclined portion leading upwardly to the apex of the body, there being an outlet at said apex, means for rotating the body in one direction about an axis extending along said slightly inclined bottom portion, means for directing values onto the bottom portion of the table between the outlet and the front of the table, and means extending along the periphery of the table at the uppermost portion thereof, for directing water downwardly toward the outlet to direct into the outlet values adhering to the table.

1,191,271. FURNACE CONSTRUCTION. James A. Bow and Peter Thill, Great Falls, Mont., and Archer E. Wheeler, London, England. Filed Dec. 17, 1914. Serial No. 877,706.

1. In a furnace of the character described, a roof provided with longitudinally disposed expansion joints opening into the treatment chamber, and transverse joints likewise opening into said chamber, the several joints being closed to the atmosphere.

2. In a furnace of the character described, a roof composed of bricks bonded and laid in courses and forming longitudinal

and transverse expansion joints opening into the treatment chamber, and means for closing said joints to the atmosphere.

3. In an arch or roof of a furnace of the character described, a pair of bricks positioned to form a joint opening into the treatment chamber but closed to the atmosphere, and means on the bricks outside the roof for preventing the bricks from dropping into the treatment chamber.

1,188,899. DREDGE-SPUD BRACE. Albert Basil Clardy, Balboa, Canal Zone. Filed July 31, 1915. Serial No. 42,975.

1. The combination with a dipper dredge and a spud connected therewith, of means connected adjacent the lower end of the spud and extending thence upwardly and rearwardly to brace the same, and means temporarily holding the upper end of said bracing means, substantially as set forth.

1,192,478. AMALGAMATOR. Albert E. Vandercook, Alameda, Cal., assignor to California Macvan Company, a Corporation of California. Filed June 16, 1914. Serial No. 845,387.

1. In an amalgamator, a tank, a mercury covered plate arranged in said tank, a hollow armed rotatable structure arranged above said plate, nozzles on said structure directed toward said plate, a pump arranged externally of said tank and arranged to force liquid through said structure and nozzles, a suction pipe for said pump opening into the tank below the normal level of the liquid therein and a feed pipe extending into said tank and terminating below the normal level of the liquid therein and in close relation to the end of the suction pipe, whereby material discharging from the feed pipe is drawn directly into the suction pipe.

1,190,549. PROCESS OF RECOVERING VALUES FROM ORES. Henry Hirsching, Oakland, Cal. Filed November 28, 1913.

A process for recovering copper, silver and gold from roasted or unroasted ores, consisting in acting on the ore with aqueous ammonia, thereby dissolving the copper and the silver, expelling the ammonia from the solution, thereby causing a precipitate from the solution of the black copper oxid and silver oxid, settling and decanting, dissolving the precipitate with sulfuric acid, electrolyzing to deposit copper, recovering the silver, and recovering the gold from the ore residue substantially as and for the purpose set forth.

Mineral Production of California in 1915

The mineral output of California during 1915 was valued at \$96,663,369, for crude materials, including 49 different minerals. Of the 58 counties in the State all but two contributed some mineral product. Compared with the 1914 output, the two notable features are the almost startling increases in some of the metals, and the decrease in petroleum, both in quantity and total value. The result, however, is a net increase in the grand total value of \$3,348,596 over the 1914 total. Of the metals antimony again entered the active list after an absence of several years. Copper increased over 10,000,000 lb. in quantity and \$3,114,192 in value; gold increased \$1,788,800; quicksilver increased 25% in quantity and more than doubled in value; tungsten jumped from a value of \$180,575 to \$1,005,467; zinc gained from 339,641 lb., worth \$20,381, to 13,043,411 lb.

valued at \$1,617,383. Petroleum decreased approximately 12,000,000 bbl. but the average price per barrel was slightly higher, so that the net result was a decrease in value of \$3,983,272.

California yields commercially a greater number and variety of mineral products than any other State in the Union, and possesses latent possibilities in other items so far undeveloped. The total annual value of the output is surpassed by only four other States, they being the great coal and iron producers east of the Mississippi river. California is the sole producer of borax, chrome, and magnesite. For several years the State has been leading all others in gold, petroleum, platinum, and tungsten; but was surpassed in 1915, for the first time, in petroleum by Oklahoma.

During 1916 there is certain to be a considerable increase in the output of chrome, copper, magnesite, tungsten, and zinc. Many new deposits of chrome and magnesite are being mined. Inyo county will swell the tungsten yield.

The following table shows the yield of mineral substances in California during 1915, as compiled from the returns re-

At the coming convention of the American Electrochemical Society to be held at New York on September 27 and 30 one of the sessions will be devoted to 'Made in America' products of the electric furnace and electric cell. These products include many of the most important staples such as copper, aluminum, abrasives, and bleach. While such chemical industries as coal-tar dyes are distinctly European, the electrochemical industry is decidedly American. Aluminum was invented here and put on a commercial basis. The first plant for the electrical synthesis of the elements of the air and the production of artificial fertilizer nitrate was erected at Niagara Falls. Large quantities of abrasives are made in the electric furnace. Other electrochemical products of importance are graphite, phosphorus, hypo-chlorite of lime, magnesium metal, carbon bisulphide, calcium carbide, hydrate of sodium, ferro-silicon, and other iron alloys.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

PROSPECT MOUNTAIN.—RE-OPENING THE GREENBACK.—WOLFTONE SHAFT.—ROBINSON DISTRICT.—HARVARD AND PENROSE SHAFTS.

The first extensive development to be undertaken in the new Prospect Mountain territory since ore was discovered in the Valley adit has been started by Clarence Jarbeau, manager of the Julia Mining Co., now operating the Home Extension and Cloud City properties in the Down Town section. Mr. Jarbeau has organized a strong company, and secured a long term lease on the old Mansfield claims on the north-west slope of Prospect mountain. The property is owned by the Lanphier brothers, operators of the Penn mines on Breece hill. They have done some development on the Mansfield in past years, the most recent work uncovering a large body of iron-manganese ore. A low price was offered for the ore at the time, and it was not profitable to continue work. The ground has been unworked for a number of years. Mr. Jarbeau thinks that the Mansfield, as well as the many other properties on Prospect mountain, will prove as rich in ore as the territory throughout Breece, Fryer, and Carbonate hills, and he has determined on thorough development. The Lanphier adit was driven a distance of 200 ft. This is to be continued 250 ft. farther, when cross-cutting from the main opening will be started at several points. The exposure of iron-manganese ore will be explored at once, and it is thought that shipments of it will be made soon, as there is a good market for it. The Mansfield includes 12 full claims located midway between the holdings of the Valley and that of the Anderson tunnel near Birdseye.

Patrick Mulrooney, owner of the Greenback mine in Graham park, has undertaken another important step in its re-opening. Recently the shaft was re-timbered at the 900-ft. level. The pumping that was carried on through the Wolftone shaft drained the Greenback to this point, where there is a large steam pumping plant that has been under water for several years. The pumps have been repaired and are in good order. It has been decided to drain the Greenback to the bottom level, 1350 ft. A Layne-Bowler deep-well electric pump of 1000 gal. capacity has been purchased for this, and is expected within a week. A 150-hp. motor has been installed on the 900-ft. level for propelling the sinking pump. The water will be raised by the sinker to the 900-ft. level, where it will discharge into the old steam plant, which in turn will deliver to the surface. It is thought that the dow will not exceed 500 gal. after the shaft has been drained. The Colorado Power Co. has completed the erection of a line to the Greenback, and linemen are now erecting a transformer-house at the property. Transformers have been delivered for installation, and everything will be in readiness for operation as soon as the pump is installed.

The Western Mining Co. is preparing to continue the draining of the Wolftone and surrounding mines to a depth of 1950 ft., the bottom of the Wolftone shaft. The pumping that has been done in this shaft has already reduced the water-level in the Greenback, Mikado, and Pyrenees 150 ft., and has completely drained the Robert Emmet. With further draining prepared for the Greenback and the Mikado, this section of the district will soon be open for deep mining.

The old Robinson Kokomo district, just over the line in Summit county, is in the midst of the greatest boom that has

been known for some years. A year ago there was nothing doing throughout the entire district. Two or three old properties were active, but they were producing only a small tonnage, employing a few men. Now there are 14 mines working, all of them shipping heavily and employing a total of 250 men. The bulk of the ore being extracted is a lead-zinc sulphide, which is shipped to the Progress mill near Robinson. This plant, formerly known as the Wilson mill, has been completely overhauled and re-modelled by the Progress people, and at present is one of the most efficient separation plants for lead-zinc ores. It is a combination process of flotation that gives unusual results. The mill has a capacity of 500 tons and is working regularly.

A rich gold, silver, and lead strike has just been made on the Columbine property near Robinson, which is under lease to some Leadville mining men. A 3-ft. vein assaying 4 oz. gold, 786 oz. silver, and 10% lead has been opened. Several shipments have been made. Estimates on the returns from the ore now at the smelter give \$15,000 a 25-ton carload, an average value of \$600 per ton. The Columbine is one of the oldest mines in the Robinson district, and has just been re-opened by lessees after years of inactivity. It has produced lead and silver heavily, and was known to contain rich lead-zinc veins. The present operators proposed to develop the zinc deposits, and were proceeding with this work when they discovered the silver ore. One of the men was digging a drain at the bottom of a 70-ft. slope when he found the ore. Other prospecting exposed the vein for 11 ft. A large tonnage is being extracted, and the mine has every indication of becoming one of the richest producers of the district.

The water problem at the Harvard property on Fryer hill, being exploited by the U. S. S., R. & E. Co. has finally been solved. The flume that was constructed through part of Evans gulch, which is now carrying the stream past the Harvard, has effectively blocked the surface water that was causing considerable trouble. Immediately after the water had been turned into the flume, the flow in the shaft decreased from 300 to 500 gal. per minute. The mine is now being rapidly drained. Preparations are being made for sinking the shaft another 300 ft., making it 1040 ft. deep.

Drainage of the Penrose shaft and workings in the Down Town basin is now complete. The large 4-stage electric centrifugal station-pump of 2000-gal. capacity has been installed at the bottom level, and connected with its 650-hp. motor. A water-column has been attached, and the pump is now steadily throwing a large stream to surface against a head of 870 ft. One of the sinkers has been removed from the shaft, this compartment being used for hoisting. The flow, which is estimated to be between 2500 and 2800 gal. per minute, will be handled by the station-pump at the bottom, and one sinker working in relay with the relief pumps at the 450-ft. level. Mining in the old workings is extending. Surface rights to a large area surrounding the Penrose have been purchased for dumping. Most of this ground has been occupied by residences; the buildings are being moved to other locations. It is officially reported that ore has been exposed in several places and that shipping will be started in a short time.

Returns from the Pittsburg mine in lower Russell gulch, Gilpin county, continue rich. Two recent lots yielded 6.61 oz. gold, 7 to 8 oz. silver, and 6.5 to 16.5% copper. This was mined from a depth of 900 feet.

VICTORIA, BRITISH COLUMBIA

SIX MONTHS' PROGRESS IN MINING AND METALLURGY.

Generally, the mining industry of this Province made progress during the first half of 1916. The chief trouble recorded was in the latter half of June, there being delay in delivery of ore from the silver-lead-zinc mines shipping to the Consolidated Mining & Smelting Co.'s works at Trail, rapidly melting snow having caused floods that damaged railways and wagon-roads and, in several instances, washouts that broke water-supply lines to mines and concentrating mills and in other ways interfered with mining and milling operations over a period of two to four weeks. The second half of the year opened with labor disputes in the Crownsnest coal-mining region, the colliery employees having demanded a higher "war bonus" than the operators were willing to concede, consequently there was a stoppage of work for a short time and a resultant break in coal and coke production. The shortened supply of the latter made necessary a curtailment of operations at copper-smelting works. However, a settlement is in sight.

As indicating the progress made in Kootenay district this year, the figures showing the ore receipts at the Trail smelter are, on the whole, satisfactory. In making the following comparison of the totals of ore-receipts in the first half of each of three years, 1914, 1915, and 1916, it should be kept in mind that the outbreak of War in Europe did not affect figures for the 1914 period quoted, since War was not declared until after the close of that half-year. It did affect the 1915 period, however, and so far as a few mines previously producing regularly but not operated since the outbreak of War, to some extent the 1916 period also. The several half-yearly totals were as follows: to June 30, 1914, 183,427 tons; June 30, 1915, 217,627 tons; and June 30, 1916, 245,466 tons. The increase in receipts was largely from mines operated by the Consolidated company itself, custom ores having increased only from 38,131 tons in the 1914 half-year to 40,265 in the corresponding period of 1916, the latter having been a substantial improvement on the 1915 figures, which were 21,511 tons to June 30 of that year. The total quantity of custom ores received from British Columbia mines during the first half of 1914 was 29,464 tons, compared with 6386 tons in the corresponding months of 1915, and 25,258 tons in that of 1916. On the other hand, receipts from mines in the United States, chiefly in the northern part of Washington, were 8667 tons in the 1914 period, 15,125 tons in that of 1915, and 15,997 tons in that of 1916. In this connection it may be mentioned that ores from the State of Washington have also been sent to smelting works in the Boundary district of British Columbia, though these and Trail will hereafter have a strong competitor in the lately remodeled reduction works at Northport, Washington. Another thing to be taken into account is that the larger mines in Slocan district have this year taken advantage of the high prices for zinc, as is seen by the following comparison: zinc ore and concentrates shipped during the first half of 1916 included 5476 tons for the Standard, 2220 tons from the Lucky Jim, 1647 tons from the Galena Farm, and 1110 tons from the Slocan Star, a total of 10,453 tons, compared with only 83 tons from all four mines in 1915. The figures for the Surprise mine are the other way; its 1915 total, to June 30 was 3058 tons of zinc product, while that for this year is only 185 tons, the destruction of the concentrating mill by fire having prevented production this year pending completion of a new mill.

The foregoing figures do not include ore production in Boundary and Coast districts, in which are situated the larger copper mines of the province. Full particulars are not available just now, but an idea of progress may be obtained from the following figures showing the amount of copper produced by the Granby company, practically all from its own mines in the two districts mentioned. In January, 3,122,879 lb.; February, 2,690,265 lb.; March, 3,555,411 lb.; April, 3,950,469 lb.; May, 4,727,929 lb. The Britannia company made an increase.

Summarizing the position so far as concerns some of the larger producing mines in Kootenay district, it is noteworthy that East Kootenay mines sent to Trail in six months of 1916 37,094 tons of ore—nearly all from the Sullivan mine—compared with 10,766 to June 30, 1914; and West Kootenay mines 189,972 tons against 163,073 tons. In regard to West Kootenay, there was an increase from Rossland mines from 128,000 tons in the 1914 period to nearly 172,000 tons in that period of 1916; while on the other hand receipts at Trail from mines in Ainsworth, Slocan, and Nelson divisions decreased from 35,100 tons in the first part of 1914 to 16,700 tons in that of 1916. Yet on the whole, there is believed to have been an appreciably large

MILL AT THE SEA-LEVEL MINE NEAR KETCHIKAN, NORTH OF THE BRITISH COLUMBIA BOUNDARY.

increase in ore production for the province compared with 1914 and 1915.

Metallurgical progress has been keeping up with that of mining. The most striking changes are those made at the Consolidated company's works at Trail. Accompanying a picture of the new zinc-refining works at Trail used lately in New York newspapers was the statement that Trail is the only place in the world where gold, silver, lead, zinc, and copper are all refined. Whether this be so or not, the fact remains that operations at Trail now include the electrolytic refining of lead and zinc, and probably copper if the new plant has been completed, while the refining of gold and silver has been done there for years. There is little if any change at Boundary district copper-smelters, long noted for their efficiency; a higher gold-saving standard has been reached at the Hedley Gold Mining Co.'s 40-stamp mill and cyanide plant; in Slocan district, several of the older wet-concentration mills have been much improved and two or three new ones erected and equipped, flotation being provided for in several instances; it is claimed that the French zinc-saving process will soon be in successful operation at Nelson; the Britannia company has made striking progress with its enlarged mill, using the M. S. flotation process on silicious copper ore; and the Granby's smelter at Anyox is producing copper at low cost, with complete satisfaction to the management.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the best press.

ALASKA

FAIRBANKS. From the Eldorado mine at the head of Cleary creek, 16 tons of lead ore was shipped to smelters last month. This is the first time that galena has been sent from the Tanana valley.

LIVENGOOD. A preliminary report on the Tolovana district, by Alfred H. Brooks, has been published as Bulletin 642-G of

limestone, and black and red slates, with some chert beds. The gold-bearing gravels are largely greenstone and chert, as well as quartz. The deposits are in four classes, namely, deep, bench, and creek gravels, and slide material. The deep channel gold of Livengood creek is dark colored, and is worth from \$18.75 to \$18.90 per oz. This channel constitutes the most continuous placer deposit that has been developed here, what seem to be parts of the same channel having been

opened at several places for 3 to 4 miles. The richest gravels developed are in this channel and in the streams cutting across it. The town of Livengood is the commercial centre of the district. There is abundant timber available, but hardly enough water for sluicing.

ARIZONA

GLOBE. During the first half of 1916 the Arizona Commercial produced 2,251,000 lb. of copper and a net profit of \$334,000. Development on No. 14 level is opening more and better ore than above. Machinery for the power-plant is being delivered at the mine.

HUMBOLDT. The Consolidated Arizona Smelting Co. reports as follows for the second quarter of 1916:

Ore reserves on July 1, tons	
(increase of 200,000)...	500,000
Mill treated, tons.....	20,884
Smelter reduced, tons (including custom ore)....	26,077
Copper output, pounds....	2,450,000
Gold, ounces	1,576
Silver, ounces	35,788
Net profit	\$249,503

All figures are a considerable increase over those in the first quarter, the profit being \$88,546 greater. As mentioned in last week's issue, the crushing-plant, sample-mill, and ore-bins at the smelter were burned on June 9; but this is quickly being remedied.

NOGALES. In its issue of August 15 *The Oasis* has a special mining edition describing conditions in Santa Cruz county. A map shows the position of the mines.

OATMAN. At a vertical depth of 110 ft. in the Lexington mine a lode 9 ft. wide, of good value, has been cut. Of this 30 in. assays \$12.50 per ton. This strike is the best found so shallow in this district.

At the Boundary Cone the lode is 26 ft. wide.

PATAGONIA. To develop a gold-silver-lead-zinc property 27 miles north-east of Nogales and 25 miles south of Patagonia, the Santa Cruz-Bisbee Mining Co. has been formed in the Warren district. J. F. Walker is in charge.

the U. S. Geological Survey. The region lies in the headwater territory of Tolovana river, which flows southward into the Tanana, and in the upper basin of Hess creek, which flows westward into the Yukon. Gold placers have been found and are being developed there. Production so far has been confined chiefly to the ground on Livengood creek. The present rush set in during 1914 and 1915. From 19 properties the output last year was \$80,000. The topography of the country shows the characteristic flat-topped ridges of the Yukon-Tanana upland. The bedrock is mainly cherty crystalline

CALIFORNIA

The California Metal Producers Association and the California State Tax Commission met in joint session at the offices of the Association on August 19 for the purpose of discussing plans providing for a uniform system for mine assessment and taxation. Several proposals were discussed. Plans to be finally agreed on will be submitted to the Commission for its further consideration.

DEDRICK. At the Globe Consolidated work has been resumed in charge of H. M. Ball. Part of the 20-stamp cyanide mill is to be kept working. A lower adit is being driven to open the veins at depth.

GRASS VALLEY. At the Golden Gate mine \$5000 has been spent since June 29 in reconstruction of the mill, 800-ft. surface tram, and other work. The plant now has a capacity of 60 tons daily. It is said that the Pacific Western Commercial Co. is to treat tungsten ore brought from other districts.

The old placer town of You Bet was considerably burned last week.

HEROULT. At the Noble Electric Steel Co.'s smelter one furnace has been in continuous operation since April 14 making ferro-manganese and other products.

KENNETT. The Mammoth company is making good progress in driving the 5000 and 4000-ft. adits in its Mammoth and Friday-Lowden mines.

In the Bully Hill area of the copper belt a dozen properties are busy. The Green Horn is to install motors.

ORVILLE. On August 24 the Natoms company commenced re-dredging tailing on the Feather river. This ground was dredged in 1909. G. H. Thurman is in charge of this new work.

YREKA. The Eliza, one of the oldest gold mines in Siskiyou county, 12 miles from this place, has recently been examined by an engineer. Seven years ago the property was acquired by W. B. Shearer, R. H. De Witt, and A. E. Junker of Yreka, with O. H. Lawson in charge. A considerable amount of exploration was done since then, especially on No. 5 level, which is in 1700 ft., 1000 ft. of which contains \$5 per ton free gold, and is heavily mineralized. Ore reserves are estimated at 70,000 tons. A 30-ton mill-test yielded \$5 per ton free gold, the feed being \$7.69 per ton. Facilities for mining and working the 10-stamp mill are abundant. A lower adit is to be driven, also additional plant is proposed.

COLORADO

According to the deputy State mining commissioner, M. B. Tomblin, there are 15,000 men employed at Colorado mines, an increase of 50% over the number in the same period of 1915. There were 26 fatalities, a decrease of 40%.

ALMA. In the new tungsten field in Park county there is great activity. Several mines are opening well.

OURAY. The most active of the new properties commencing work is the Vernon near Ironton. At present the company is installing a new hoist and is building a bunk-house, boarding-house, and shaft-house. At 69 ft. depth there is from 10 to 12 ft. of high-grade enargite ore. A. G. De Golyer is manager.—The Revenue mine has 20 men cleaning-up and re-timbering, preparatory to starting on a large scale.—The Ouray Tungsten Mining Co. has leased part of the Wanakah mill below Ouray, and will concentrate its ore there until it builds its own mill at the property. G. W. Barnhart is manager.

PLACERVILLE. The Primos Chemical Co. has withdrawn its miners from the vanadium mines above Placerville, and arranged them between the property at a point a short distance below Sawpit and at the Bear Creek mines. There is plenty of ore developed and being extracted to keep the plant at Vanadium working at full capacity. Labor-saving devices are being put in. At the mine and mill there are 100 men.

KANSAS

PITTSBURG. At the Joplin Ore & Spelter Co.'s zinc smelter two blocks of retorts have been stopped indefinitely.

MICHIGAN

THE COPPER COUNTRY

The Calumet & Hecla company reports as follows for July, in pounds:

Mines	July	7 months
Almreek	1,741,097	13,292,292
Allouez	744,624	5,862,531
Calumet & Hecla	6,172,908	44,330,490
Centennial	190,262	1,459,959
Isle Royale	980,574	7,916,340
La Salle	93,580	726,188
Osceola	1,818,241	11,609,680
Superior	183,020	1,941,485
Tamarack	476,652	3,923,077
White Pine	277,941	2,468,413

MISSOURI

JOPLIN. Zinc ore advanced \$5 per ton last week, the top price being \$70 per ton for 60% content. The output of the region was 4063 tons of blende, 364 tons of calamine, and 822 tons of lead. The total value was \$309,142, and for 33 weeks \$22,898,046. A shortage of water is bothering mines and mills in the district, several of them being closed until rain or until supplies are obtained.

A 300-ton mill is to be erected by the Bell Mining Co. at Duenweg. A new shaft is down 105 ft., ore occurring at 140 ft. The ore contains up to 15% zinc.

MONTANA

BUTTE. Connection has been made at 2600 ft. in the Tuolumne, and mining is to commence on that level. The output can be increased 25 per cent.

Wages in August will be \$4.50 per shift on account of copper being over 25 cents per pound.

NEVADA

FAIRVIEW. In June the Nevada Hills company made a profit of \$8738, and \$19,155 in the first quarter. Quick assets amount to \$302,000.

HORN SILVER. At the Hardwick-Reid lease on the Orlean property, from 12 to 36 in. of \$80 ore has been opened, also a foot-wall seam of several inches assaying 5 oz. gold and 1700 oz. silver per ton.—At the Horn Silver company's mine a 40-hp. hoist has been installed. The shaft is 510 ft. deep. Plenty of milling ore is opened.

(Special Correspondence.)—The Pocahontas mine has been bonded for \$50,000 from M. Feeney by F. W. Cole and D. W. Minier, president and general manager respectively of the Azalia Mining Co., operating the Azalia and Surprise properties in this district. The Pocahontas is between the Yellow Pine and Red Cloud mines, and has been opened by a 300-ft. adit and 25-ft. shaft. The latter is to be deepened and equipment installed.

The Bullion Mining Co., composed of Salt Lake people, has taken over the Bullion mine and is preparing for a large output. The Bullion has been extensively developed and a considerable tonnage of shipping ore is said to be ready for extraction.

Shipments of gold-platinum ore are being made at the rate of \$12,000 per month from the Boss mine. The company is said to have devised a process for treating its ores, and will probably erect a plant in the near future.

Five concentrating plants are being operated in the district, and two more have been practically decided on. In addition to the ore treated by concentration, heavy shipments

of silver-lead and zinc ores are being made to custom smelters from a number of properties. Several important deals have been made recently, and the district is recording greater activity than ever. While the Yellow Pine continues to be the principal producer, the Anchor, Green Monster, Surprise, and several others are yielding well. On August 10 the Yellow Pine paid an extra dividend of 10c. per share. This makes \$750,000 for the current year, or 75c. per share. The company has \$84,000 cash. In June the output was 200 tons of lead and 1500 tons of zinc concentrate, giving a net profit of \$51,430.

Goodsprings, August 19.

JARRIDGE. There are 290 men employed at this place, where some encouraging strikes have been made recently.

TONOPAH. Some July returns were as follows:

Mine	Tons	Oz. bullion	Profit
Belmont	11,828	237,459	\$107,000
Extension	8,139	180,240	69,209
Jim Butler	4,752	25,829
Tonopah	8,019	111,565	26,763

Last week the West End mill treated 828 tons of its own and 455 tons of custom ore. As to the status of the Jim Butler-West End litigation the Supreme Court of Nevada has granted a motion made by the Jim Butler attorneys to keep the proceeds of the ore extracted from the disputed territory impounded until the further adjudication of the case by the Supreme Court of the United States. In consequence, the returns from this ore will be tied-up for some time.

The district's output last week was 8916 tons worth \$186,568.

VIRGINIA CITY. Two new sinking pumps, motor-turbine type of combined capacity of 1000 gal. per minute, have arrived at the C. & C. shaft of the Pumping Association. The pumps are to be installed at 2900 ft. in the Ophir-Mexican winze to drain that level.

NEW MEXICO

ALBUQUERQUE. A year or more ago interest was renewed in the Carocito copper district, near Scholle, a station on the A. T. & S. F. railway, 50 miles south-east of Albuquerque. The ore is of the 'wood-copper' type, in sedimentary formations. Unlike most such bedded deposits of copper in the Western red beds, however, it lies mainly in limy-shales. Several horizons appear within a stratigraphic thickness of 100 ft. or less, but none is more than 2 ft. thick—usually not more than 10 inches. The field has been prospected over an area of some 10 sq. miles, according to the State geologist, Charles T. Kirk, though only one vertical shaft has been sunk below 25 ft. The Pritchard-Cavin mine is down 72 ft., 61 ft. of which is in ore containing from 7 to 9.5% by carload lots. Near the surface this ore is dominantly malachite, but soon passes into azurite, of better grade, and is now largely chalcocite at the shaft bottom. This ore is shipped without picking or other concentration to El Paso. Nearly all other properties are hand-cobbling ore from near surface workings, mainly open-cuts.

LOMBARD. It is probable that the Eighty-Five Mining Co. near here will erect a flotation plant in the near future. Tests have been made for some time.

(Special Correspondence.)—The Socorro Mining & Milling Co. shipped 1700 lb. of gold and silver bullion to Mint and several tons of concentrate to smelter, clean-up from the last half of July.

With good milling ore in the Eberle, and two different parts on the Clifton mine yielding profitable ore, the Oaks company is steadily proving the value of the 'Queen Vein' or 'Mother Lode' of the district, in which the management has always had great faith.

The new 3-compartment 6 by 16 ft. shaft of Mogollon Mines Co. has reached a depth of 820 ft. This company has started work on a board flume to keep tailing out of creek, the intention being to extend it to the present tailing storage-dam on Mineral creek, some 1 mile below and permanently keep

residue out of streams. The different companies have spent several thousand dollars in recent years, and now have the tailing problem well under control.

The companies of Mogollon have completed survey of the proposed new road to the Arizona line to connect with the route to Clifton; early action in this matter is expected.

Work on the Good Luck claims was recently resumed by the owners, Lauderbaugh and Thorlston. A 250-ft. cross-cut adit encountered the contact at depth of 170 ft., and it is understood the showing is satisfactory.

During first half of August the Mogollon Mines Co. treated 2013 tons of ore, producing 1600 lb. of gold-silver bullion and several tons of concentrate. The first section of tailing flume has been completed and is now in commission.

Flotation experiments made at one of the local mills show that the ores from the northern end of the district will give a high extraction. Whether or not other mines here will be aided by this method has not been fully determined. Careful tests are being made under various conditions with the hope of improving on and doing away with the cyanide process.

Mogollon, August 22.

TEXAS

(Special Correspondence.)—It is announced that the work of exploring this section for potash by the U. S. Geological Survey is soon to be resumed. The Government commenced boring for potash near Cliffside more than a year ago. It is considered that this part of the panhandle of Texas contains potash in commercial quantities.

Cliffside, August 25.

UTAH

ALTA. Progress in diamond-drilling by the Emma Copper Co. is between 45 and 50 ft. daily. The first hole, at an angle of 62°, is down below 500 ft. J. J. Beeson is the geologist in charge.

MORGAN. The Western Oil & Shale Co. is being organized by Chicago, Salt Lake City, and other people to operate extensive holdings of oil and shale land in Sanpete county. The shale is said to contain from 10 to 16% of paraffin. G. T. Stenhouse of Morgan is the leading spirit. About \$40,000 is to be spent.

SALT LAKE CITY. On account of Utah smelters putting an embargo on ore-supplies there is probably to be an investigation into the erection of another smelter nearby.

TINTIC. Shipments from 24 concerns last week amounted to 5400 tons. The Tintic Milling Co. sent out precipitate worth \$24,000. The plant is treating 100 tons daily, to be increased to 300 tons when the new roasting-furnaces are erected.

WASHINGTON

The Concomully and Ruby mining districts are in the north-central part of Washington, about 40 miles south of the Canadian border. The ore deposits were discovered in 1886, but production has been small owing to lack of transportation facilities, difficulty in treating complex ores, and the decline in the price of silver. The most valuable ore deposits in these districts consist of quartz veins which occur in schists near the areas of granite or at the contact of schist and granite. The ore minerals, pyrite, zinc-blende, chalcocite, and gray copper, carry silver and a little gold. A report on these districts, by Edward L. Jones, Jr., just published by the U. S. Geological Survey as Bulletin 640-B, contains a study of the geology and mineralogy of the region and detailed descriptions of the individual mines and prospects.

NORTHPORT. A statement issued by the Electric Point Mining Co. shows that the mine was discovered in June, 1915, and started producing lead ore in July, 1916. The company has 1,000,000 shares, 100,000 being in the treasury, 600,000 going to the incorporators. Cash on July 31 was \$13,537. From July 31 to August 11 shipments to Trail amounted to 533 tons, the present output being 75 tons daily.

CANADA

BRITISH COLUMBIA

GRAND FORKS. The Seattle and Loyal Canadian properties, 8 miles north of here, of which little has been heard for years, have been bonded by R. Clarke and others to E. E. Martin of San Francisco and associates for \$125,000. On the daily shipment of 50 tons of ore to the Granby smelter there will be paid a royalty of 50 cents per ton. J. McKay is in charge.

ONTARIO

COBALT. On September 15 the Kerr Lake will distribute 25c. per share, equal to \$150,000. This makes \$450,000 for 1916, and \$6,570,000 to date.

The Temiskaming shaft is down 1250 ft., nearly to the diabase-keewatin contact.—At the Beaver Con. exploration continues below 1600 feet.

PORCUPINE. The McIntyre mill is to be enlarged to 600 tons per day. The present capacity is 12,000 tons per month.

During the 28 days ended July 14 the Hollinger Consolidated made a profit of \$215,165 from 46,018 tons of ore. This averaged \$9.15 per ton. Costs totaled \$3.99 per ton.

Open-cut work is supplying two-thirds of the Dome ore. The new central shaft is causing some delay. A great quantity of ore is being broken on No. 4 and 5 levels. On No. 7 the orebody is 240 ft. wide.

Diamond-drilling at the West Dome is reported to be encouraging.

An orebody 40 ft. wide and 90 ft. deep has been opened by drilling at the Dome Extension.

KOREA

The July clean-up of the Oriental Consolidated was valued at \$128,750.

PHILIPPINE ISLANDS

Following is the statement of production of the Benguet Consolidated Mining Co. for the first half of 1916: The mill treated 8030 tons of ore, containing \$161,615, or practically \$20 per ton. The actual bullion recovered and shipped to mint was \$140,487 by mine assays, or an average of \$17.50 per ton. The total amount of bullion shipped was 10,539 oz., or equal to an average value of practically \$13.50 per ton.

The AMERICAN CHEMICAL SOCIETY will hold a meeting at New York on September 25 to 30, in conjunction with the Second National Exposition of Chemical Industries. Charles H. Herty, of the University of North Carolina, president of the Society, will open the Exposition on the 25th. His address will review the history of chemistry and the chemical industries of this country and outline developments since the outbreak of war in Europe. The presidents of co-operating societies, such as the American Electrochemical Society, American Institute of Mining Engineers, and American Paper and Pulp Association, will follow Dr. Herty with speeches of welcome and reviewing the progress made in the industries represented by them.

The UNIVERSITY OF CALIFORNIA Bulletin for July, of 269 pages, covers the announcement of courses for the academic year 1916-17 in the colleges of mining, chemistry, civil engineering, and others.

Instead of holding its 21st annual meeting on the Menominee Range, the LARI SUPERIOR MINING INSTITUTE will make a trip to the Birmingham district of Alabama on March 13, 1917.

The U. S. CIVIL SERVICE COMMISSION states that in the open competitive examination for junior mining engineer, to be held on October 11 and 12 on the subject of 'mining operations,' there will be two series of questions, one on coal and the other on metal mining. Competitors may be examined in either one or both of these.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

P. K. LUCKE has gone to Cuba and Costa Rica.

GEORGE F. BRIDGER has returned to Los Angeles from Miami, Arizona.

J. B. RISQUE has resigned as manager for the Tennessee Copper Co.

E. E. FREE of Baltimore is examining potash deposits near Blair, Nevada.

R. B. LAMB is in Nevada and California and will be away from New York for two weeks.

B. S. BUTLER is investigating the Cottonwood districts of Utah for the U. S. Geological Survey.

W. C. OREM, general manager for the Nevada-Douglas Consolidated Copper Co. is visiting the mines.

CHARLES B. CROKER is examining the Alvord mine north of the Calico district for Los Angeles people.

J. A. WILKINSON has been elected president of the Chemical, Metallurgical and Mining Society of South Africa.

ROSCOE EDVYAN will leave the Messina Transvaal Development Co. in South Africa, when his contract expires on Sept. 16.

A. G. DE GOLYER, formerly of New York, has been appointed general manager for the Vernon Mining Co. at Ironton, Colorado.

J. L. BRUCE, general manager for the Butte & Superior, was recently operated on for appendicitis, at Rochester, Minn., but has returned to Butte.

G. H. WOHLHAUPTER, formerly with the Utah Copper Co., will conduct flotation experiments for the Stimpson Equipment Co. at Salt Lake City.

JAMES A. LEWIS, JR., assistant chief engineer for the Calumet & Arizona, was severely injured on the 1300-ft. level of the Junction mine on August 16.

HARRY HUNTINGTON MILLER, manager for the Compañía Anónima Minera Lo Inceñible, El Callao district, Venezuela, has resigned and is in Los Angeles.

CHARLES T. KIRK, state geologist of New Mexico, who has been in the Mid-Continent oil-field and in Yavapai county, Arizona, has recently returned to Albuquerque.

E. W. BELLARI, safety engineer of San Francisco, has returned from visiting the coal mines of Pennsylvania, and the iron and copper mines of Michigan and Minnesota.

N. H. EMMONS, 2nd, for 18 months assistant manager and for three years manager for the Tennessee Copper Co., has again been appointed manager, with residence at Copperhill.

JAMES MACNAGHTON, vice-president and general manager for the Calumet & Hecla Mining Co. will reside in New York. JOHN KNOX, general superintendent, will be in charge at Calumet.

W. EARL GREENOUGH, has resigned as managing director of the Marsh Mines Consolidated, of Wallace, Idaho, to engage in independent practice as consulting mining engineer with headquarters at Spokane.

Obituary

ALEXANDER FRASER, metallurgist at the plant of the Cia. Min. de Angelitas, Pozos, State of Guanajuato, Mexico, was killed on July 31 by revolutionists under Nateras. Fraser had been 20 years in Mexico. He was 48 years of age, and leaves a wife and two children in London.

THE METAL MARKET

METAL PRICES

San Francisco, August 23.

Antimony, cents per pound.....	14
Electrolytic copper, cents per pound.....	28.75
Pig lead, cents per pound.....	6.75—8.00
Platinum: soft and hard metal, per ounce.....	\$65—69
Quicksilver: per flask of 75 lb.....	\$77
Spelter, cents per pound.....	12
Tin, cents per pound.....	41
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, August 23.

Antimony: 50% product, per unit (1%, or 20 lb.).....	\$1.00
Chromite: 50% and over, Loc. cars California, per ton, 13.00—16.00	
Manganese: 50% product, Loc. cars California, ton, 12.00—16.00	
Magnetite: crude, per ton.....	7.00
Molybdenum: 50% and over, per pound.....	0.60—1.15
Tungsten: 60% W.O., per unit.....	15.00

While optimism prevails at Boulder, Colorado, the Rare Metals Ore Co. at Rollinsville has reduced its tungsten quotations to \$10 per unit for 60%, \$8.50 for 50%, \$7.50 for 10%, \$6.50 for 30%, \$5.50 for 15%, and \$3.90 for 5% product.

Platinum bulletin of the U. S. Geological Survey has been issued; also that on bauxite and aluminum.

EASTERN METAL MARKET

(By wire from New York.)

August 23.—There is a good demand for last-quarter copper; lead has an easier tendency; spelter is dull, with second-hands weak.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending
Aug. 23.....	66.37
" 24.....	66.31
" 25.....	66.25
" 26.....	66.12
" 27 Sunday.....	66.10
" 28.....	66.50
" 29.....	66.50

May	58.21	49.87	54.27	Nov.	49.12
June	56.12	49.02	53.64	Dec.	49.27

It might be said that the tone of the silver market is steady, a slight downward movement indicating little. Earlier in August, American offerings in London had shrunk appreciably, China was not selling, and supplies of metal were not forthcoming from other sources, resulting in less active business. Stocks in Shanghai have gained from 30,500,000 oz. and 17,000,000 Mexican dollars to 32,000,000 oz. and 116,000,000.

On August 27 the "Ecuador" took silver worth \$591,600, say 900,600 oz., from San Francisco to the Orient.

COPPER

Prices of electrolytic in New York, in cents per pound.

The U. S. Geological Survey has issued its "Press Bulletin" on the production of spelter in the first half of 1916. Details are given of output, consumption, stocks, exports, imports, and smelter capacity.

Zinc ore imported into the United States in the period January-June 1916, was as follows, in short tons:

From	Quantity	Zinc-content	Value
Canada	12,663	5,187	\$314,524
Mexico	79,663	25,471	3,254,001
Spain	38,239	16,006	1,051,315
Italy	7,525	3,283	213,275
Australia	83,775	38,133	2,225,790
Other countries	9,780	5,827	\$99,160

*Including China and Japan.

Exports of spelter and sheet-zinc totaled 58,097 tons of domestic, and 20,197 tons of foreign metal.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds.

Tin is firm at 29 to 30 cents.

Eastern Metal Market

New York, August 23.

All metals except tin have advanced in price, and have been or are in strong demand.

Copper has advanced considerably on large foreign and domestic buying.

Zinc is higher with a good business done for foreign and domestic consumption, which has slackened somewhat.

Tin is a little lower but firm and quiet, the position being strong.

Lead has risen on active demand and sales to foreign and domestic consumers.

Antimony sales have been large and the price has advanced. Aluminum is quiet and dull at 58 to 60c. Sheets are quoted at 80 to 85c., two to six weeks' delivery.

In the steel market, pig-iron is now the leader and buying has been on a large scale, particularly steel-making grades. Enormous orders for shell and other war material, with deliveries running 6 to 10 months ahead, have been booked, and it is evident that the Allies want much more steel from this country. The recent increase in domestic buying leaves the total shorter than some steel producers expected. There are signs in the building trade that high prices for steel are not to retard new structures, and car re-building is a factor rather than new cars, orders with 25,000 to 30,000 tons wanted for the former. Prices generally are stiffening.

COPPER

The rumors reported last week of large inquiries from both foreign and domestic sources have developed into an extensive buying movement, the amount involved being hard to determine. It is considered in some quarters that the 250,000,000 lb., estimated as the probable purchase of the Allies to cover their requirements, during part at least of the next six months, has already been arranged for and that at least 25,000,000 lb. has been sold for domestic account. In any event the purchases have been large for last quarter and near-by delivery and prices have advanced sharply, rendering the market very strong. Spot electrolytic yesterday was hard to buy, and was quoted at 27c. cash, New York, with Lake ingot nominal at 27.25c., also an advance. At present the market is quieter with consumers apparently well covered. Sellers dominate the situation and they are disinclined to make any concessions. Some sales are reported for early 1917 delivery. Electrolytic for last quarter is obtainable at 26 to 26.50c. The rush to provide for needs has brought the market back to the high prices of last May. The London market yesterday was £127 against £126 last week. August exports so far are 22,544 tons.

ZINC

The activity that characterized the early days of last week soon resulted in extensive buying on the part of foreign and domestic brokers, brass mills and perhaps second-hands. The price advanced accordingly until prompt metal was quoted yesterday at 9.75c. New York, and 9.50c. St. Louis, with last quarter at about 1c. per month below these prices. Just now demand has slackened, and the market is quieter but firm. It is thought that there is less metal in second-hands, and that producers are in a better sold up condition than when the last advance was manifested. A feature of the week's business has been the buying of large quantities of high-grade spelter that has been a drug on the market for some time. The recent spell of buying has been well distributed among users of prime western, brass special, intermediate, and high-grade metal. Exports to August 22 were 6990 tons.

Some interest has been manifested in the announcement that Great Britain has entered into an agreement with Australia to take 100,000 tons of zinc concentrate and 45,000 tons of

spelter yearly for the period of the War and for 10 years thereafter. Full details have not been made public.

LEAD

The spurt, which was noted early last week, developed into a heavy demand from all quarters, and sales are estimated by one broker to have attained an aggregate of about 10,000 tons last week. The buying was for foreign and domestic consumers, especially for prompt and August delivery. The latter circumstances was due probably to the fact that buyers' stocks had been decidedly depleted, necessitating their entry into the market. The demand grew until it attained such proportions that the outside price passed that of the A. S. & R. Co., which immediately raised its quotations on Thursday to 6.25c. per lb. New York. On persistent demand the same interest again raised its price to 6.50c. per lb. on Friday. It is believed now that sellers are pretty well sold-up, and that there is not much lead left for shipment within a month. For the first part of this week quietness has prevailed, with buyers refraining from climbing and sellers not inclined to sell. A small quantity is reported as having been sold at St. Louis as high as 6.55c., and a small lot at 6.65c., with special circumstances attending the latter transaction. One broker reports the leading interest as out of the market for early delivery metal. Another statement carries the conviction that the independents are better sold-up than they have been at any time since the boom in March and April, leaving the opportunity favorable for the big interest to raise its price again.

The general strength of the lead market is indicated by the rather high quotations on an inquiry for the Frankford Arsenal for 300,000 lb., the Nassau S. & R. Works, quoting 6.72½c. per lb., American Metal Co., 6.79c., Nathan Trotter & Company, 6.83½c., and Federal White Metal Co., 6.85c. It is noticeable that neither the A. S. & R. Co. nor the leading independent producers were competitors.

TIN

Quietness dominates the market, and there is a distinct absence of any excitement or any anxiety to sell or buy tin. The necessary protection of contracts or the covering of short sales has resulted in some business, but the tonnage involved has not been of large proportions. Despite the quietness, the week has been featured by steadiness in prices with no indications of easing anywhere. Yesterday Straits tin was obtainable at 38.50c. New York, and Banca tin at 37.50c. and steadier. Arrivals this month, including those for the 22nd, have been 3137 tons, with 3110 tons afloat.

ANTIMONY

The events of the past week have substantiated the speculation of last week that the bottom of this market had been reached at 9½c. duty paid, for since last week's report a steady advance has taken place and sales of 500 to 1000 tons are reported. The price has advanced from 10 to 10½c. duty paid, last week to 13½ to 14c. this week and the demand is good.

ORES

Antimony: The market is exceedingly quiet, with the last reported sales at \$1.10 to \$1.20 per unit.

Tungsten: The foreign demand is active and considerable business has been done. The demand comes from France and Russia, and it is reported that these countries have bought nearly 500 tons. Some sales of concentrate have been made at \$17 to \$19 per unit. Stocks, while still of fair size, are probably reduced 50% at New York and Pittsburg. Great Britain is said to have purchased 80 tons of concentrate in the last few days. Ferro-tungsten has declined until it can be bought as low as \$2.75 per lb. of contained tungsten.

Industrial Notes

Information supplied by the manufacturers.

Portable Electric-Driven Air-Compressor

Compared with electric-driven coal-cutting machinery pneumatic equipment is cheaper in first cost; it is also safer. In order to present means of securing the fullest benefits of compressed-air machinery in electric-equipped mines, the Chicago Pneumatic Tool Co. has developed a portable, self-contained, electric-driven air-compressor, known as the 'Class N-SE Mine-Car.' In economy the unit compares favorably with a central compressor-plant on the surface. Its initial efficiency is of course not as high, due to its smaller capacity; but this difference is, in an appreciable degree, equalized by the losses resulting from leakage and drop of pressure in the pipe-line of the large plant; also, the portable compressor may be run close to the work so that the temperature of the air delivered to the drills, etc., is considerably increased. Feeder pipes are eliminated, often a considerable saving.

The compactness of this mine-car compressor is evident from the illustration. The unit consists of a horizontal,

PORTABLE ELECTRIC-DRIVEN AIR-COMPRESSOR.

straight-line, single cylinder air-compressor, driven by means of a motor through the medium of herring-bone gears. An air-receiver of proper size and a rheostat are provided. The entire apparatus is mounted upon a strong, but light, steel-car frame. The air-cylinder is fitted with the company's patented and efficient 'Simplate' inlet and discharge-valves. Necessary fly-wheel effect is secured through the rotation of the heavy gear. The positive splash system of lubrication is employed. Gears work in a bath of oil. Every part of this compressor unit is completely enclosed. Exposure to dampness will not injure it. Delicate or complicated features of construction have been avoided, and the machine is well suited to rough and heavy duty. It is so entirely automatic in action that it requires no attendant. The comparative lightness of the car permits of its removal from the rails when desired. The machines are made in six sizes, ranging in capacity from 51 to 311 cu. ft. of free air per minute at pressures of 80 to 100 lb. The larger sizes will take care of 6 to 8 and the smaller 1 or 2 'hummer' drills.

Commercial Paragraphs

The HAMMOND IRON WORKS of Warren, Pa., has arranged for representatives in Cuba, Central America, Brazil, Argentina, South America, and the British Colonies.

The UNITED NAVAL STORES Co. of 130 Pearl street, New

York, announces that it is ready to supply all the different fractions of pine and hard-wood distillates to mining companies, engineers, universities, etc., for research work. Several well-known institutions have already been given such oils.

In its instruction book No. 16, of 144 pages, the SMOOTH-ON MANUFACTURING Co. of Jersey City, N. J., tells all about Smooth-On iron cements, iron paints, corrugated iron gaskets. The cements are chemically prepared iron compounds sold in powdered form, and used by mixing with water to the consistency of putty. All manner of repairs may be effectively made by its use. We advise engineers to secure a copy of this useful work.

An interesting 9-page pamphlet entitled, 'Why Highly Oxidized Red Lead is Superior,' by G. W. Thompson, chief chemist of the NATIONAL LEAD CO., has been published by that concern. For centuries red lead, Pb_2O_3 , has been used in paints for the preservation of iron and steel. The percentage of true red lead in red lead varies from 70 to 100. Anything under 100% is considered a mixture of red lead and unconverted oxide of lead, litharge, from which red lead is made. Much progress has been recorded in the manufacture of red lead in the last 25 years. One is an increased percentage of true red lead, another is that red leads are finer from better grinding. Notes on painting, quantities used, and results are given.

Book Review

MAKING MONEY MAKE MONEY. By H. L. Barber. P. 315. A. J. Munson & Co., Chicago, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.50.

A unique book in its excessive use of capitals for emphasis. The author contends that men of limited means should put money into shares of newly-formed companies, rather than into bonds or savings banks, and thus have the chance of making from 100 to 1000% annually instead of the 3 to 5% of the conservative investor. He holds that men of limited means are deluded by our leading financiers, who conspire to get all of the money of the country into their own hands, and to this end subsidize the great newspapers and influential magazines to preach the false doctrine that shares are dangerous and bonds safe. The complaint of the author that a conspiracy exists to conceal the large profits paid by common shares seems ill-founded, in view of the 'Blue Sky' laws of many States, and the flood of circulars and advertisements issued by brokers and promoters. He finds that "innumerable opportunities" exist for money to earn from 100 to 1000% annually, and on page 31 shows that an annual investment of \$100 at 100% will amount to \$2,300 in 10 years (the correct amount is \$102,300); at the end of 15 years the investor will be a multi-millionaire. The reviewer feels that stopping at 15 years would be absurd, for by continuing for 31 years the total becomes over \$200,000,000,000, or more than the aggregate wealth of the United States. On page 221 is a "typical case" of capitalistic greed—the Western owner of a mineral deposit containing several hundred million dollars, on applying to capitalists for half a million dollars for development was asked to give up the whole property in exchange for the promise of a permanent superintendency at \$150 per month. The reviewer feels that this is a "typical" prospector's dream, and bears no relation to hard facts. The author gives instances of the great profits made by the fortunate buyer of common shares: in 19 years \$100 invested in Postum Cereal Co. grew to \$20,097; and Gillette's Safety Razor \$100 shares expanded to \$52,000. These and other profits are enough to lead many sanguine readers to follow the advice on to fortune, but prudent readers will be governed by the fear that they may be unlucky enough to buy in one of the companies that fail—and 95% of all companies are said to fail—and prefer to keep their money in bonds or savings banks.—W. H. S.

EDITORIAL

T. A. RICKARD, Editor

PIG-IRON production is recognized as a barometer of industry; that of the United States is increasing. Final figures for the first half of 1916 show a yield of 19,619,522 tons, compared with 12,233,791 tons in this period of 1915, and 17,682,422 tons in the second part of last year. Ferro-manganese made a gain from 0.43 to 0.51% of the total, and spiegeleisen 0.33 to 0.45%. The demand for steel from the warring nations shows no sign of abatement.

EVERY man is entitled to have his name spelled correctly, and the correct spelling is the way he spells it himself. How does the inventor of a famous roasting-furnace spell his name? The good people who use his furnace at Anaconda call it MacDougall, as shown in the excellent pamphlet recently issued; Mr. L. S. Austin makes it McDougal; Mr. T. T. Read spells it McDongall; while the A. I. M. E. volumes give both McDougall and MacDougall. Finally, the manufacturer of the furnace uses McDougall. We should like to hear from the gentleman himself, or his heirs and assigns, as the final authority on the matter.

METALLURGICAL results at the Ouro Preto gold mine in Brazil show careful work. The lode is a quartzose replacement in schist, the gold being associated intimately with arsenical pyrite. On ore averaging \$7.30 per ton the extraction is 91.41%, the total loss of metal from all sources being 60 cents per ton. Last year 85,400 tons was treated. At the sand-plant, the 63,206 tons leached averaged 88 cents per ton before treatment, of which 59 cents was recovered. Slime assayed 92 cents, giving a recovery of 80.6%. The combined cost of sand and slime treatment was only 23 cents per ton. These are excellent results from such low-grade material, with such a comparatively small tonnage, and are a credit to the superintendent, Mr. A. J. Bensusan, and his staff. Total costs amounted to \$6.10 per ton.

SHIPMENTS of copper from Chile and Peru to United States refineries continue to increase, due mainly to operations at Cerro de Pasco, Chuquibambata, and Braden. For the eleven months ended May 31, 1916, exports from these countries were 51,279,639 and 64,956,459 pounds, respectively, a total of 116,236,098, compared with 67,530,320 and 55,684,377 pounds for similar periods of the previous two years. Contemplated additions to these properties in the near future will augment the output considerably. The Chile Copper Company's yield in the first half of the current year was 19,724,385

pounds. In future this company will issue monthly statements. A new estimate of ore reserves places the total at 354,130,660 tons, averaging 2% copper. This is an increase of 50,000,000 tons since April 1915.

WE hope it is true that cotton-stalks can be used for making paper-pulp, as reported from Berlin, for the price of that commodity has risen uncomfortably. The use of thick paper for lining the trenches from the Channel to Switzerland is given as one cause, although paper wadding is no longer used in rifles. Imports of rags for paper manufacture have declined to nearly one-quarter what they were before the War. But the waste of paper in this country is reason enough for a scarcity. The bulky issues of a cheap and misinforming daily press indicate where the paper goes. An effort to reduce the number of pages has been made by several dailies in the East. As Thomas H. Price says in *Commerce and Finance*, "The average daily newspaper prints too much stuff. There is not enough attention given to editing. Condensation is not the art it used to be." This is true of the technical journals also. Quantity is attained at the expense of quality. The public is not critical and thinks it is getting more for its money when a paper is bulky and un-edited than when it is given matter that has been condensed and revised carefully.

GOLD output of the Rand in July was practically the same as in June, namely, 761,000 ounces. The current year will probably make a record. We have just received the annual report of the Transvaal Chamber of Mines covering the year 1915. It is less voluminous than the previous statement, but contains a number of interesting items. At the gold mines, an average of 22,081 whites and 193,687 Kaffirs were employed, earning £6,283,884 and £6,041,090 respectively. There were 5675 machine-drills operated. The crushing of 28,314,579 tons of ore, averaging \$6.30 per ton, was accomplished by 9990 stamps and 321 tube-mills. The working cost averaged \$4.18 per ton. The total yield was £37,264,992, equal to 40.1% of the world's total gold production in 1915. Dividends amounting to £7,619,416 were distributed. The Transvaal also produced 5,202,805 tons of coal, and diamonds worth £128,067, this small amount being due to the fact that the Premier mine was closed. Incidentally we note in a consular report from Johannesburg that a new diamond field has been discovered six miles from the Premier, but the extent of it is not yet known. Copper ore valued at £108,667 was also produced, and tin ore worth £337,188. Taxes totaled £1,877,452. A committee for the Chamber has completed

four dust-sampling surveys of the mines, a work of great utility. The staff is to be increased, so that every mine may be sampled once every two months. Stores purchased by all companies amounted to £10,889,115. At Johannesburg, on June 8, a conference of the councils of nine South African technical societies was held to start a movement for the furtherance of scientific research in the Union. As these are all live institutions, some good results may be expected.

NEW capital to the amount of £1,978,986,200 has been issued in London since the War began. Mining, financial, and commercial enterprises have suffered a great slump; of the total amount of new capital issued for all enterprises, only £102,694,300 was invested in this direction. Increases in the capitalization of existing companies amount to £95,828,700, which leaves little for fresh enterprise. Mining seems to have been the chief sufferer. During the period of peace from August 1913 to August 1914, £5,733,200 was invested in mining enterprises. This amount has dwindled to £1,841,800 during the first, and £516,500 in the second year of the War. The flow of English capital to foreign countries for the development of mines has practically stopped. The United States seems to have become, at least temporarily, the banker for the nations. Foreign loans and credits made in the United States since the War total \$1,764,950,000. This includes the new War loan of \$250,000,000 to England, while \$1,115,000,000 represents the total loans to Canada, England, France, and Russia, all for War purposes. In the meantime, our friends in South America have not been neglected, Argentine having received \$68,500,000, Chile \$6,000,000, and Bolivia \$1,000,000.

MINING in the Coeur d'Alene cannot boast the nearly three score and ten years of the Californian gold mines, nor the nearly 50 years of operation of its chief competitor, the lead district of south-eastern Missouri. Compared with copper-mining in Michigan or silver-mining in Nevada, the great mineral region in the panhandle of Idaho is only in its youth. Mining of placer gold in the Coeur d'Alene was begun in 1882 by A. J. Priehard, and the lead-silver deposits were staked several years later. "Thirty years ago," says Mr. William Wagner of Wallace in his new handbook on the Coeur d'Alene, "the district was uninhabited except for a few daring prospectors, and the Indians, who came to hunt and fish." Mr. Wagner continues, "nowhere can be found a mining district more favored by nature. There is an abundance of fresh water; the hills are well timbered, supplying cheap lumber; electric-power lines are built and railroads have been extended to the big mines." During 1915 the Consolidated Interstate-Callahan, a zinc mine, made the greatest profit in the Coeur d'Alene, \$2,921,487. The Bunker Hill & Sullivan won a profit of \$1,145,851, and the three companies under the same management, the Caledonia, the Ontario, and the Sierra Nevada, made profits of \$761,797 and \$223,724, and \$46,-

354, respectively. The Federal Mining & Smelting Company, which is a subsidiary of the American Smelting & Refining Company, made \$571,560 from its Morning mine, besides smaller amounts from the Last Chance and Standard properties, while its Frisco and Iron Mountain mines made no profit. The Greenhill-Cleveland Mining Company, controlled by the Federal company, cleared the sum of \$497,864. The Hercules Mining Company and the Tamarack & Custer, which are controlled by the Day family, made profits of \$1,096,019 and \$346,796 respectively. The Success Mining Company, also owned in the North-West, won \$898,935 in profit. The Hecla and Stewart companies made nearly identical winnings, \$593,680 and \$572,231 respectively. The Gold Hunter Company made a small gain, and a dozen other operators shipped ore without financial advantage.

ELECTROLYTIC zinc will be an Australian product in the near future. We learn by mail that the Amalgamated Zinc (De Baxay's) Company has contracted with the government of Tasmania (the island State) for a supply of electric power, the first unit of 4000 horse-power to be available by January 1918, or earlier if desired. It will be remembered that the Amalgamated Zinc operates at Broken Hill, in New South Wales, buying zinc-lead-silver tailing from the mining companies, treating it by flotation (at the rate of over 40,000 tons per month in normal times), and making a concentrate containing 49% zinc. Since the War began, this company has had some difficulty in disposing of its product, much of which came to American smelters. It is the desire of Australians to treat their output of ore and concentrate within the Commonwealth. As the Tasmanian government has recently acquired a hydro-electric plant capable of considerable expansion, permitting low rates for current, and as electrolytic zinc production is a success in the United States, the Amalgamated Zinc no doubt felt that it could go ahead and treat its concentrate by this method. This company's general manager, Mr. H. W. Gepp, has investigated practice in this country. The Electrolytic Zinc Company of Australasia has recently been organized with a capital of £1,000,000, backed by Amalgamated Zinc, for the production of electrolytic metal. While on this subject it may be said that in the west coast region of Tasmania there are several mines containing refractory ores. A smelter operated at Zeehan for a time, but unprofitably. A good deal of ore was sent to Europe for treatment. Recently the Mount Lyell company completed its option on the Mount Read and Roschery mines, which are estimated to contain 800,000 tons of ore averaging 29% zinc, 7.5% lead, and 9.5 oz. silver, and \$2.50 gold per ton. It is probable that, in addition to concentration of this ore, electrolytic treatment of the concentrate will follow. The Mount Lyell company has installed hydro-electric power-plants near its own copper mines at Queenstown, dispensing with steam. Tasmania is capable of large development in water-power, and is destined to become the laboratory of Australasia.

The Lid Unlocked

The weakness of the Government has been betrayed so that all the world may see. Any minority, any class or group of men, fixed in their determinations as we know trade-unions to be, can work its will. The railroad engineers and trainmen are too intelligent a class to wish to expose the country to the peril of dominance by the great hordes that are ever ready for the plunge into anarchy, but they have betrayed the fatal secret. The pious pacifists have had their way, and the nation of a 100 millions has an army such as was deemed necessary when we numbered 20 millions. We were going to have our way by force of moral suasion. That has just been subjected to trial, and we see that might rules, as usual. We have had to recognize that the ultimate police force of the country is insufficient to compel the settlement of industrial disputes within their proper sphere. Four hundred thousand men, through their four spokesmen at Washington, command the representatives of 100 million people, and are obeyed. An ultimatum is hurled; a narrow time limit set; and the dignity of the nation is humbled to comply with the mandate.

No regret need be felt that the railroad men are to have an 8-hour day without reduction of wage. It is to be supposed that the public can afford to pay the bill. It will mean such a vanishing fraction of a mill per ton-mile of freight moved that the only serious evil that might flow from it would be the excuse it might give to merchants for raising prices out of due proportion to the actual increased cost. We do not grudge the laboring man his just reward; our regret is that the discovery should have been made that neither he, nor you, nor we can count so hopefully as we did upon the future security of our Government with its guarantees of life, liberty, and equality of right to seek and enjoy the fruits of the earth.

The decision of the railroad engineers and trainmen to call a strike was pregnant with evil. Equally may it be said that the refusal of the railroad managers to accept the 8-hour day as a basis for negotiation of the other points at issue was an act of folly. They have added to the indignity put upon the country. They acted more like a company of poker players than a body of far-seeing business men; they tried to win by a bold game of bluff, when all the world could plainly see that their opponents held the better cards. Both sides were guilty of trifling with that most sensitive of all explosives, the passion of the multitude. It is not necessary to reach a firm conclusion as to the merits of the case in dispute to be able to brand the entire performance as dangerous to the welfare of the country.

If the crisis presented by the action of the railway brotherhoods shall awaken the American people to the need of preparedness to meet the emergencies of the Republic in both civil and military spheres, it will have served a most useful purpose. The spectacle of the President of the United States working day and night to prevent an industrial strike, and of Congress con-

verting itself with feverish precipitation into a mere machine for legalizing the demands of the representatives of labor-unions, is not edifying, nor does it augur well for the future stability of industry and national development. It makes patent the indifference that Congress has displayed toward the great needs of the day. It provokes wonder as to what new dilemma may arise, unforeseen and unprovided for, where the whip of circumstances may be used to force hasty adjustments, which the nation may repent at leisure. Without expressing an opinion as to which side in this controversy possesses the larger measure of right, any citizen who believes in his country must feel pained at what has happened. The thing to which we cannot close our eyes is that the brotherhoods brought forward their demands at a moment when the pieces were so set on the national chessboard that refusal was impossible. This indicates, what so many have long feared, that the physical inability of our Government to maintain law and order has been measured with exactitude by the masses. England, because of military weakness prior to the European war, which has given a new direction to English thought and feeling, was dragged again and again to the verge of social revolution. Many able students of politics and sociology had pointed out that a foreign war would prove her speediest cure for the social ferment imperiling the existence of the Empire. We have witnessed the fruit of unpreparedness in Mexico, where a petty revolution headed by Madero, after capturing nothing more than a single port of entry two thousand miles from the capital, revealed to the people the impotence of the government, so that soon the flames of anarchy were sweeping the country and destroying the institutions built under the constructive statesmanship of Diaz. No doubt the virtue had been allowed to rot out of some of those institutions; no doubt reforms were needed; yet is it also true that the structure reared by Diaz had in it more hope for the future of all Mexico, for poor and aristocrat, than can be found in the ashes that remain after the social conflagration. Madero playing Pandora found the lid unlocked and pried it open; never since have the sprites of evil suffered it to be shut.

Is our political strong-box also unlocked, and is the power wanting to hold in check the unthinking spirits that would sacrifice the treasure of our institutions for the sake of fleeting revel in the debaucheries of political license, so bitterly seen in the excesses of the French Revolution? It is evident that the railroad brotherhoods found at least one chest with the lock off. Not only is our army pitifully inadequate to insure respect for the laws, but almost the whole of that army had been dispatched to guard the 1700 miles of our southern boundary. Interruption of traffic for a few days would reduce these forces to destitution and practical helplessness. In such a situation the chances of renewed difficulties with Mexico would have been intensified. The folly of concentrating nearly our entire military strength on the border, and the certainty that it would

give rise to strikes, was pointed out in many quarters at the time. The action of the railroad brotherhoods has justified the warning then sounded.

That the brotherhoods took advantage of the situation is not cause for condemning them. They did what business men are daily doing in the smaller affairs of individual commercial warfare. They have merely discovered the opportunity for successfully forcing the hands of those with whom they were dealing. The declaration in the strike-order against the use of violence counts for nothing. No body of men could hope to win in such an industrial battle by merely quitting work and permitting others to be substituted in their places. Coercion is an essential part of these industrial protests. A government that was prepared to restrain the strikers from committing excesses through riot and arson could stand by and suffer the parties in interest to come to their own conclusions, while at the same time protecting the general welfare and rights of the public. Instead of that, the whole Administration and both houses of Congress are thrown into a panic, and half-baked legislation is turned out over-night to grant the 8-hour day, with provisions to protect in some measure the rights of the railroads and the general public, all of which may be upset by the Supreme Court, provoking new issues as perilous as those that for the moment were averted.

This same Congress, that has just been passing a niggardly appropriation for an utterly inadequate increase of the Army, is now compelled to put on a subservient Chinese grin at the behest of the calmly confident chiefs of the brotherhoods, and do their bidding! It may be better than to let the social pot boil over; the sympathetic strikes that would have accompanied the railroad walk-out might easily have let loose the barbarian element in society, imperiling the very foundations of the Republic. We may not forget what happened not many years ago at the Bunker Hill & Sullivan in Idaho, nor the social war and terrorism in Colorado, nor the display of the ugly side of human nature in the Pennsylvania coal strikes, nor the brutalities that suddenly thrust themselves above the erstwhile peaceful surface at Youngstown, Paterson, Lawrence, and Homestead.

The American people should learn from this lesson, and consider well the amelioration of industry by appropriate enabling legislation while there is time to work out the equities of the social problems involved, and meanwhile create a strong arm to insure order and respect for law in every emergency in order to prevent the destruction of those institutions under which men have found freedom and opportunity for generations. Imperfect many of these institutions may be, but they have been winnowed from the experiments and conscientious efforts of men who have mostly been true patriots, and who have shown superior genius for developing a sane and wholesome democratic government. These institutions may not be lightly endangered, for they represent the fruit of rational evolution. When the lid is off it is not the people that rules, it is not the national con-

science that dictates, but the passions of an unscrupulous minority. Neither is it when the lid is off that the poor obtain justice and opportunity. Behold Mexico, if anyone doubt! Consider, moreover, that two small minorities, so unlike in character and traditions that they could no more mix than can oil and water, are the ones that clamor against military preparedness—the pious fanatics called ‘pacifists,’ and the socialistic brotherhoods.

Cyanidation of Silver Ore

At Rochester, Nevada, the latest developed silver-gold district in that State, there are two cyanide mills in operation. In our issue of August 28, 1915, the plant of the Rochester Mines company was described by Mr. G. W. Wood; in the present issue that of the Nevada Packard Mines company is described by Mr. Herbert G. Thomson. The Rochester mill is a typical equipment of the continuous counter-current decantation system, known briefly as C. C. D. Thickeners are used exclusively without a filter. The ore is crushed in solution by heavy stamps, and is finally reduced in tube-mills so that 94% passes a 200-mesh screen. Following this, the pulp is agitated, thickened, and decanted in a series of vats. As custom ore is treated, no figures of cost are available for this 120-ton mill, which is being duplicated.

The Nevada Packard 100-ton mill was erected in 1915 at a cost of \$65,452, compared with the estimate of \$65,740 made by the designer, Mr. Knud Freitag. The ore is described as highly-altered sericitized rhyolite, of varying hardness, traversed by quartz veinlets. Cerargyrite, the chloride of silver, is the valuable constituent. The content ratio of gold to silver is 1:300. After being crushed to 1½-inch size the ore is further reduced to ¾ inch by rolls. Fine-grinding, so that 83.3% passes 200-mesh, is done by successive reduction in two short tube-mills, working in closed circuit, with a duplex classifier. This scheme has proved entirely satisfactory. The first contact of the ore with cyanide solution is at the No. 1 tube-mill feed-box. Selected lumps of rhyolite have largely replaced Danish pebbles, to the gain of efficiency and economy. The spiral pumps used are considered superior to bucket-elevators or air-lifts. From the thickeners the pulp goes to agitators, where most of the cyanide and lead acetate are added. Interesting data were secured on the use of lead salts. From the agitators the pulp flows to thickeners, it is then diluted with barren solution, and partly treated by the C. C. D. system. The underflow from the thickeners is finally dewatered on a filter of the revolving-drum type. The soluble loss per ton treated is 5 cents, an excellent result due to counter-current wash and the heavy water-wash on the filter. The total cost of treatment is \$1.26 per ton, and the recovery is 94.9%. A comparison of crushing and treatment at the two plants at Rochester shows considerable differences. The variation from Tonopah practice is also noteworthy. Mr. Thomson gives some useful hints on building construction and cost of installation.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Modern Blasting Practice

The Editor:

Sir—The benefits of careful tamping (or stemming) have been so fully brought out in the paper* by Walter O. Snelling and Clarence Hall, and emphasized by E. A. Collins† and P. B. McDonald‡ that there seems little reason for its not being more generally adopted. The present high price of explosives offers a special inducement

with hard ammonia powder is little, if any, more difficult than where soft gelatin powder is used. It has been noted that the chief difficulty in introducing the practice of tamping is the lack of suitable material furnished in convenient form to the men who load the holes. If the tamping material is furnished in specially marked cartridges, which are as easily loaded as a stick of powder, there is little difficulty in getting it used.

The tamping-bags, now being furnished at small cost

ment to reduce the quantity of explosives used and at the same time to substitute, where possible, cheaper grades having approximately the same strength as the corresponding gelatin powders.

The conclusion drawn from the tests made by the U. S. Bureau of Mines, that both these economies can be effected by careful stemming, have been verified in the practice at Mogollon. With plenty of suitable tamping material on hand the loading of back holes, in stoping,

by some powder companies, have undoubtedly tended to increase the practice of tamping. However, the filling of the bags by hand is slow and unsatisfactory. To overcome this we have introduced at Mogollon a simple machine for filling the bags, which is outlined in the accompanying drawing. The empty bags are slipped over the spouts on the end of the machine and the movement of the spiral forces the material into the bags, causing them to slip off from the spouts as they fill. A tight and loose pulley and belt-shifter add to the convenience in operating. That such a machine can be improvised at almost any mine is indicated by the fact that the one

*Technical Paper 17, U. S. Bureau of Mines.

†'Efficiency of Tamping,' M. & S. P., May 22, 1915.

‡'Modern Blasting Practice,' M. & S. P., May 27, 1916.

shown was built, under the direction of D. L. Perkins, mill superintendent, mostly from material recovered from the scrap-pile.

At the Last Chance mine of the Mogollon Mines Co. the factors affecting the amount of ore broken in stoping are the width of the vein and the character of the vein filling. In the wider stopes, up to 14 and 18 ft. wide, there is a large amount of calcite present, permitting deep holes to be drilled, while in the stopes 5 to 10 ft. wide the relative amount of calcite is usually less and the silicification greater. Between these extremes the ore broken in stoping varies from 16 to 8 tons per drill-shift, or from 1 to $\frac{1}{2}$ tons per lb. of powder. In any stope where conditions have remained the same there has been no decrease in the quantity of ore broken per drill-shift when tamping material has been substituted for the last stick of powder in loading holes. The number of tons of ore broken per pound of powder has shown a proportionate increase, and the cost of explosives per ton a corresponding decrease.

S. J. KIDDER.

Mogollon, New Mexico, August 21.

[The high price of dynamite as a consequence of the War has caused many mining companies to experiment with lower-grade explosive but using stronger detonators, thus substituting say 40% powder for 60%. Results have been successful.—Editor.]

A Traveler's Library

The Editor:

Sir—In the August 12 issue 'Subscriber' wishes to solve a problem that has worried every conscientious engineer who has traveled extensively. Personally I have found a filing method based on Carl A. Allen's admirable extension of the Dewey indexing system to be of great value, and have used it as the most suitable receptacle for all of my notes and many text-books which I have unbound and distributed through the files. Therefore, knowing where I am going and the general nature of the work to be done, I can take as many envelopes (11 by 14 in. fibre) as I find necessary to cover the work in hand. Later, if I find that I need more data, I have only to write to the office for the required envelopes, giving their numbers, and so get them in a reasonably short time.

In conjunction with the files I suggest the following books:

Hütte's 'Das Ingenieurs Taschenbuch,' 3 volumes, with Flügel's dictionary English-German and German-English; Hoover's 'Principles of Mining;' Finlay's 'Cost of Mining;' Gillette's 'Cost Data;' American Institute of Mining Engineers index to all volumes; a good book on therapeutics and Materia Medica, and a good book on theory and practice of technical writing, followed by a choice of the following subjects: surveying, assaying, metallurgy, chemistry, geology, mineralogy, prospecting, and sampling.

This will make 17 volumes in all, besides the file en-

velopes, all of which may be packed with room to spare for the card index in a box 11 $\frac{1}{2}$ in. wide by 14 $\frac{1}{2}$ in. deep by 30 in. long (all inside measurements). Such a box made of $\frac{3}{4}$ -in. ash or oak, with dove-tailed corners, a hinged cover, and padlock, will last from 6 to 8 years, and can be made water-tight by including two thicknesses of heavy canton flannel between all joints and the application of new electrician's tape around the joints of the cover from time to time.

In addition to this, an engineer should remember the service of the A. I. M. E. Library Bureau.

JOHN B. STEWART.

Waxhaw, North Carolina, August 17.

Prospecting

The Editor:

Sir—I quite agree with Mr. Platt's article in the August 12 issue as to the absurdity of Mr. French's assumptions. Mr. French is unjust to the prospector. While not disparaging the value of an engineer's services, I would sooner pay a good prospector \$250 per month and the engineer \$90 while looking, or prospecting, for a mineral deposit. My long experience in this work makes me feel that way. After a mine is opened, with considerable ore, I would employ an engineer to examine it, make assay-plans, etc., and advise on a treatment process. Mr. French rewards two prospectors with \$1000 if they find a rich mine, while the engineer, who probably could never find one, is to receive shares in the company. Mr. French does not know the real old-time prospector, or he would not talk in this manner. Since large mining companies will buy only properties showing a certain amount of ore—and they are right in this—I would suggest that a small company be organized to lease and bond one or more promising prospects, of which there are many owned by prospectors, who have done a good deal of work on them. With \$5000 judiciously spent, not in high salaries for engineers, probably a good mine would be opened without having to spend time and money searching for it first. Given \$5000 I could do this now.

M. F. GRAUPNER.

Butte, Montana, August 16.

TUNGSTEN in Japan is worth \$1300 per ton for 65% product, or \$20 per unit. In seven months, shipments to the United States total over 400 tons. The monthly output of Japanese and Korean mines is about 150 tons. At Rollinsville, Colorado, the Rare Metals Ore Co. is paying the following for tungsten ore: 1% ore, \$2 per ton; 1 $\frac{1}{2}$, \$1.50; 1 $\frac{3}{4}$, \$6; 1 $\frac{1}{2}$, \$7.50; 2, \$10.50; 3, \$25; 4, \$35; 5, \$45; 6, \$55; 7, \$65; 8, \$75; 9, \$85; 10, \$95; 15, \$150; 20, \$200; 25, \$250; and 30%, \$300 per ton. The tungsten situation at Boulder is brighter, according to Eugene Stevens, of the Rogers mines, who recently sold a lot for \$20 per unit. It is reported that users of tungsten will not make any time contracts, and will not order ahead for 30 days.

THE NEVADA-PACKARD MILL.

Construction and Operation of the Nevada Packard Mill

By Herbert G. Thomson

INTRODUCTORY. The cyanide plant of the Nevada Packard Mines Co. is situated at Packard, in Humboldt county, Nevada, four miles from Rochester and nine from Oreana, the nearest Southern Pacific railroad point. The Nevada Short Line narrow-gauge railroad runs within four miles of the property, but the combined rail and wagon transportation charges for supplies from Oreana are the same as the all-wagon haulage-rate from that point, \$8.75 per ton.

The ore is a remarkable one. It is essentially a highly altered sericitized rhyolite, varying from a soft and friable talcose or schistose product to an extremely tough silicified variety. The rhyolite is traversed by occasional stringers of quartz. Cerargyrite is the valuable constituent of the ore. Sulphides occur sparingly, while sulph-antimonates or arsenates are extremely rare. The ratio of gold to silver is about 1:300. In places small quartz veinlets carry a much higher proportion of gold, giving a string of colors when panned. Preliminary tests showed the ore to be easily amenable to cyanidation. Briefly, the process consists of crushing dry in rolls, grinding in tube-mills, agitation, and modified counter-current decantation followed by filtration.

CONSTRUCTION. The mill was designed and erected by Knud Freitag, who remained as superintendent for several months after the completion of the plant. The mill is directly below the portal of the lowest adit. In order to allow sufficient room at the bottom for the disposal of

tailings, it was necessary to house the tube-mills in an addition at the side of the main building. The slope of the mill-site is about 15°, allowing most of the pulp-transference to be done by gravity. The crushing-plant is situated 80 ft. from the mill. Construction of the mill started on August 12, 1915, at which time three-quarters of the excavation work was completed. Operations began on December 4, 1915. The usual 'timing-up' process was conspicuous by its absence. In excavating for foundations, 5200 tons of material was removed, a large part being hard rhyolite, so that 1000 pounds of dynamite had to be used. All foundations are of concrete. The main building is 64 ft. wide by 144 ft. long. The tube-mill addition is 40 by 42 ft., and the crushing-plant 24 by 32 ft. In all, 220,000 ft. B.M. of lumber was used in the mill-construction. Oregon pine was used for the framing, while the roof and sides were built of 1-inch fir boards covered with J. M. asbestos roofing. The Oregon pine was furnished by the C. F. Smith Lumber Co., the siding, roof, and flooring by the Red River Lumber Co., and the heavy timbers for the crushing-plant by the Sierra Nevada Wood & Lumber Co. The asbestos covering has proved an excellent non-conductor of heat. With a temperature ranging from 10° below to 110° above zero, this becomes an important feature.

The entire mill-frame presents a neat and finished appearance, and the observer is highly impressed with the clean-cut and workmanlike manner in which attention

has been given to every detail of the construction. Due consideration has been given to the proper design of all members of the structure, without the use of an excess of material. There is a notable absence of useless or over-size timbers, without loss of the necessary strength and rigidity. Another feature is the use of butt-joints and corbel (Fig. 1) for joining stringers, instead of the usual splice-joint (Fig. 2). The use of this joint means a saving in labor, both in framing and erecting. The splice-joint, of course, is used in all trusses. The thickener and agitator mechanisms are suspended from the trusses, as well as the transmission machinery. Good clearances have been provided around all machinery and tanks, and every part is easily accessible. Floors are constructed around all tanks. Runways are built around and alongside all the mechanical appliances. Belts and transmission parts are overhead and well guarded in ac-

Fig. 2.

DETAILS OF BUTT AND SPLICE-JOINTS IN BUILDING.

cordance with safety-first ideas. Circular steel ore-bins furnished by the Western Pipe & Steel Co. were used instead of the ordinary wooden bins. The first cost of this type is about half of that of wooden bins of the same capacity. The entire equipment was selected with one object in view: to obtain the highest metallurgical as well as mechanical efficiency. All purchases were made from manufacturers of high-grade material on competitive bids based on complete detailed specifications submitted by the constructing engineer. No material was purchased because it was "good enough" or cheap, as experience has proved that this manner of selection means grief for the operators.

The selection of high-grade machinery does not necessarily mean high first cost of mill, as has been shown at Packard. However, it does mean low costs of operation and maintenance.

The original estimate furnished by Mr. Freitag called for \$65,740. The final cost of the completed mill was \$65,451.94 divided as follows:

Equipment (machinery, supplies, etc.)	\$38,765.34
Grading (material, labor and teams)	4,213.05
Concrete (material and labor)	1,738.48
Framing (material and labor)	10,096.57
Construction (material and labor)	9,093.50
Engineering	1,545.00
Total	\$65,451.94

As carefully segregated costs were not kept until the actual construction work began, more detailed figures are

not available. However, the complete labor costs, exclusive of teaming, grading, and excavating, which work, as previously mentioned, was nearly completed when the erection of the mill started, may be of interest.

OPERATION. From the mine, the ore is trammed in one-ton Matteson cars to the crushing-plant, where it is weighed on a Fairbanks recording-beam scale, and dumped into one of two circular steel ore-bins, having a combined capacity of 100 tons. Lime is added at this point, usually one shovelful to every four cars being sufficient to maintain the desired alkalinity. The steel bins are each 12 ft. diam. by 16 ft. deep, constructed in four courses, with $2\frac{1}{2}$ by $2\frac{1}{2}$ by $\frac{3}{8}$ angle-iron reinforcements at top and bottom. The two lower sections are of $\frac{1}{4}$ -inch steel, and the upper two of $\frac{3}{8}$ -inch. As far as the rigidity of the bins is concerned, $\frac{3}{8}$ -in. steel would have been sufficient for all four courses, but $\frac{1}{4}$ -in. was used on the lower two so as to withstand abrasion from the coarse ore. These bins have proved satisfactory, especially to

the mill-men, who are relieved of all ore-bin shoveling. The ore is drawn out through two standard 18 by 24-in. steel-plate rack-and-pinion ore-bin gates passing over two 20 by 45-in. grizzlies spaced $1\frac{1}{2}$ inches and set on a 45° slope. The fine passes to the bucket-elevator and the coarse is fed to a No. 5 Superior McCully gyratory crusher set to $1\frac{1}{2}$ inch. The crushed product is elevated in the 14-in. belt-and-bucket elevator to a 9-ft. by 30-in. trommel, constructed of No. 10 wire, 2 mesh, having $\frac{3}{4}$ -in. openings and making 20 r.p.m. The wear on these screens is heavy, the life of each being only about two months. The oversize passes to a set of $37\frac{1}{2}$ by 15-in. Garfield rolls, and the undersize to the mill conveyor-belt. The rolls are set to $\frac{3}{4}$ -in. and readily handle the tough ore as well as an occasional drill-steel. Automatic feeding devices are not used, but in spite of the comparatively coarse feed, the roll-shells have not corrugated to any appreciable extent after seven months' run. The shells are of chrome-steel. The discharge from the rolls is returned by the elevator to the trommel for re-sizing. The trommel, elevator, and chutes are enclosed in a light, removable, dust-proof housing lined with sheet-iron. The conveyor is troughed and equipped with 14-in. Maxeon belt. It is 70.5 ft. centre to centre of

pulleys, inclined at an angle of 18° , and running at a speed of 300 ft. per minute.

The crusher, rolls, trommel, and elevator are driven by a 60-hp. Westinghouse induction-motor. This motor, as well as all others in the mill, is equipped with automatic overload-relay and no-voltage release. Goodrich Pinnacle rubber belting is used for driving the rolls and crusher and is giving good service. The belt-conveyor discharges the ore into a 15 by 28 ft. 100-ton steel bin, similar in construction to those in the crusher plant. Head grab-samples are taken from the ascending stream of ore. These have checked fairly well with smelter-returns, but an automatic dip-sampler will soon be installed.

The grinding department in the Packard mill differs radically from standard practice by the introduction of stage-grinding in short tube-mills. The grinding is done in two short-length Power & Mining Machinery Co. tube-mills in closed circuit with a Dorr duplex classifier. The designer of the mill is an advocate of short-length tube-mills, and the work they do has borne out his contentions regarding their efficiency. In spite of the presence of some soft ore, there is enough of the extremely tough silicified rhyolite to give a run-of-mine ore similar

THIS PICTURE IS FULL OF INTEREST TO THE METALLURGICAL ENGINEER, SHOWING MOTOR AND CHAIN-DRIVEN SHORT TUBE MILLS IN CLOSED-CIRCUIT WITH A CLASSIFIER.

to that of the average Californian Mother Lode mine.

Through a bin-gate the ore is drawn onto a 2 by 6-ft. Link-Belt steel apron-feeder, and discharged into the No. 1 tube-mill feed-box. This is, I believe, the first time that an apron-feeder has been used for this purpose in a cyanide plant. It has proved a thorough success. The regularity of the feed and the ease with which it can be adjusted are attractive features of the apron-feeder. The quantity of material fed to the tubes is regulated either by the speed of the feeder, controlled by an adjustable eccentric or by the amount that the ore-bin gate is opened. When once set, it needs no further attention.

In No. 1 tube-mill box the ore first comes in contact with the cyanide solution. Sufficient solution from the stock-tank is added to bring the moisture content up to 40%. The first tube-mill is six feet in diameter by five feet in length. At the discharge end, sufficient stock-solution for proper classification is added; and the pulp flows by gravity to the feed-box of the classifier. This machine does its usual excellent work. The classifier-discharge is transferred to the second tube-mill, 6 ft. diam. by 10 ft. long, by a 10 ft. by 8 in. screw-conveyor, chain-driven from the classifier-shaft. Solution is again added to bring the moisture up to 40%. The tube-mill discharge is again returned to the classifier.

No. 1 mill was designed for use as a ball-mill, but in the first test made with siliceous pebbles it did such satisfactory work that the change to a ball-mill will soon be made. It is probable that Campbell & Kelly liners and balls manufactured at Tonopah will be used. They have proved satisfactory in the Tonopah and Manhattan mills. Both mills are at present lined with Forbes white-iron liners. These are similar to the El Oro. They are spaced so as to allow for the removal of single sections when worn, thus obtaining maximum life for each liner. An average life of about eight months is indicated. The mills were started with siliceous pebble-loads, but selected rhyolite has largely replaced the Danish pebbles. Although the rhyolite is tough and silicified, it still retains enough of its granular structure to 'sand' somewhat, and it is evident that the capacity of the mills would be reduced below 90 tons daily if rhyolite entirely were used. However, as the rhyolite 'pebbles' contain sufficient gold and silver to pay for all handling, the use of them has proved economical, especially during the present scarcity and high price of the siliceous. No account is kept of the quantity added, as the amount about compensates for the moisture contained in the ore, no reduction for which is made in computing tonnage. The discharge-screens are 4 ft. diam., made in two sections. Being strongly ribbed on the discharge side, the ribs act as lifters assisting in a rapid discharge. The use of reverse-screw discharges was considered, but the reduction of discharge-area and capacity consequent upon their use would more than outweigh any advantage. The main bearings are 16 by 16 in. The scoop-feeds are of special design, having removable plates on the outer faces, allowing inspection of the spirals. They are also fitted with white iron digging lips, bolted to the frames, taking the heaviest

wear from the scoops. These lips last about six months and are easily and cheaply replaceable. The mills are driven by a single 100-hp. Westinghouse slip-ring induction motor. For this motor, a rheostatic controller is used. The motor is connected to the tube-mill gear-shaft by silent chain-drives and Hll clutches. These clutches are rarely used, the mills starting from rest on slow speed. The following screen-tests show the work being done in the grinding department.

		No. 1 tube-mill			No. 2 tube-mill		Classi- fier
	Screen aperture,	Head- ing	dis- charge	Classi- fier dis- charge	dis- charge	over- flow	
	Mesh	In.	%	%			
+	4	0.185	33.9	0.2	0.2
+	10	0.065	21.7	0.9	2.5
+	20	0.034	9.8	2.3	3.9

Of the minus 200 classifier-overflow product, 5.2% is sand and 94.8% slime. These screen-tests are not ex-

Fig. 3.

FRENIER PUMP ARRANGEMENT.

ceptional, but the averages of all tests made, the majority of them having been made while the pebble-load consisted of about 50% each of rhyolite and siliceous. A short while ago it was noted that a heavy concentrate was collecting in the feed and discharge boxes of the tube-mills and classifier; after removing the iron with a magnet, an assay of the residue showed \$2300 gold and \$180 silver per ton. An examination of the coarser particles proved the presence of flakes of a coated gold-silver alloy. As has been previously observed in many Mexican cyanide-plants where tube-mills were used, the fragments of copper and brass from caps, wire, etc., were heavily plated with silver. Careful tests on the tailing showed

that the classifier acted as an effective barrier to the passage of this concentrate farther into the mill-circuit.

The classifier-overflow, diluted to about 7:1, is elevated by a No. 1 Abbé-Frenier spiral pump to No. 1 Dorr thickener. The lift is about 23 ft., and as the maximum height to which a Frenier will elevate this material is about 20 ft., an air connection was made to the riser. Merely 'cracking' the valve admits enough air, acting on the air-lift principle, to overcome the difference. When first installed, the pump showed a disconcerting tendency to slop over under slight provocation. By returning a portion of the pulp through a by-pass as shown in the accompanying sketch, this trouble was entirely remedied. I believe that everyone who has seen the work done here by the Frenier will agree that it is far superior

ing-tank in which sixteen 5 by 8-ft. Butters-type canvas leaves are suspended. The clear solution is drawn through these leaves by a 2-in. Gould rotary pump, and discharged into a 12 by 10-ft. pregnant solution-tank. This clarified solution is pumped through one of two 16-frame 36-in. Merrill precipitation-presses by a 5½ by 6 Deane triplex-plunger pump. The two presses are used alternately, clean-ups being made every 12 to 15 days. Single cloths of No. 10 canvas only are used, safely withstanding a pressure of 35 lb., which is reached just before a clean-up. The same cloths are used several times. From 5 to 6 tons of solution per ton of ore is precipitated. The standard Merrill zinc-dust screw-feeder and emulsifier are used. The zinc is added to the pregnant solution at the pump intake, and is in contact

PRECIPITATION-PRESSES AND MOTOR-DRIVEN COMPRESSOR.

to the bucket-elevator or straight air-lift. However, when the manufacturer's catalogue naively states that "it is impossible to have the wheel elevate all the liquid without having some of the liquid overflow at times and when starting and stopping, so that it is absolutely necessary to provide a sump to receive the overflow," the prospective user may be pardoned for maintaining the Missourian attitude.

The Dorr classifier, Frenier apron-feeder and screw-conveyor, as well as the crushing-plant conveyor-belt, are driven by a 10-hp. motor. Discharge from the Frenier flows into a 28 by 10-ft. Dorr thickener (No. 1). So far, no trouble has been experienced from foaming in any part of the thickeners. They are all equipped with the simplified type of lifters, and with electric-bell overload-alarms. The solution overflows to a 12 by 10-ft. clarify-

*Wherever assay-values are given in this article, they will be on the basis of 50-cent silver.

The pregnant solution entering the presses averages 1.6 KCN and 0.8 P. A. The effluent titrates 1.95 KCN and 0.7 P. A. A re-generation of 0.35 lb. KCN per ton on a 2-lb. solution is remarkable, but it has been repeatedly checked by different operators. The advantages of zinc-dust over shaving, except in smaller mills, have been too frequently mentioned to warrant repetition. The survival of the obsolete zinc-boxes shows tortoise tendencies.

The precipitate is dried to less than 14% moisture and shipped to the smelter. A refinery will be erected soon. A representative, though incomplete, analysis of the product follows:

	%		%
Ag	69.9	Al ₂ O ₃ + Fe ₂ O ₃	0.89
Au	0.022	Insoluble:	
Zn	15.50	Al ₂ O ₃	
CaCO ₃	3.35	SiO ₂ , etc. 1.61 }	2.03
CaO	0.82	Cu	trace
Na ₂ CO ₃	0.80	Pb	none

Returning to the mill-circuit: The underflow from No. 1 thickener, having a specific gravity of about 1.45, is discharged into the first of two Dorr agitators, each 28 by 16 ft., where it is diluted to a gravity of 1.3, with stock solution. Most of the cyanide and lead acetate are added in this agitator, the remainder being dissolved in the stock-tank. The cyanide strength is kept around 2 lb. KCN and the protective alkalinity at 0.8 lb. CaO per ton. Sodium cyanide in the 'cyan-egg' form is used, but following general custom, the silver nitrate solution is standardized to KCN. An analysis of the solution showed the following constituents:

	%		%
K ₂ Zn(CN) ₄	0.15	CaO	0.038*
NaCN (free)	0.07	Al ₂ (SO ₄) ₃	0.069
NaAg(CN) ₂	0.009	K ₂ Fe(CN) ₆	trace
SiO ₂	0.004		

*By analysis, 0.05 by P. A. determination.

Total solids at 110° = 0.359%.

Total cyanogen = 2.06 lb. per ton in terms of KCN.

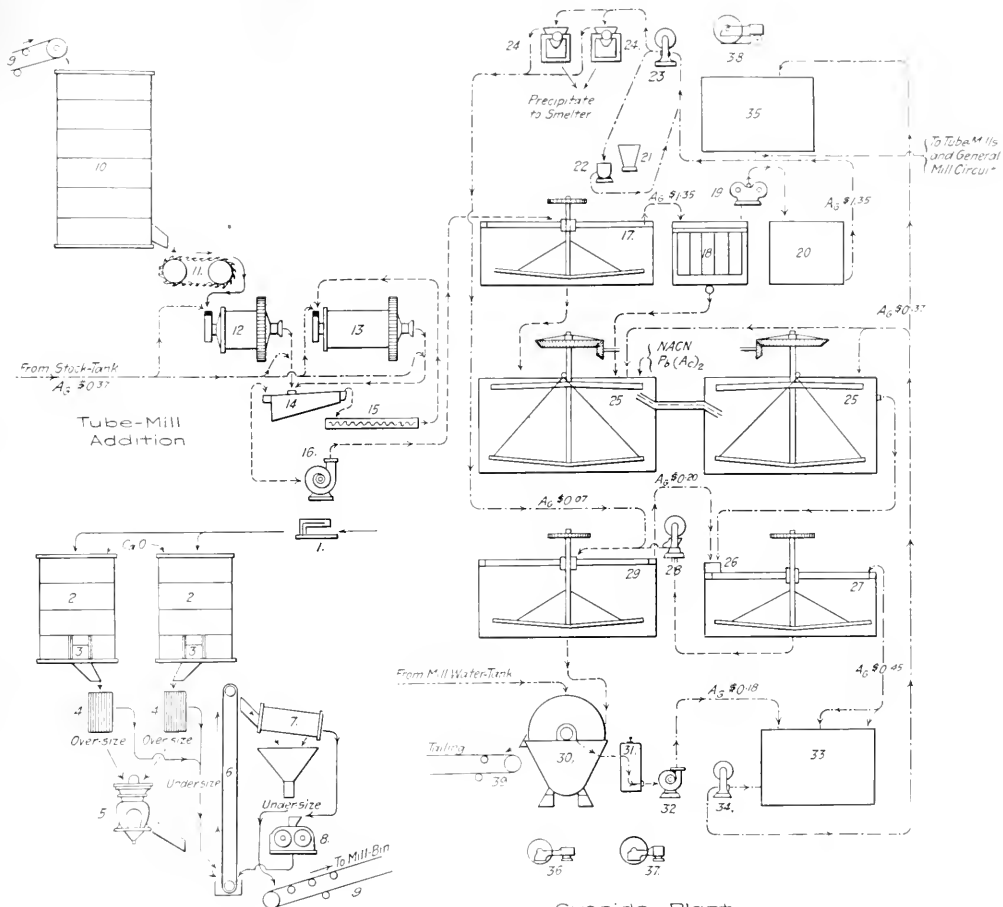

The reducing power of the solution is remarkably low, being equivalent to $\frac{1}{10}$ cc. N/10 KMnO₄ on a 10 cc. sample (with 2 cc. 1:1 H₂SO₄).

In the use of lead salts, we had the usual experience. Knowing that sulphides were practically absent, it was hoped that lead would not have to be used, though a supply was kept on hand. For the first three weeks the extraction remained near 95%, and then dropped gradually. Immediately upon the addition of lead acetate, the extraction returned to normal. Frequent tests with both nitro-prusside and lead carbonate have failed to show a trace of alkaline sulphides in any part of the mill-circuit. Ten pounds of lead acetate only are added daily.

The two agitators are connected in series by a straight pipe. The agitating mechanism is suspended from the roof-trusses. A unique feature is the use of one right and one left-hand drive. Besides the more symmetrical arrangement, there is a saving of one bent in the mill-framing. The air is—or was—admitted at the bottom of the tanks, through ball-check air-inlet valves. Soon

after beginning operations, one valve snapped off, and was found reposing in one of the launder-arms. The agitator worked as well as ever, so the valve was never replaced. The Dorr machines work well on low air-pressures, require practically no attention and little power. Although a development of the last few years, they have already sent many of the weird and wonderful devices that went by the name of agitators to the scrap-heap. The two agitators, thickener, zinc-dust feeder, triplex and rotary pumps are driven by a 10-hp. motor.

From the agitators the pulp flows by gravity to the feed-box of No. 2 Dorr thickener—the first of two counter-current decantation tanks. It is diluted in the box by the overflow from No. 3 thickener and flows down a staggered riffle mixing-launder to the feed-well of No. 2 thickener. The clear solution flows to the sump-tank. The discharge is transferred by a No. 4 Colorado Iron Works diaphragm pump to No. 3 thickener, where it is diluted with the barren solution discharged from the Merrill presses. No. 2 thickener is 28 ft. diam. by 1 ft. deep. No. 3 thickener has the same diameter but is 12 ft. deep, giving a fall of two feet between them for allowing the decanted solution to flow from the third to the second tank. The increase in the depth of this tank provides additional storage-room for pulp during shut-downs of the filter. The underflow, having a specific gravity of about 1.5, is discharged into an 11½ by 12-ft. Oliver filter. The vacuum is maintained at 22 in. by a 10 by 12 in. Doak dry-vacuum pump connected with a receiver fitted with the usual float-valve release. The pipe connecting the receiver and dry-vacuum pump is run to the upper mill-floor and back, giving an effective rise of nearly 50 ft. It is not always remembered in installing dry-vacuum pumps for filtration that the combined air-lift action and vacuum will raise the solution many feet above the theoretical 30, if the float valve fails to release. The solution is handled by a 2-in. Krogh centrifugal pump, discharging into the 20 by 12 ft. sump-tank. External air-lifts as well as mechanical agitators are used to keep the pulp from settling. The filter-canvas will have a probable life of 10 months. Water only is used for washing and is sprayed on both the ascending and descending sides by vermord sprays. It is interesting to note that giving the cake practically the limit of water-wash just holds the amount of solution constant in the mill-circuit. In many of the Californian mills, an all-water wash would make the 'wasting' of solution necessary in a very short time. The explanation of the difference lies, of course, in the low moisture-content of the ore treated and the excessive evaporation of mill-solution due to the dry atmosphere. The cake is discharged with a moisture-content of 21.4%. Daily determinations of the soluble loss were made for the period of one month, and averaged slightly over 5 cents per ton. This low loss is due to the reduction in value of the solution by counter-current wash in the thickeners and the heavy water-wash on the drum. All soluble-loss assays are made by determining the moisture-content of the sample, agitating thoroughly with a measured volume of water

and assaying the filtered solution. It need scarcely be remarked that the unwashed-minus-washed tailing method does not give accurate results. The cyanide loss in the tailing is under 0.2 lb. per ton. It is a safe prediction that the counter-current decantation method is going to play a large part in future cyanidation. It is an equally safe prediction, however, that except in the case of low-grade ore treated with low-content cyanide solutions, continuous vacuum-filtration will follow the decantation step in the process.

The following table gives the extraction throughout the mill:

	Assay-value	Cumulative extraction, %
Headings	\$7.06	...
Washed No. 1 tube-mill discharge	3.16	55.3
Washed classifier-discharge	3.31	53.1
Washed No. 2 tube-mill discharge	2.07	70.0
Washed classifier overflow	1.45	79.5
Washed No. 1 thickener discharge	1.38	80.4
Washed No. 2 agitator discharge	0.56	92.1
Washed No. 2 thickener discharge	0.49	93.0
Washed No. 3 thickener discharge (filter-feed)	0.46	93.5
Washed filter-tailing	0.28	94.6
Unwashed filter-tailing	0.44	93.8

The above are the averages of a number of assays run on consecutive days. The high extraction in the tube-mill circuit and the low extraction in the thickeners are interesting. The tailing is conveyed to the dump by a 12-in. Goodrich conveyor-belt, only sufficient water being added to keep the discharge-chute wet. A 5-hp. motor direct-g geared to the head pulley drives the tailing-conveyor. A 30-hp. motor furnishes power for driving the two lower thickeners, diaphragm-pump, Oliver filter, transfer-pump, air-compressor, and Deane triplex pump. The latter, equipped with the usual by-pass, returns the solution from the sump-tank to the stock-tank at the head of the mill.

The power-line of the Nevada Valleys Power Co. delivers the current to the transformers at 6600 volts, and is there stepped down to 440 volts for the motors, and to 120 volts for the lighting circuit. 250-watt nitrogen lamps are used for illuminating the tube-mill floor, and 60-watt tungsten-filament lamps elsewhere. In order to balance the power-load, the crusher and rolls are run on graveyard shift while the compressor at the mine is shut-down.

The entire crew in the mill consists of three solution-men, three solution-helpers, a repair-man and a roustabout. The solution-helpers run the crusher. As the mine-compressor is in the mill-building, and is looked after by the mill-crew, the time of one man daily is charged to mine-account. The wages paid are probably as high as any in Nevada.

Solution-men	\$5.00	Roustabout	\$4.00
Solution-helpers	1.50	Repair-man	5.00

The cost per ton milled, on a basis of 2736 tons per month (the average since starting) is \$1.265 per ton distributed as follows:

	Consumption per ton of ore milled, Lb.	Price per lb., Cents	Cost per ton, Cents	%
Cyanide	0.316	25	7.9	6.3
Lead acetate	0.118	13.7	1.7	1.4
Zinc	0.747	29	21.8	17.2
Pebbles (exclusive of mine-rock)	2.29	7.5	4.0	3.1
Hydrochloric acid	0.029	7.5	0.2	0.1
Lime	2.36	1.1	2.6	2.1
Power, 1,425 hp. at 26.5c. per hp.-day			38.0	29.9
Assaying (73% labor)			3.3	2.8
Miscellaneous chemicals			0.2	0.1
Labor			31.5	24.9
Supervision			2.9	2.3
Maintenance and repairs (90% labor)			3.9	3.0
Miscellaneous supplies			8.5	6.7
Total			\$1.265	100.0

The extraction, based on smelter-returns, has averaged 94.9% since the beginning of operations.

In conclusion, a few words may be added regarding what Gelasio Cactani has called "the psychology of milling." The mill is well lighted and arranged so that all parts are easily accessible. The company furnishes the unmarried men on shift-work with cabins, while the bunkhouses of the miners are divided into rooms, two men sharing a room. The boarding-house is run at cost, and high wages are paid. A total mining, milling, and development cost of a few cents over \$4 per ton, and an extraction of 95% of the precious metals in the ore strengthens the belief of the management that successful mining and low wages are not synonymous.

I am indebted to Mr. Freitag for many of the data given in this article, and also to J. W. Wilkey, superintendent, and B. B. Hall, accountant, of the Nevada Packard Mines Co. for aid given in its preparation.

THE TURN in the zinc market as a consequence of War conditions is indicated by the record of the Consolidated Interstate-Callahan mine in the Coeur d'Alene. Previous to the War, the company was losing money. For the year ended June 30, 1914, the operating loss was \$99,314. During the year ended June 30, 1915, this debt was paid, dividends of \$697,597 were distributed, and in addition there remained a surplus of \$1,094,862. A single dividend in August, 1915, was \$960,000, and the dividends during 1915 totaled \$2,530,000. During the first six months of 1916, the Interstate-Callahan paid dividends of \$1,394,970.

A TIN-CONCENTRATING AND SMELTING PLANT for the An-Yuan mines in Hunan province, southern China, is shortly to be placed in commission by the Wah Chang Mining & Smelting Co., which will offer this product for sale at New York and through agencies in Europe. These mines are in the Ichanghsien district, and contain both oxide and sulphide ores occurring as chimneys in limestone, marmorized by granite and intruded by a later granite dike along the course of which the ore-chimneys are found.

Mining and Milling in Arkansas

By L. L. Wittich

*Zinc and lead ores shipped from northern Arkansas mines aggregate 80 to 100 carloads per month. About 85% of this is zinc carbonate, 5% sphalerite and 5% lead, chiefly galena. At no time has the output been so heavy; at no time has activity in mill construction been so pronounced. The influx to Arkansas fields is due to the high price of zinc ore, and the steady development of the mining industry is resulting in new mining centres springing up at several points, while old ones are becoming greatly overcrowded.

Unlike the deposits of the Joplin district (Missouri-Kansas-Oklahoma), which are found in the Mississippian series of the carboniferous system, the Arkansas ores occur chiefly in the Yellville formation of the Ordovician system, which is a much older sedimentation than the Mississippian. Overlying the Ordovician and underlying the carboniferous is found the Devonian. The Yellville formation is composed of magnesian dolomites, outcrops being common in northern Arkansas. The base of this system shows no outcropping and its depth is estimated only by deep drilling, which indicates that it may extend down to the pre-Cambrian crystallines. Where the Yellville formation outcrops along the White river its width reaches 500 ft. Whereas the coollite limestone is the guiding geological formation of the Joplin district, overlying the Grand Falls chert or ore-bearing stratum of the sheetground regions, in the northern Arkansas field, the most valuable guide is the Key sandstone occurring in benches and usually marking the cap-rock, overlying the dolomites in which the ore occurs. Fracturing, jointing, faulting and slight brecciation characterize the areas where the mineral is most likely to be found. The ore, when a blende, usually produces a concentrate containing as high as 62 to 64% metallic zinc, with no iron, while the carbonates produce a concentrate or free chunk ore from 38 to 48% metal. The Key sandstone is distinguished through its resemblance to coarse brown sugar and its decomposed formation.

The first mining for lead was in 1818, but not until 1857 was this ore produced on an extensive scale. In the same year zinc carbonate was extracted for the first time. In 1899 prices soared to a point that encouraged extensive mill construction. The greatest activity, however, began about six months ago, since which time about 20 mills, chiefly of the most modern design, have been constructed, and 12 or 15 more are under course of erection or will be built in the near future.

As the ore-bearing stratum usually is found high on the mountain-side, the method of mining is, in most instances, confined to adits on the orebody. Sometimes the

ore formation is simply quarried, and where it is rich enough, mill concentration is sometimes dispensed with and the free carbonate (little blende is mined in this manner) is corded up and sold to the smelter. The ore is sold chiefly in the open market to the highest bidder, although where some producers have made long-time contracts with smelting concerns, the producers are getting all the best of it, due to the fact that the open-market prices have declined materially, whereas the contract settlement is holding firm. The ore goes to smelters in Illinois, Kansas, and Oklahoma, and is reputed to make an exception-

MAP OF ARKANSAS ZINC DISTRICT. SMELTERS ARE AT FORT SMITH AND VAN BUREN.

ally choice grade of spelter, due to the almost complete absence of lead and to the high grade of the metallic content.

The big Hurricane No. 2 mill, operated by John Conness Shepherd of Rush, situated four miles west of Pindall, Arkansas, or 40 miles west of Rush, will be one of the most complete plants in the district. It will be equipped with a 6-ft. by 16-in. Hardinge conical mill, the first of the kind to be used either in the Missouri or the Arkansas district. Shepherd owns the fee to 588 acres on which the Hurricane is situated, having purchased it recently for \$85,000.

Over the Hurricane No. 1, which is a mere 'coffee mill,' the output is 25 to 40 tons of concentrate per week. A carbonate deposit, outcropping on a hill-side, and mined from an open-pit, which now has reached a depth of 85 ft., and a length of 200 ft., supplies the ore. The No. 2 mill will be situated across the valley north from No. 1, and will, for the time, handle only the tailing from the No. 1 property. The new mill will be equipped with a Dorr thickener, 30 ft. diam. by 10 ft. deep, seven Wilfley

*Abstract from Joplin, Missouri, *News Herald*, written shortly before the writer's death in June.

tables, and one Deister-Overstrom slime-table. Feed for the mill will be supplied with a 3-in. pump. The mill will be driven by a Fairbanks-Morse oil-engine.

At the Philadelphia mine (on Clabber creek, at Rush), steam power has been replaced with oil-engines of the Fairbanks-Morse make, one of 100 hp. to run the mill machinery, and another of similar capacity to operate a 600-ft. Ingersoll-Rand compressor. Sullivan jack-hammers are to be used for the lighter work of putting in prospect drifts, while the regulation drills will continue in use driving adits. A new aerial tram $\frac{1}{2}$ -mile long, spanning a deep ravine, will connect the Monticello shaft on the south side of the valley with the mill. The tram will be almost 200 ft. high at its highest point, and will cost \$8000. Mining at the Philadelphia, which is one of the steadiest producers in the Rush field, is carried on from three adits at various elevations above the bottom of the valley. The highest is about 225 ft. above the creek-bed. Beneath this is another 175 ft. above the creek-level. Some workings rise above the floor of the main adit, others below, according to the trend of the orebody, which has 'made' in 'breaks' between limestone walls. The ore from both these adits is sent down chutes, lined with railroad iron, to the mill hopper. From the third adit, which is only 30 ft. above the creek-bed, the ore is hauled to the mill, and hoisted to the hopper. In addition to the two Wilfley tables that have been in use at this property, two additional ones are being installed.

Two large new concentrating plants have just been completed in the south end of the town of New Rush, which is $1\frac{1}{4}$ miles down Rush creek from the old town. These mills are the Edith and the Yellow Rose, the former operated by E. Emanuel and the latter by James McCarty & Co. The Edith gets its ore, a white carbonate, from an adit in the mountain-side, and treats it in a 200-ton plant operated by two 50-hp. Chicago-Pneumatic oil-engines. The mine is situated on a lease from the Buffalo Zinc & Copper Co. The Yellow Rose is equipped with Chicago-Pneumatic oil-engines and has a capacity of 100 tons. The company owns a fee to four acres and has first lease on 40 additional acres.

Although conditions are ideal for gravity milling, the system is little in use throughout the Arkansas mines, and the treatment is much the same as in the average plant where ore is hoisted from a vertical shaft. The one important exception to the rule is the McIntosh mill, a new plant of 100 tons' capacity, situated on an 80-acre lease between the new and the old towns of Rush, and owned by J. C. Shepherd. Steam power, wood being the fuel used, drives the mill. The ore passes from hopper to crusher, then to rolls and revolving screen, thence through the ordinary process of mill concentration, each step, however, being at a lower level than the preceding one. Only one elevator is used, that being to lift the middling back to the rolls.

LEAD EXPORTS from Bolivia during the first four months of 1916 amounted to 1,818,000 lb. In the whole of 1915 the total was 4,855,400 lb., and 3,421,000 lb. in 1914.

Tungsten Near Bishop, California

By Leroy A. Palmer

The new mill of the Tungsten Mines Co. is 8 miles from Bishop. It is the largest tungsten mill in the country, and is expected to be in operation by the latter part of August. The initial capacity is 350 tons per day of scheelite ore.

The mine has been opened by three levels, which give a depth of 215 ft. on the vein. The ore is trammed around the mountain, a distance of 1800 ft., and dumped into the crude-ore bin at the mill. From this a short conveyor carries it to a 500-ton Wall crusher, which reduces to $1\frac{1}{2}$ in. This product goes to a 4-mesh trommel, the oversize of which goes to a bin, the undersize to two sets of rolls, 14 by 20 in. and 16 by 26 in. The oversize is fed from the bin by means of a conveyor to a set of 15 by 40-in. Allis-Chalmers Anaconda type rolls. This product goes to two 4-mesh trommels, the oversize being elevated to two sets of Allis-Chalmers rolls for further grinding. The undersize joins that of the first 4-mesh trommel and is reduced finer in the two sets of rolls mentioned, 14 by 20 in. and 16 by 26 in. These rolls discharge to two 14-mesh trommels, whose undersize goes to an Akins classifier and oversize to the elevator to the two sets of Allis-Chalmers rolls. The product of the latter is separated in a similar pair of 14-mesh trommels, oversize to the elevator and undersize to the classifier. The coarser sand from the classifier is treated on five Isbell tables and the finer sand on four Wilfleys. Slime from the classifier is settled in three 6-ft. Callow tanks and treated on two Deister slime-tables.

Power is obtained from the Nevada-California Power Co., whose lines pass close to the plant. Individual motors totaling 130 hp. are used.

THE ATTITUDE of neutral countries toward gold imports is curious and interesting. It is reported that Holland wished to purchase lumber from Sweden, and as Sweden would not take any gold, such purchase was found to be impracticable, as the two countries possessed more gold than they needed or cared to have. After prolonged negotiations, Sweden agreed to take a certain amount of gold, as a matter of grace, at a price 3% lower than the ruling rate. The transaction was then completed and Holland received its lumber. Thus the extraordinary circumstances occurred of gold being accepted by a State institution only at a heavy discount compared with the currency of that country. The National City Bank of New York remarks in an interesting circular that the Norwegian kroner on April 22 had the proud position of having the monetary values of the entire globe under par with respect to its own value.—Weekly letter of Samuel Montagu & Co., London.

SAND AND GRAVEL production of the United States in 1915 was 76,603,303 tons, valued at \$23,121,617.

Zinc Smelting in Vertical Retorts

*It has been known during the last half-dozen years that experiments were being conducted in Germany with the object of evolving a continuous zinc-smelting process using vertical retorts. The great advantage of such a process would be the reduction of the amount of skilled labor required and the improvement in the nature and conditions of the labor, together with other economic considerations. M. Liebig read a paper before the German Metallurgical and Mining Society in 1913 describing the process and plant devised on this system by Roitzheim

the usual type, the former let into the walls of the retort horizontally, the outer ends being supported by the wall of the furnace. The condensed zinc and zinc-dust are collected in the usual way, but as the condensers of a row of retorts are all on one level, the collection is much easier than is the case with the ordinary furnace having tiers of horizontal retorts. The charging and discharging are both done mechanically. The charging is done from cars traveling over the furnace, and the discharged ash is carried away by conveyors or cars. It will be seen

FIG. 1. PRELIMINARY HEATING DEVICE.

FIG. 2. SCRAPER FOR KEEPING BOTTOM OF RETORT CLEAR.

FIG. 3. COOLING DEVICE FOR DISCHARGE-END.

and Remy. He has more recently described the perfected plant, erected under these patents at the Hamborn zinc smelter of the Aktiengesellschaft für Zink Industrie formerly Wilhelm Grillo, the article appearing in *Metall and Erz* for March 22 last. The description of the process given in the following paragraphs is based partly on this article and partly on British Patents 1338 of 1912 and 732, 6771, and 9314 of 1913. The illustrations are taken from the patent specifications.

It will be seen, by reference to the drawings, that the retorts are mounted vertically in the furnaces. They are fed at the top through special openings, where the charge is given a preliminary heat, itself forming a seal to the rest of the retort. The ash is discharged from the bottom by means of a convenient mechanical appliance. The condensers and prolongs (otherwise nozzles) are of

that the conditions of labor are much easier than with the ordinary furnace. The difficult process of charging the horizontal retorts by hand is entirely abolished, as also is the objectionable duty of removing the residue from the hot retort. It is estimated that the labor force will be halved, and that for most of the work only unskilled labor will be required. The prolongs, as in the case of the modern German practice, are divided down the middle, and the carbonic oxide and other gases evolved during smelting are not discharged into the air but sent to the stack and burnt. The retorts are arranged in two rows back to back, with a central brick chequer-work between, and in a full-sized furnace there would be 40 retorts, 20 in each row. The life of the retorts is much longer than that of the horizontal retorts, as the temperature is uniform, and there is no rough usage in charging and discharging. As the process is continuous, the capacity of the retort is much greater.

*Précis by Edward Walker, in *The Mining Magazine*, July 1916.

In looking through the British Patent specifications mentioned above, it is clear that the application to zinc smelting of the continuous vertical retort or muffle heated from the outside is not patentable, and that the Roitzheim and Remy patents relate to methods of overcoming difficulties in practice. It will be seen also that the retorts illustrated have two condensers, one on each side; whereas in the description by Liebig mention is only made of one condenser.

In Fig. 1 is reproduced the drawing attached to patent 1338 of 1902. The object of the invention therein described is to provide a preliminary heater for the charge, the heating being effected without any reduction of the zinc. The preliminary heater or fitting *a* is formed with a number of small tubes or narrow passages *b*, through which the charge passes. These are surrounded by the flames within an extension of the furnace. The large contact surfaces and narrow cross-sections of the tubes enable the mixture to be quickly and completely heated. From the preliminary heater the material descends into the retort *c* below. The condensers are shown at *d*. The residue is continuously or at short intervals removed at *e*. The mixed materials sink gradually in the retort. The hot gases for heating the retort ascend from the ports *f* along the annular space *g* and then escape through an opening near the top of the furnace.

Patent 732 of 1913 (Fig. 2) relates to a method of keeping the discharge-end of the retort clear of obstruction. In practice it is found that the residue hardens on the walls of the retorts, where they project out of the furnace. At the lower mouth of the retort a rim of slag is formed which would constrict the opening and finally entirely close it if arrangements were not made for its removal. The invention consists of means for cutting away or removing these crusts. The retort *a* is preferably of circular section at its lower mouth, and it is mounted on the support *b*. A rotatable cutter *c*, such as a milling-cutter, or a borer or scraping tool, is mounted on the square shaft *d*. The lower end of this shaft carries a toothed rack, shown at *e*. A pinion *f*, which is rotated by means of a crank handle, meshes with the teeth of the rack, so that the shaft *d* can be elevated and lowered by it. The shaft *d* is held as in a guide by the spindle *g*. This spindle carries the worm *k*. The quantity of charge traveling through the furnace can be regulated by varying the speed and pitch of the worm. The spindle *g* is driven by worm-gears *l*, *l'*. The support *b* is provided with a cooling device, comprising the chamber *m* and the water-supply and discharge-pipes *n*. A chute *o* is also provided.

Patent 6771 of 1913 (Fig. 3) concerns a method of cooling the lower part of the retort, so that the discharged residue shall not contain vapor. If the residue is discharged hot, vapors of lead, zinc, and sulphur are given off, greatly to the discomfort of the workers. The illustration shows vertical retort *a* in a furnace *c*. A jacketed vessel *b*, made of a suitable metal, is fixed at the bottom. Between its double walls a current of water or steam flows, so that effective cooling is obtained. The

vessel is held tightly against the lower edge of the retort, so that it may be considered to form an extension of the retort. It is closed below by a grate, or as shown in the drawing by the residue heaped on the conical plate *c*. This plate *c* is secured to a screw *i*, which screws in the stationary plate *k*, whereby the said conical plate *c* can be raised or lowered. The pipe *d* supplies the cooling water, which flows through the jacket space *g* between the walls of the vessel *b* and runs out through suitable outlet-pipes into a discharge or gutter *f*.

Patent 9314 of 1913 describes internal arrangements within the retorts for facilitating the escape of the gases and vapors and need not be quoted at length.

In examining the illustrations it is well to remember that they are merely sketches and not necessarily working drawings; also that the descriptions in the patent specifications do not necessarily represent the actual practice. In several ways the descriptions in Liebig's article do not tally with those of the specification, notably in the number of condensers used.

The Chilean Nitrate Situation

For the 11 months ended May 31, 1916, the production of Chilean saltpeter was 67% greater than for the corresponding period of the preceding nitrate year. In this fact lies one of the chief explanations of the improvement in the value of the Chilean paper peso and also in the purchasing power of the country. No one knows what the effect of peace is going to be on the nitrate industry, and it would seem reasonable that when the use of explosives ceases there might be immediate stoppage in orders for nitrate, unless the War ended at the period when nitrate is needed as a fertilizer.

One of the surprising features of the nitrate industry, at least to a casual observer, has been that, in spite of the great demand and the high prices obtained abroad, the price of nitrate in Chile has not risen much above the normal figure of previous years. This is undoubtedly due to the fact that when the sudden stoppage of shipments occurred and many men were thrown out of employment in the nitrate fields, thereby making it impossible for them to buy the agricultural products of the south, the Government advanced large sums of money to the producers solely for the purpose of keeping their plants running. They, of course, piled up an enormous supply, which, coupled with a general resumption of work, meant that there was always more nitrate available than ships to carry it. The difference between the price received for nitrate in Chile and that paid by purchasers in foreign countries has been absorbed in ocean-freight rates. Exchange was down when there were no ships to transport the nitrate. Cargo space is a little more plentiful now, and vast quantities of saltpeter are being sold. Gold is coming in, and, being abundant, it becomes cheap; or, to put it another way, one buys dollars with fewer pesos than when gold was dear.—*Commerce Report*.

Frue vanner (21) passed to the tailing-elevator (22). The overflow from the Callow tank (15), together with the tailing of the smooth vanner (25), joined the water from (23) at the centrifugal pump (24) and was elevated to the Callow tanks (16) (17) and (18), which fed the three A. & E. slime-tables (26).

A screen test on the ore after being ground in the Elspass mill showed:

Mesh	%	Mesh	%
On 20.....	10.49	On 150.....	8.34
" 40.....	17.29	" 200.....	4.79
" 60.....	10.49	Through 200.....	39.39
" 100.....	8.19		

This test indicates that the Elspass mill slimes the ore too much for high recovery by concentration. A large proportion of that passing the 200-mesh screen

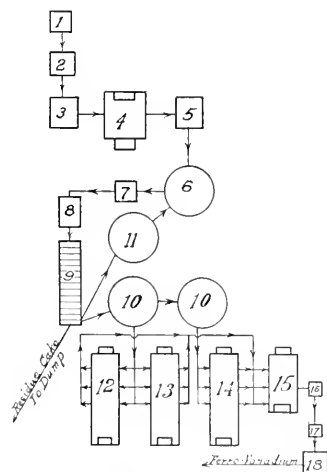

FIG. 3. VANADIUM OXIDE PLANT No. 1.

was lost, as will be seen in the following test on the tailing.

Mesh	%	Assay, % V
On 100.....	30.26	0.0675
" 150.....	24.80	0.0666
" 200.....	9.52	0.0625
Through 200.....	35.42	0.1700

A series of 19 mill-runs was made on lots ranging from 9490 to 21,000 lb. of mill-tailing assaying from 0.1721 to 0.24% vanadium.

To illustrate how some of these tests were made, I submit the flow-sheet No. 2 and the following description:

Mill-tailing treated for further recovery was weighed on the Buffalo track-scales (1), passed through the grizzly (2) into the ore-bin (4), then through rolls (6) and (7) onto the impact screen (8), where the over-size was elevated by a centrifugal pump (9) back to the rolls (7) and the under-size delivered into the Isbell classifier (10), whose spigot discharged onto the Wilfley table (12). The middling from Wilfley table (12) was treated on Wilfley table (20) and the tailing from Wil-

fley table (12), together with the tailing from Wilfley table (20), were sent to the tailing-elevator (18). The middling from Wilfley (20) passed to the corrugated Frue vanner (14). The overflow from the Isbell classifier (10) entered the two-compartment classifier (11) whose spigots discharged onto the two Wilfley tables (13), and the overflow from classifier (11) entered the 6-ft. Callow tank (23) whose spigot discharged onto the smooth Frue vanner (15).

The tailing from the Wilfley tables (13) and the corrugated Frue vanner (14) were sent to the elevator (18), and the middlings from the Wilfley tables (13) were sent to the corrugated Frue vanner (14). The overflow from the 6-ft. Callow tank (23) and the tailing from the smooth Frue vanner (15) were discharged into the 6-ft. Callow tank (19), whose spigot fed the A. & E. slime-table (17).

A set of 16 by 36-inch Colorado Iron Works rolls was substituted for the Elspass mill during the last half of the tests. The tailings were ground to sizes varying from 20 to 80-mesh by these rolls, and an average extraction of 55.35% of the vanadium was obtained. Figures based on these tests indicate an extraction of vanadium not less than 80 to 86%, when treating the ore in the order outlined below.

(1) Crushing with rolls.

(2) Screening.

(3) Concentration.

(4) Re-grinding the tailings and middlings from the Wilfley tables, the tailing from the corrugated Frue vanner, and the over-size from the impact screens of the re-grinding unit, in a Hardinge conical mill.

(5) Screening.

(6) Classification.

(7) Concentration of the re-ground product, and

(8) Concentration of slimes from both primary and secondary crushings.

SMELTING. The treatment of high-grade ore from the mine and of concentrate and slime from the mill by acid-leaching methods is expensive. The insoluble sulphates of barium, calcium, and lead, in the sludge, prevent the recovery of the lead. The elimination of the copper, arsenic, and phosphorus from the vanadium solutions makes the process tedious, complicated, and expensive.

After much experimentation, vanadium ore, concentrate or slime, commercial sodium carbonate, and coal were charged into a furnace and smelted. This yielded metallic lead and a vanadium slag practically free from copper, arsenic, and phosphorus. The results from test No. 35, following, illustrates the method:

	%
Ore assayed, vanadium	3.60
Ore assayed, lead	23.54
Weight of ore exceeds weight of slag per charge.....	32.66
Lead recovered	90.50
Slag assayed, vanadium	5.22
Slag should have assayed, vanadium	5.35
Extraction of vanadium from slag	98.50
Value of lead recovered per ton of ore smelted.....	\$21.19
Cost of flux per ton of ore smelted.....	\$4.56

LEACHING. Pulverize the slag in the crushing unit (1), as shown on flow-sheet No. 3, weigh the quantities on the scales (2), in (3) stir concentrated commercial sulphuric acid into the ground slag until the mass is pasty and charge the mass into the baking-furnace (4). Bake to dry cake, pulverize in (5), lixiviate with water and boil for several hours in the steam-coil-heated, circular, wooden, lead-lined, lixiviating vat (6). During the

waters are used to lixiviate fresh lots of pulverized dry cake in vat (6).

The vanadium liquors from storage-tanks (10) are drawn into evaporating-furnaces (12), (13), and (14), where the water and free sulphuric acid are driven off. The solid material, principally vanadium sulphate, is calcined in the furnace (15) at a moderately high temperature to drive off the sulphur, which, in a semi-molten state, is prepared for the reduction department by granulating it in water (16).

REDUCTION. Mix the vanadium oxide, V_2O_5 , with granulated aluminum and iron filings or borings of low carbon and charge into a 220-lb. capacity hopper (17) in which the materials are mixed. At the bottom of the hopper a screw-conveyor feeds the mixture through an opening into a magnesite-lined crucible (18) large enough to hold the charge. Place a small amount of sodium peroxide on paper in the bottom of the crucible to start the chemical action between the vanadium, aluminum, and oxygen, thus:

The high temperature created during this reaction melts the iron borings with the vanadium, forming the alloy, ferro-vanadium. The aluminum oxide and other impurities of lighter specific gravity form a slag on top of the ferro-vanadium. After cooling, break the slag from the ferro-vanadium, with sledges. This ferro-vanadium (30.55% to 40% V, brittle when cold, after being crushed and sized, is the commercial product.

VANADIUM-OXIDE PLANT. CUTTER, NEW MEXICO.

baking of the cake the excess of the sulphuric acid can be recovered by passing the hot fume through water, making a saving in a 10-ton plant of about \$49 per day. Pump the charge through the acid egg (8) into the sulphate filter-press (9) at about 120-lb. pressure and collect the vanadium solution in the circular, wooden, lead-lined storage-tanks (10). Wash the sulphates in the filter-press (9) with water under a pressure of 120 to 150 lb. and collect the wash-water in the circular, wooden, lead-lined storage-tank (11). These wash-

Two Great Copper Mines Compared

By P. B. McDonald

For several years the Nevada Consolidated and the Calumet & Hecla mines have produced approximately the same amount of metal from ores of nearly the same proportion in copper. The actual mining operations at the two properties are radically different; one is an old underground mine of great depth working lodes of native-copper ore, the other is a 'porphyry' mine extracting low-grade sulphide ore in open pits. One is situated in the attractive Lake Superior region, the other in the sage-brush desert of eastern Nevada. The altitude, climate, and living conditions are in strong contrast.

Taking 1915 as a typical year, the two mined almost the same quantity of ore, 3,077,811 tons at the Nevada mine, and 3,188,583 tons for the mine in Michigan. The Nevada Consolidated recovered 21.61 lb. of copper per

ton, the Calumet & Hecla recovered 22.28 lb. per ton. That the figures are so closely alike is a striking coincidence, particularly when the totally different character of the two mines is considered. The cost to the Nevada Consolidated during 1915 of putting refined copper on the Atlantic seaboard was 8.23c. per pound; this figure, in the words of Pope Yeatman, consulting engineer, includes "all possible charges, such as shipping, refining, marketing, legal expense, taxes, New York and Nevada expenses, and plant and equipment depreciation." The cost to the Calumet & Hecla of producing copper during 1915 was 9.33c. per pound. While this is more than a cent higher than for the Nevada Consolidated, it is partly compensated by the fact that the C. & H. received a price for its copper

nearly a half-cent per pound over the price received by the Nevada Consolidated.

The annual productions of the two mines for seven years is as follows:

	Nevada Consolidated lb.	Calumet & Hecla lb.
1910	62,772,340	72,672,469
1911	*78,541,270	74,130,977
1912	63,063,261	67,856,429
1913	64,972,829	45,916,890
1914	49,244,056	53,691,562
1915	62,726,651	71,030,518
1916	†85,000,000	†80,000,000

*15 months.

†Estimated.

The question of cost of production is an important one for companies treating low-grade ore from which the recovery of copper is but slightly over 1%. An ore of 1% copper means 20 pounds of copper per ton. To produce the metal at 10c. per pound requires a cost for mining, milling, smelting, freight, transportation, construction, overhead, development, and miscellaneous of only \$2 per ton. Taking one year with another, the cost of C. & H. copper is generally given at 10c., that of Nevada Consolidated at 9 cents. The cost at the two mines is apportioned quite differently. At the C. & H., the cost of milling and smelting is relatively low, being not to exceed 2c. per pound. At several of the copper-mills in Michigan, the cost of milling is as low as 1c. per pound on the finished metal. The cost of smelting is perhaps 0.5c. per pound. Any close analysis of the operations of the C. & H. is difficult because the costs on the conglomerate ore, which contributes two-thirds of the mine's output, are higher than those for the amygdaloid ore, which, however, contains less copper per ton. During last year, the C. & H. treated 1,739,984 tons of ore from its famous conglomerate lode, about 55% of the total tonnage milled, and 1,448,599 tons from the Osceola amygdaloid lode, constituting the remaining 45%. The conglomerate ore was more than twice as rich as the amygdaloid ore, yielding 29.74 lb. of copper per ton to 13.32 lb. per ton of the amygdaloid. But the conglomerate ore is both more expensive to mine and the amount in reserve is not large. It is used to sweeten the low-grade amygdaloid. The higher costs on conglomerate are due to the greater depth of underground workings, the consequent heat at that depth, the expense of timbering a loose hanging wall, and the tough angular character of native-copper conglomerate which makes drilling, shoveling, and stamping more expensive. Taking the figures for last year, the mine cost per ton of conglomerate (excluding construction) was \$2.13 per ton. For an average of 29.74 lb. of copper per ton, this means over 7c. per pound on the metal produced as the charge for mining. The total cost of producing copper from conglomerate ore is given at 8.69c. The difference between 7 and 8.69c., or 1.69c., must pay for construction, the cost of which is always high at these mines, for smelting and refining, freight, selling, and all miscellaneous expense. Considering the amygdaloid ore, which in

1915 averaged 13.32 lb. per ton, and for which the mine cost per ton of ore (excluding construction) was \$1.07, this shows a cost of over 8c. per pound of metal to be charged against mining. The total cost of producing copper from amygdaloid ore was 9.71c. per pound, leaving only 1.71c. per pound for all other expense. It is evident that the problem at Michigan copper mines is largely one of cheap mining. The milling and smelting are comparatively simple, the freight-rate to the Eastern market is low by reason of lake transportation, and the selling cost of such an established brand of copper, so much in demand, is small. It is apparent why the management decided a few years ago to conduct a vigorous campaign to lower the underground cost of mining.

At the Nevada Consolidated, the ore was extracted in 1915 for a mining cost of 15.24c. per ton. To this must be added about 25c. per ton for redemption cost of removal of overburden. This capping averaged 155 ft. thick at the Liberty pit, 101 ft. at the Hecla pit, and 87 ft. at the Eureka pit. The redemption cost for the three pits are respectively 30, 22, and 15c. per ton of ore. Taking the average redemption cost at 25c., the total cost of mining becomes 40c. per ton. For ore yielding 22.28 lb. of copper per ton, this figures only 1.8c. per pound of a total cost of 8.23c., a proportion of 22%, against much heavier proportion at the Calumet & Hecla. The cost of concentration is relatively high at the Nevada Consolidated, in spite of the fact that the ratio of concentration is low, being 7.18% for 1915; this contrasts with the approximately 70% metal in the concentrate shipped from the Michigan mills. Only 70.18% of the copper in Nevada Consolidated ore was recovered. It is impossible to compare this with extraction at the Calumet & Hecla, for the simple reason that practically no assaying of Copper Country ore is done. It is not practicable to sample native-copper ore that varies from fine specks to huge masses in a most irregular way. The extraction of copper from Michigan ore has been improved during recent years, notably through the work of C. H. Benedict, metallurgist for the Calumet & Hecla, who pointed-out that in order to save fine particles of copper it was necessary to grind the ore closely enough to liberate these fine particles. Yet it is not likely that the extraction on Michigan ore is radically better than at the Nevada Consolidated. The latter has its own smelter, differing in this respect from the other porphyry-copper mines. As compared with smelting in Michigan, an additional cost comes from roasting the ore before treatment, the proportion of pyrite being relatively high. Freight to the Atlantic seaboard is higher than at Lake Superior, and the general expense of operating in a region where freight and labor are expensive conduce to larger items of cost.

In most ways, except output and grade of ore, these two great copper mines are radically different. The Nevada Consolidated is controlled through ownership in 51% of its stock by the Utah Copper Co., of which, in turn, the Kennecott Copper Co. owns 25%, together with a control of the Braden Copper Co. The Calumet

& Hecla controls a dozen other Michigan copper mines by various stock holdings; the combined output of these subsidiaries is approximately equal to that of the parent mine. Incidentally, the debt incurred in 1908, in consequence of taking over these outside properties, has been almost paid by purchasing the 10-year notes. The Calumet & Hecla recently celebrated the 50th anniversary of its operations, the present company having been organized in 1871, forty-five years ago. The Nevada Consolidated was organized in 1904, twelve years ago. The Calumet & Hecla employs 5000 men, and with its subsidiaries 9000 men, which is more men than is engaged in mining in the entire State of Nevada. The Nevada Consolidated is generally understood to be controlled by the Guggenheims, although their ownership of stock in the company is relatively small. D. C. Jackling is vice-president, and C. B. Lankenau is the resident manager. The Calumet & Hecla is controlled by the Agassiz and Shaw families of Boston, the company having been formed by earlier members of these families when copper mining in this country was in its infancy. James MacNaughton is resident manager and one of the five directors.

As to profit, it is well known that the Calumet & Hecla is the most profitable mine in the world, having paid over \$130,000,000 on a paid-in capital of \$1,200,000; in one year, 1899, dividends of \$100 per share were paid. The Nevada Consolidated has a capital of \$10,000,000, and has paid dividends in the seven years since 1909 of over \$20,000,000 or \$10 per share compared with the par value of \$5 per share. The mine has an assured life of at least 15 years more. This is not a bad record.

Minerals Through the Canal

According to the *Canal Record*, among the 50 principal commodities passing through the Canal during the year ended June 30, 1916, totaling 2,417,46 tons, the following are of interest to mining men:

Mineral	Atlantic to Pacific, Tons	Pacific to Atlantic, Tons	Total, Tons
Nitrates	60	894,079	894,139
Refined petroleum	260,540	10,501	271,041
Coal	213,211	5	213,216
Crude oil	50,033	19,779	69,812
Iron ore	52,250	52,250
Copper	849	35,851	36,700
Copper ore	17,940	17,940
Chrome ore	25,920	25,920
Zinc concentrate	22,079	22,079
Tin	9,205	6,004	15,209
Iron	8,364	4,152	12,516
Cement	11,697	11,697
Explosives	6,986	4	6,990
Lead	476	5,713	6,189
Chemicals	5,207	664	5,871
Gasoline	91	1,936	2,027
Lubricating oil	6,904	23	6,927

During June a total of 124 ships, totaling 400,044 tons passed through the Canal.

Diesel Engines for Mine Power-Plants

By Charles Legrand

*At the Burro Mountain Copper Co.'s plant at Tyrone, New Mexico, are two 5-cylinder, 2-cycle Diesel oil engines, the largest stationary engines of their type in the United States, operating at an altitude of 5550 feet. They drive, direct-connected, two 815-kva., 60-cycle, 3-phase, 6600-volt, 180-r.p.m. generators. The current is used for hoisting ore, driving air-compressors, electric locomotives, and a 1500-ton concentrating plant $3\frac{1}{2}$ miles distant. The load is extremely variable.

These engines are of the vertical design, rated at 1250 h.p. at sea-level. The cylinders are 20.6-in. diam., with 26-in. stroke. Each engine has a scavenging cylinder of 41.25-in. diam. and 23.6-in. stroke; also a 3-stage, 4-cylinder, high-pressure vertical compressor, both directly connected to the engine. This compressor delivers the air necessary for fuel injection and for starting the engine. The scavenging pump, which is larger than usual, delivers air to blow-off the products of combustion and fill the cylinders with fresh air at the beginning of the stroke. This pump was increased in size to be able to fill the cylinders with air at $2\frac{1}{2}$ -lb. gauge pressure at the beginning of the stroke. This gives nearly the same initial absolute pressure, and allows the engine to generate nearly the same indicated horse-power as it would at sea-level. The work done in the scavenging pump is, however, increased and the horse-power available is approximately 95% of sea-level output. The fuel consumption per horse-power is increased over sea-level conditions on account of the extra work of the scavenging pump, and the resulting lower mechanical efficiency of the engine when operating at the elevation of this plant.

Fuel used is California asphaltum base oil, averaging 16 B. and 18,360 B.t.u., costing \$1.85 to \$1.98 per barrel. This is heated to 120°F. Oil of 25 B. is used at the start. Consumption of oil is about 0.78 lb. per kw.-hour.

The cost of power, based on total power generated less that used for auxiliaries in power plant in May 1916 was \$0.0080935 per kw.-hour available. The load factor is 0.62.

Operation of the engines in parallel is satisfactory, even when the load is light. In actual operation, with one engine in service, the peak load carried has been higher than was expected.

The greatest trouble with the engines, not due to carelessness, is with the helical gears driving the cam-shaft. The amount of lubricating oil consumed is being reduced, while the maintenance charge is also expected to come lower. On the whole, operation of the plant has been satisfactory, and the cost is considerably better than with a steam plant of the same capacity run under similar conditions, amply justifying the extra investment for this type of engine where the cost of fuel-oil is high.

*Abstract of paper written for Arizona meeting of the American Institute of Mining Engineers.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

PATENTS to the number of 1036 were issued in one week by the U. S. Patent Office during July.

FITCHER is a good technical term. It signifies the jamming or sticking of the steel in a drill-hole, as happens in ground that is seamy.

AIR-HAMMER drills were probably used first for drilling holes for blasting in the quarries of New England. They were adapted from pneumatic riveters to drill plug-and-feather holes.

AEROPLANES to the number of 398 were exported from the United States in 1915. The value was \$2,960,814, an average of \$7439 per machine. A large export of aeroplane parts was also made.

COMPRESSED AIR is employed by French soldiers in the trenches for throwing bombs. Four men work with bicycle-pumps to make a high pressure of air, and the bomb is shot noiselessly from a piece of pipe improvised as a cannon.

THE COPPER ORES of Butte average 3% copper and 2 oz. silver per ton. The proportion of copper recovered from its ore by the Anaconda company has been increased from 77 to 90%. On 3% ore, this additional saving of 13% represents about 8 lb. of copper per ton.

BLASTING in the bottom of a well is a remedy for increasing the flow of water. It is related that an old well 35 ft. deep "was not providing enough water for a horse to drink." The bottom of the well was partly in rock. A man climbed down and put two cartridges of dynamite in the rock. After the shot, the flow of water was plentiful and clear.

SULPHURIC ACID for use in the leaching process of the New Cornelia Copper Co. will be furnished by a new acid-plant under construction at the Calumet & Arizona smelter at Douglas. This acid-plant will have a capacity of 200 tons per day. The acid will be produced from roasting sulphide copper ores on 24 Herreshoff roasters. At the New Cornelia mine, the acid will be conducted from tank-cars by gravity directly into four storage-tanks of a combined capacity of 150,000 gallons.

STARTING A PUMP that has been under water for over a year is illustrated by an accident at a Montana mine. A pump in the Butte & Zenith mine was under 275 ft. of water. It was of the duplex-sinker type and was in a horizontal position. Compressed air was turned into the pipe-line, and the pump started almost immediately although it had been idle for 15 months. It ran until

the water was lowered 65 ft., when trouble arose in the air-compressor. After the compressor had been repaired, the pump could not be started again, until superintendent Gibson turned 100 lb. of pressure on the air-column, with the pressure released on the water-column, forcing the plunger back. The pump started again and was kept in continuous operation until the shaft was unwatered.

A WATER-SUPPLY was obtained for the plant of the New Cornelia Copper Co. by sinking a 650-ft. shaft in the desert eight miles north of Ajo. Drilling had first demonstrated that water existed there. An electric-pump forces the water through a 10-in. pipe-line to large steel storage-tanks on a hill at the mine, the lift of the pump being 1100 ft. The water is alkaline and of a temperature of 102°F.

A MULE-DRIVER in a Kentucky mine was kicked by a mule, which he had struck with a whip. He tried to recover damages for injuries received. The judge of the Court of Appeals in denying the plea, said, "The mule would have been untrue to itself and to every tradition of its breed, if it had kept its heels on the ground, and an employee cannot court danger by inviting a mule to kick him and then recover for consequent injuries."

BLACK blasting-powder is a mechanical mixture of finely pulverized sodium nitrate with charcoal and sulphur. In making black powder, the original cakes are broken into small grains. These are put in a revolving barrel and are rounded by rubbing together, lessening any tendency of the grains to absorb moisture from the air. The ordinary black powder used in mines and quarries is 73% sodium nitrate, 16% charcoal, and 11% sulphur. The powder is sold in grades varying with the size of the grains, which are as large as $\frac{1}{2}$ in. and as small as $\frac{1}{16}$ inch.

AIR SHOCKS from the explosion of shells have killed men in the trenches on European battlefields. It was noticed after artillery battles that many bodies bore no apparent wounds, and evidently death had come from instantaneous stoppage of the circulation. According to *La Nature* of Paris, the explosion of a high-power shell causes a considerable barometric depression equivalent to the exhausted atmosphere at the top of Mount Blanc, 15,000-ft. altitude. A sudden barometric depression, similar to the experience of an astronaut who descends too rapidly, separates from the blood the air and carbonic-acid gas normally held in solution, and these bubbles become caught in the capillaries and stop the flow of blood instantly. Death occurs from 'gaseous embolism.' This is similar to the form of paralysis, known as the 'bends,' that afflicts miners or 'sand-hogs' working in compressed-air caissons, when, on coming out, they do not remain in the reducing-chamber long enough. These phenomena are dangerous only when the change is too sudden; if the transition is gradual, the blood takes care of the bubbles of air.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

SUTTER CREEK, CALIFORNIA

PROBABLE LAIDOR TROUBLE.—KEYSTONE, OLD EUREKA, ARGONAUT.

An announcement has been made by the following mining companies of Amador county that any demand for a material increase in wages and shortening of hours of labor will be refused and that if such demand be insisted upon, the mines will be closed indefinitely: Plymouth Consolidated, Fremont Consolidated, Bunker Hill, Treasure, Keystone, Original Amador Consolidated, Consolidated Amador (Old Eureka), South Eureka, Central Eureka, Kennedy, and Argonaut mining companies. As a reason for this attitude, the mine-owners call attention to the fact that while the price of copper has increased, the price of gold remains unchanged. The price of supplies such as timber, powder, tools, rails, etc., has considerably increased, and the industry in general is being conducted at a small profit. Attention is also called to the fact that the companies recently made a voluntary increase of 25c. per day in wages. Whether this announcement will have the effect of deferring the threatened strike remains to be seen. Rumors are now current that the walk-out will take place on September 9.

The 1800-ft. station is now being cut in the Keystone shaft at Amador City, and following the company's usual custom the station will be large and well equipped. In this mine, the veins worked in the levels above give evidence of converging at depth, and considerable good-grade ore is known to exist below 1400 ft., so there are excellent indications of opening a large reserve of ore by means of the stopes that will be opened above the 1800-ft. level. Notwithstanding a large amount of dead work done during the past six months, a profit of nearly \$14,000 has been made. The Keystone property has been in almost continuous operation since its discovery in 1851 and has yielded well, although shallow in depth compared with its neighbors. The present company sank the shaft from the 1400 to the 2400-ft. level, equipment has been materially improved, and general conditions are good for economically handling ore opened by the last year's development work. C. R. Downs of Sutter Creek is manager and B. I. Hoxsie is foreman.

Water has been removed from the Old Eureka shaft to the 600-ft. level, and the shaft-timbers above that point have been repaired. Another sinking-pump will be installed so as to unwater more rapidly the levels below. Fairly good progress is expected until the 800-ft. level is reached. It is understood that the fire which caused the shutting-down of the mine 30 years ago did most of its damage at and below this depth. Grading on the steep hill-side is now in progress in preparation for the erection of a modern steel head-frame, but the present one-reel hoist with low wooden head-frame is adequate for current needs. Construction of a timber-shed is well under way, and machinery for the modern saw-mill will soon be installed. A crew of about 25 men are employed, including three shifts of shaft-men.

Carpenters are now engaged in completing the interior of the new 60 stamp-mill at the Argonaut and putting on the corrugated-iron roof. The building is situated on the highest part of the ridge west of the present plant, so there will be no difficulty in the tailing following by gravity to the large dam prepared for the residue. The old 40-stamp mill continues to make a monthly profit of over \$25,000. Interesting tests are made at this plant most of the time.

TORONTO, ONTARIO

FIRES ENDANGER MINING DISTRICTS.—RICE LAKE.—NICKEL.

The forest fires that devastated large portions of northern Ontario four weeks ago, causing a loss of over 200 lives, threatened to destroy the Porcupine district. The mining centres escaped serious losses, with the exception of Munro township, where several lives were lost and the surface plant of the Croesus mine was completely destroyed. A number of prospectors in this area also perished. In some mineralized sections the destruction of vegetation has left the rocks bare, thus facilitating prospecting. The burned-out settlers are being given prompt relief, and the towns destroyed will be rebuilt as quickly as possible. The fires are supposed to be caused by the carelessness of settlers who start fires during

MAP SHOWING WATER-POWER AVAILABLE FOR PORCUPINE

dry weather to clear their land. The disaster has drawn attention to the defects in the fire-ranging service of the Province, and above all to the necessity of strict official control of all clearing operations.

A New York syndicate represented by Henry Cecil of Baileybury, has purchased from Angus MacDonald, discoverer of the Rice Lake goldfield in Manitoba, the properties known as the Gold Pan, Gold Seal, and Gold Pan Fraction, covering 117 acres, the price being reported at \$500,000. It is understood that Bache & Co. of New York are heavily interested. Development will be started without delay, and the equipment has been ordered. The company will be known as the Gold Pan Mining Co. There is now a shaft 125 ft. deep at the Gold Pan.

Notwithstanding reports to the contrary, the site of the Canadian refinery to be erected by the International Nickel Co. has not yet been finally decided upon. The company is understood to have an option on a site at Port Colborne on Lake Erie, but the matter is still unsettled, and it is not un-

likely that a place in northern Ontario may be selected. Meanwhile many centres are making strong efforts to secure the refinery. The question of compelling the refining of all nickel ore in Canada is much to the front in politics. A by-election for the Ontario Legislature is now in progress in Toronto, and the Liberals are endeavoring to make this the principal issue. The building of the International company's branch plant in Canada will not settle the matter by any means, so long as political capital can be made by agitating for more extreme measures.

JOHANNESBURG, TRANSVAAL

REDUCED DIVIDENDS AND PROPOSED DEEPER MINING.

Although statements have been made recently in the Union parliament at Cape Town to the effect that the Transvaal gold mines "are having the time of their lives," a little reflection will show that the speeches made and the results indicated at the many annual meetings of shareholders recently held are giving some cause for alarm. While last year's dividends were less than those in the previous year, there is a considerable decrease in the distributions during the first six months of the current year, compared with the corresponding period of 1915. The three great producers, the Crown Mines, East Rand Proprietary, and Rand Central Mines, whose combined nominal capitals approach £8,000,000 and whose size, development, and equipment were supposed to make results independent of any reverses, are causing stockholders some uneasiness. Take for instance the Crown Mines, the largest gold producer on the Rand. Its declared dividend was only 25% in the last six months, against 20% for the previous half-year, and 35% for the corresponding period of 1915. Such a heavy decline was never expected. The last half-year's unsatisfactory results have been largely brought about by the adoption of the engineer's method of selective mining, which, while it increased the grade of ore sent to the mills by 50 cents per ton, increased the cost to a corresponding extent, and the reduced tonnage treated decreased monthly working profits by something like £20,000. The method adopted was to reduce the stoping widths by leaving the poorer portion of the "reef" in the hanging wall, by substituting hand for machine stoping. The result of this new method was to increase the proportion stoped by hand from 14 to 56%; but although the number of stopes was increased by 37, it was found impossible to send the same quantity to the mills with the above results. Needless to say the former method of working is being reverted to as quickly as possible. Another novel method of testing deep ground is being introduced at the East Rand Proprietary Mines. At a vertical depth of 4000 ft., throughout the whole length of the property, payable ore has practically disappeared, and every effort to discover good ore has failed. With 170,000 tons treated per month, and milling reserves reduced to 4,800,000 tons, some method of expediting the discovery of ore has, if possible, to be adopted. There is a great area south of the three deep shafts still unexplored, but of somewhat doubtful value, on which the future of the East Rand Proprietary depends. At the southern limit of this area the reef probably approaches a vertical depth of 8000 ft. In order to probe this area as soon as possible, it is intended, in addition to following the reef on the incline, to drive two cross-ends from the two Angelo Deep shafts at a depth of 4000 ft., a distance of 1000 ft., and then put down a vertical shaft to the reef supposed to lie at a further vertical depth of 2000 ft. It is anticipated that this will occupy 1 year and cost £200,000. Whether the reef will be found profitable at such a depth as 6000 ft. seems problematical.

In *The Mining Magazine* for August, the Far East Rand and suggested changes in the gold law are discussed by R. N. Kato, this being an abstract of a Government report; also "The Far East Rand and the Government," by H. Foster Bain, who recently personally studied the question.

LONDON

FUTURE OF ZINC SMELTING IN ENGLAND AND EUROPE.—ZINC CORPORATION AFFAIRS.

The great increase in spelter production in the United States has attracted much attention on this side and, especially now that prices have tumbled, questions are being asked as to what the condition will be after the War. It is to be remembered that in pre-War days the world's smelting capacity was equal to its demand for spelter. In the normal course of events consumption would have grown and additional furnaces would have been needed by now. When the various nations again settle down to industry it is fair to assume that the tendency toward increased consumption of zinc, which has been a feature of the metal industry for years, will re-assert itself. There will, however, be an excess furnace capacity. So far as is known, no considerable portion of the pre-War furnaces has been wrecked. The big chimney of the Overpelt works of Beer, Sondheimer & Co. was blown down by the Belgians and other damage done to the works, and Belgian plants near Liege have suffered some damage. It is impossible also to foretell what may happen if the Germans move out of Belgium. Many of the works are in the probable line of fire and if the retreat be bitterly contested, further damage is to be anticipated. In a large way though it is true that no considerable amount of plant has been wrecked, and at the end of the War the furnaces that used to supply the world's demand for spelter will still need to be taken into account. Staff and men will be scattered and many will be dead, but the gaps can be filled, supplies purchased, and in general, the old business can be re-established. If this is not done, the men will work at something else, the plants be converted, and competition will merely be diverted to new channels. The Germans have a large and probably adequate supply of ore within their own boundaries, and, while they were formerly extensive buyers of ore in Australia and elsewhere, but a small part of what they purchased was actually treated in Germany. If the flow of concentrates from Australia to Europe be diverted, it will be Belgian and French furnaces that will suffer more than those actually in Germany. These facts are beginning to be understood here and, without in the least abating the determination to free the world from German domination of the metal trades, the method is receiving more serious thought than at first. Your own greater expansion of smelting capacity is a matter which gives us pause. Doubtless many of the furnaces now in commission in the United States will not be able to run under normal conditions, but among the new plants are evidently a number which, being well built and well financed, can stand competition as well as any in the world. With your domestic ore supplies and these new furnaces, it is to be expected that you will play a larger part in the world's spelter market than in the past. There are also the new furnaces in Japan, though to the best of knowledge here the Japanese are not well fortified with ore supplies. Doubtless they can supplement their local resources by drawing upon China, but how far is an open question. Russia is striving to develop home resources, and Austrian prisoners are already making spelter at Elkhastus in Siberia. With all these considerations to face, it has not been an easy problem to determine how Britain is best to take advantage of the great resources in zinc ores found within the Empire, and especially at Broken Hill and in Burma. In round figures the pre-War production of the zinc furnaces in Great Britain amounted to 60,000 tons, and the local consumption of spelter was 200,000. Since the War started, additions to local works have been made or contracted for that will about double the capacity. Zinc smelting has been started in Australia and Canada. The ideal held up here is that the Empire, having the ore, should at least make within it borders the amount of spelter called for by its own industries. To do this entirely would, however, interfere with the industries of

Belgium, and there is no disposition to do this. Also, it is questionable economics to multiply too greatly the number of furnaces in a world that will already have an over-abundance. The latest proposals therefore look toward co-operation with the Belgian and French smelting companies as well as the British concerns. As a result of negotiations conducted by W. M. Hughes, the Australian prime minister, it is announced that the Imperial Government will finance the movement of Broken Hill concentrates, as Americans have doubtless already learned. The plan is for the authorities to purchase from the mines 100,000 tons of concentrates per year for 10 years. The Government has also agreed to finance the building of Australian smelters capable of producing 45,000 tons of spelter and to buy the product. The concentrates shipped to Great Britain will be distributed to English smelters for treatment. As a first step the Government has actually purchased from the Zinc Corporation 100,000 tons of concentrate, and is allotting this to the British plants for reduction. This was bought on the basis of £25 per ton for spelter, the Government assuming all cost and risk of shipment. These arrangements are to be extended when circumstances permit so as to provide for such French and Belgian plants as may desire to enter the combine. The French plant at Dunkirk is already being allotted ore. All this "socializes" the British zinc industry, to use a word our socialist friends much affect, to an extent that before the War would have been considered out of the question. In effect, the Government assumes the responsibility of providing a market for the miners and, in part at least, for the smelters. It is to act as broker and in this way control the situation without entering the politically dreaded field of tariffs and subventions. Clearly it may make or lose money, or it may do both in turn, but also clearly the Imperial government will for some years to come be an important factor in the zinc business and the old *laissez faire* methods are abandoned. So far proposals for buying ore only extend to Australia. What action, if any, will be taken to control the flood of metal that the Burma Mines will soon be ready to supply, remains unknown.

The contest against the management of the Zinc Corporation that was made at the annual meeting of the shareholders is being continued though with scant success. The system of ownership of British companies when those in control take every means to increase the number of shareholders, opens the way to contest whenever anyone is disposed to spend the money and energy necessary to circularize minor owners. In practice such contests are not common and rarely amount to much. In this instance F. C. Auld, who has in the past achieved some success in such matters, attempted to control the annual meeting but failed. He has since tried to form a committee to pursue the contest but has met with a series of resignations. First W. Graham resigned giving as his reason that a circular had been issued in which he was mentioned as connected with the *Financial Times*, whereas his intention in joining the committee was to act in his private capacity. Sir Edward Samuel was announced as his successor but has issued a letter saying he gave no permission for the use of his name. Later E. Rodocanachi withdrew so that of the original list there now remain only Mr. Auld and three others two of whom have no financial interest in the Corporation. The attempt to interfere in company management by men, none of whom have a large interest and some of whom have none, will probably appeal to American readers as most peculiar, but it is to be remembered that in London company management has become almost a profession, with little relation to the particular business in which the company is concerned. As to the merits of this particular contest, which seems doomed to die before it gets properly started, it may be fairly said that no one who has studied the history and present condition of the Zinc Corporation takes the matter seriously.

On page 372 of this issue electrolytic zinc in Australia is discussed editorially.

LEWISTON, MONTANA

LARGE CEMENT PLANT STARTS WORK.—JUDITH MOUNTAIN COPPER DEPOSITS.

The Hanover Gypsum Co. started its new mill 8 weeks ago. Soon after, the new mill, 1000 acres of land, and the remainder of the property was sold to the Three Forks Portland Cement Co., which operates Montana's only cement plant at Trident. This concern is controlled by Chas. Boettcher and associates, who have already started work on a \$1,000,000 cement plant to be built on the property just purchased near Lewistown. This will be rushed to completion in the next few months, and it is expected to supply much of Montana and the Dakotas from the new plant. Abundant deposits of pure limestone outcrop less than two miles away in the South Moccasin mountains, which can easily be transported by gravity tram to the proposed plant. Extensive beds of clay suitable for cement manufacture also are found nearby.

Mining and prospecting in the Judith mountains is more active than for many years. The Spotted Horse, Cumberland, and MacGinness mines at Maiden are producing regularly. Ore has also been shipped from the War Eagle, and from prospects on the north and east side of the mountains. It is reliably reported that the four lessees of the Cumberland have refused an offer of \$250,000 for their lease and bond, as a result of the recent rich development; at any rate Milo Skerrow has sold his one-fourth interest in the lease to George Wiegand, one of his partners, for \$25,000.—The Mammoth claims near Gilt Edge have been leased after being closed for nearly 10 years; development work is now in progress and it is expected to soon re-open the mill with which the property is now equipped.—Several lead-silver and gold claims in the Cone Butte district, east of Maiden, are opening well, some are being shipped.

One of the most interesting developments this summer is finding copper ore in commercial quantities in the Judiths. On the north side of Red mountain are five claims controlled by E. Sutter and others of Lewistown. Already one car has been shipped, from which it is expected to realize a profit of \$1800 above smelting charges; more ore will follow. The ore mined averages 21% silica, 18% copper, and 25% iron, and includes azurite, malachite, chrysocolla, and the black earthy oxide, melanconite, and some cuprite. Development so far is not extensive, but indications are favorable for the occurrence of a large sulphide orebody in depth. On the Sutter 1, 2, 3 claims oxidized ore occurs in rather irregular bodies in intrusive rhyolite-porphry near limestone. A heavy iron gossan overlies the deposit and there is evidence that the surface ores have been leached, which may indicate a zone of secondary enrichment in depth. In West Annell's Creek valley, a few hundred yards away, there is a vein of pyrite carrying gold and copper. On the Missourian claim somewhat farther away, the copper ore is found near a dike of phonolite. On the south side of Red mountain are four claims owned by Sutter brothers and Hawkins, on one of which, the Copper King, a face of 60 ft. of 1 to 3% copper is exposed. Others have staked claims nearby and considerable interest has been aroused.

In the North Moccasin mountains both the Barnes-King and Kendall properties are regularly producing. Development is being done on the West Kendall, where considerable lead ore carrying gold has been found, and on the North Kendall where a body of low-grade gold ore is being sampled. The Barnes-King company continues to improve its surface equipment.

Oil and gas locations are still attracting interest. Recently the Grass Range Oil & Gas Co. has been organized to prospect for oil on 10,000 acres of leases ten miles S. Range, 35 miles east of Lewistown. Still farther east in the Cat Creek basin near Winnet, Warren C. Wright of Chicago has leased 100 acres on a pronounced anticline, and expects to begin drilling in a few months.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

In Bulletin 642-E of the U. S. Geological Survey, Stephen R. Capps discusses the Turnagain-Knik region. This report covers 48 pages, accompanied by maps. The geology, gold deposits, mines, and prospects are described in detail.

The Cosna-Nowitna and Ruby-Kuskokwim regions are described in Bulletin 642-H by H. M. Eakin, J. B. Mertie, Jr., and G. L. Harrington. The area is east of Fairbanks.

JUNEAU. Commenting on affairs at the Alaska Gold Mines, D. C. Jackling recently made the following remarks: "Conditions are not at all discouraging. As far as we are concerned we pay no attention to stock-market prices. We are interested in the mining end of it. The operating costs are about 65c. per ton. Conditions at Juneau are different than in some other mining properties. We have to take the ore that we have on hand and dispose of it before we can get at other ore. At present we are opening the mine in some new places, and this will probably soon result in an improvement. Conditions are not as good as we expected, nor as good as we ex-

MAP INCLUDING THE TURNAGAIN-KNIK REGION.

pect they will be. But we have faith in the property and believe that we will run into better ore that will show good profits later. Our July report showed the ore was averaging \$1.21 per ton, an improvement over the average shown by the ore treated in previous months. The average for last year was a little over \$1.15 per ton. We look for still further improvement, after the ore that is broken and ready for the mill is disposed of. Alaska Gold is a long-time proposition and must be worked out gradually, as it has an enormous tonnage."

July returns of the Treadwell group were as follows:

	Mexican	Treadwell	United
Ore crushed, tons	14,385	77,721	45,010
Gold yield	\$19,122	\$157,165	\$74,052
Average per ton	1.33	2.03	1.64
Operating expenses	22,096	98,727	77,145
Construction charges	2,124	12,326	11,338
Profit		14,827	
Loss	5,589		15,171
Other income	3,730	11,281	3,730

ARIZONA

BISBEE. Flotation experiments on low-grade silicious gold-silver-lead ores are now being made at the Shattuck-Arizona mine. During July the yield was 315 oz. gold, 22,525 oz. silver, 174,091 lb. lead, and 1,397,445 lb. copper.

CHLORIDE. Firemen and cage-men at the Tennessee mine asked for a raise of 50c. per shift, and because this was refused the whole force at the mine, 175 men, downed tools. An offer of 25c. was made but refused by the men. Water is likely to be a trouble if the pump-men walk out.

OATMAN. At the United Eastern's No. 2 shaft raising has been started from 690 ft. to meet sinking from 590 ft. At the mill two ball-mills have been erected. Three tube-mills are ready to be installed.

CALIFORNIA

ALLEGHANY. On October 4 a meeting of the Tightner Mines Co. is to be held at Grass Valley to consider increasing the capital from \$100,000 to \$750,000, also to change the par value of shares from \$1000 to \$10 each. The mine continues to yield rich ore.

ATURN. The north fork of the American river, between Auburn and Colfax, is to be prospected by the Guggenheim interests. A large drill is being assembled.

HAPPY CAMP. The Gray Eagle mine, known locally as the Dakin & Farish property, 7 miles from Happy Camp, up Indian creek, in Siskiyou county, has been sold to Charles F. Ayre, representing W. B. Thompson of New York. An examination had been made previously by Orvil R. Whitaker. This is a developed copper (chalcocopyrite) mine, with 500,000 tons of 5% ore assured. Evidence indicates this to be one of the most important copper developments in California since the Mammoth came into prominence.

JAMESTOWN. On the 800-ft. level of the Knox & Boyle shaft of the Nyman Consolidated, after driving 30 ft. through the fault the north orebody was cut. Two feet assays \$50 per ton. Ten stamps are crushing 3 tons per day each of \$15 ore.

MARYSVILLE. On August 23 the Pacific Gold Dredging Co., a subsidiary of the Yukon Gold Co., launched a new dredge a few miles above this place.

(Special Correspondence.)—It is expected that the Excelsior mine, situated near Sugar Pine, will be re-opened and operated in a vigorous manner. The property, which produced around \$400,000 in the early days of quartz mining in this county, when a shaft was sunk to a depth of 225 ft., was recently inspected by H. L. Huston, of San Francisco, who, it is understood, will report favorably to the prospective purchasers. The Excelsior is owned by Fred Sutton of Sonora.

Operations will begin soon at the Omega mine, now unwatered to a depth of over 300 ft. While the pumps are taking out the remaining water, the drifts on levels No. 1, 2, and 3 are being re-timbered preparatory to the extraction of ore and further development. It is the intention later to drift from the bottom of the 600-ft. shaft to open the orebodies exposed in the workins above.

Boston people have taken the Bell mine under bond and will begin operations at an early date under the direction of Paul S. Bernard. The ore is low grade, but the vein is large and the property is regarded as one of the most promising in the Tuttle town district.

The Rawhide, which is in the hands of the Silver Peak Mining Co., is being equipped with powerful modern ma-

chinery for extensive development. It has been unwatered to a depth of 1200 ft., and the pumps are still working.

The Cosmopolite mine, near Groveland, has been bonded to a Nevada company said to be strong enough financially to give the property a thorough trial. It is understood that vigorous work will begin at once.

Sonora, August 26.

WOODY. Contracts were let on August 28 by the Weringer Mines Co. for machinery, including a Hardinge ball-mill, Dorr classifier, and Oliver filter, for a flotation plant to treat the sulphide ores of the company's property. These machines will be supplied by Collins & Webb of Los Angeles. A 160-hp. Western gas-engine was also purchased from the Western Gas Engine Corp. of Los Angeles. C. H. White of Cambridge, Massachusetts, is reporting on the Weringer property.

COLORADO

BRECKINRIDGE. The Breckinridge district is shipping 2900 tons of ore and concentrate per month. The largest producer is the Wellington Mines Co., which sends out zinc ore and concentrate. The Comnack company has recently completed a new mill. The Tonopah Placers and French gulch dredges send their gold regularly to the Denver mint.

CRIPPLE CREEK. The Cresson company is to pay dividends of 10% monthly on the 1,226,000 shares, which are now selling at \$5.50 each, \$1 par value. This is equal to \$1,400,000 yearly.

The Independence mill has been stopped, pending re-modeling, which will occupy the remainder of the year. It will then have a daily capacity of 1200 tons, double that at present.

Gold output of the district during August is estimated as follows:

Plant	Tons	Average value	Total value
Golden Cycle, Colorado Springs...	36,800	\$17.00	\$625,600
Portland, Colorado Springs.....	13,000	21.00	273,000
Portland, Victor	19,600	2.85	55,860
Portland, Independence	16,958	1.94	32,898
Caley-Jerry Johnson	2,400	4.00	9,600
Rex	1,860	2.40	4,464
Reed-Gold Sovereign	700	2.50	1,750
Worcester-Rubie	300	2.40	720
Smelters, Denver and Pueblo ...	4,630	55.00	254,650
	96,248	\$13.07	\$1,258,542

On October 1 the Doctor-Jack Pot company pays 1c per share, equal to \$30,000. Profits in the second quarter were \$12,315. Cash assets are \$139,083. The ore averages \$8.55 per ton.

Sinking has been temporarily suspended at the main shaft of the Strong mine at Victor, where a depth of 1500 ft. has been attained. A station for the fourteenth level is now being cut out. Cross-cutting will then be started.

The United Gold Mines Co. has taken a lease on the old Victor mine belonging to the Smith-Moffat estate. Part of the ground will be sub-leased, either on the split-check system or on a slight increase in royalty over that paid by the leasing company to the estate.

LEADVILLE. The Mt. Champion mine is probably to be sold, and it is now being examined. The price is not stated, but the property is valued at \$800,000. Present production is large.

The mines included in the Down Town basin recently drained are the Bon, Bon Air, Valentine, and Weldons to the south, all of them at one time heavy producers of iron-manganese and silver ore; the Home Extension and Cloud City, now steadily shipping a large quantity of iron-manganese; the Penrose, the centre of draining operations; the Elks, Midas, Hussey, Hilschle, Hope, Wolcott, Sixth Street, Coronado, M. E. C., and Northern, a territory known to be rich in iron-manganese extending almost through the entire city from its north and south limits. The mines in this section were without exception last active before the entrance of carbonate of

zinc into the list of commercial ores to be found in the Leadville district. Shipments of carbonate were made from the Penrose dump after it had been idle some time, and when the water was considered too expensive an obstacle to development. Indications of zinc carbonate have since been found in many other properties in the Down Town basin. This knowledge of the presence of zinc throughout the Down Town area, together with the exceptionally strong market that has prevailed for spelter for some time, were the main factors in bringing about the draining of the territory. Now the water has been removed and mining can again proceed without difficulty.

IDAH0

COEUR D'ALENE

Dividends paid by Coeur d'Alene companies in August totaled \$677,175, making \$6,844,670 in 8 months.

BURKE. The Consolidated Marsh Mines Co. has arranged a 10-year lease on certain claims of the Federal Mining Co. The Marsh company is to spend \$40,000 in the Marsh property. Under the lease the Marsh is to account to the Federal company for milling ore on the following basis: When the ore contains 9% lead or less the royalty shall be 35c. per ton milled, and for each unit of lead above 9% the royalty is to be increased at the rate of 25c. per ton for each unit in excess. This rate is to apply when lead is 5½c. per lb. in New York, and when higher than 5½c. the royalty shall be increased at the rate of 30c. per ton for each cent above 5c. per lb., fractions proportionately. The royalty on crude ore is 15% of the net smelter returns when lead is 5½c. in New York, 20% when the price is 5½ to 7c., and 25% when the price is 7 to 8c. The Marsh company also agrees to pay all taxes, and holds the Federal company free from loss or damage by reason of personal injuries, liens, or other encumbrances.

KELLOGG. July profits of the Caledonia were \$90,000. On September 5 a dividend of 3c. per share, or \$78,150, will be paid. This makes \$677,300 for the year.

MURRAY. It is almost certain that the O. W. R. & N. Co. will construct a railway up Beaver creek. The line has been surveyed. It will serve the Ray-Jefferson, Interstate-Callahan, Idora, Tuscumbia, and Virginia, all producing properties, and the Friend, Toughnut, Parrott, Sunset, and several others that will be able to ship as soon as transportation is provided. A minimum monthly tonnage agreement is said to have been entered into with the companies that will benefit, the deficit, if any, to be subscribed pro rata.

PINE CREEK. It is reported that the Coeur d'Alene Antimony Mining Co. of Spokane, operating near the mouth of Pine creek, is to erect a smelter to reduce its ore and concentrate. The mine continues to open well.

MICHIGAN

THE COPPER COUNTRY

Houghton. Additional men are being taken on by the Calumet & Hecla and subsidiary companies. A good class of miner is being attracted to the district. A 10,000-kw. turbo-generator is being constructed for the C. & H. plant on Lake Linden by the Allis-Chalmers company. This machine is to replace two others of smaller capacity. The new one and another at work will supply 17,500 kw. Power consumption is increasing continually. The new leaching plant is said to be working satisfactorily.

At the Lake mine the old Pelt shaft is being unwatered by means of an air-lift.

Concerning the Calumet & Hecla-Tamarack business, the C. & H. distributed on August 31 to its own shareholders 20,000 Tamarack shares, each holder of 5 shares in the C. & H. getting 1 share of Tamarack. Apparently the sale of the latter to the C. & H. for \$59 per share is off.

Calumet & Hecla shares remain steady around \$540; Copper Range are \$60 each.

MISSOURI

JOPLIN. Flotation of slime is being adopted in this district, although somewhat in the experimental stage. Companies using the process are the Voge at Carterville, Martin & Wilders at Chitwood, Wingfield Bertha A. at Webb City, and Picher at Picher, Oklahoma.

Ore prices were unchanged last week, the average for 60% blende being \$61, 40% calamine, \$41; and 80% lead, \$65 per ton. The total yield was valued at \$332,953, making \$23,230.79 for 24 weeks. August production of blende was 5590 tons less than in any other month of this year; April, the largest, was 42,327 tons; August was 15,749 tons. Surplus ore in bins is estimated at 23,000 tons.

MONTANA

BUTTE. The Anaconda company has recently purchased from the Westinghouse Electric & Mfg. Co. a 1215-hp. synchronous motor that is to be used for compressor service in the Leonard mine.

The Butte-Zenith shaft is down 1000 ft., where a 600-gal. electric pump is to be installed. Cross-cutting is to be started on October 1.

LIBBY. A recent shipment of 2561 lb. of concentrate from tailing at the Rose Consolidated Mining Co.'s property near here returned \$1163 in tungsten, according to Harve H. Phipps of Spokane, the company's president. As this property was purchased as a gold mine, the owners are pleased with this extra yield. The tungsten is a high-grade scheelite, and the ore returns \$5 per ton more than the present market price under the contract. The new 10-stamp mill is completed, and only awaits the erection of feeders and wiring for electric lights. The mill is built so that with small expense the capacity can be doubled by adding a Hardinge mill, tables, and other equipment. Three years of ore is blocked out. One adit was driven at right angles to the vein, cutting it at 350 ft. From this a raise 150 ft. to the surface was made in ore all the way. The vein is from 1 to 5 ft. wide, and averages \$12 to \$20 in gold, with tungsten the whole distance. A second adit cut the vein at the same distance from its portal, and a raise about 180 ft. opened ore all the way, where it is a little wider and a little richer. These two adits and raises are 800 ft. apart. The ore has been further proved by small shafts and surface explorations between the two raises. Oscar Nordquist of Wallace is manager of the Rose Consolidated. P. S. Rose of Libby is superintendent.

SUREDOA. Mining in Mineral county is experiencing a good revival. At the Iron Mountain 110 men are employed. The Inter-Mountain is shipping copper concentrate. The King and Queen near Saltese are opening silver-lead ore. The Tarbox is sinking 500 ft. The Silver Cable and Big Elk are extracting ore.

NEVADA

GOLDFIELD. The annual report of the Jumbo Extension Mining Co. for the year ended June 30, 1916, includes the following:

Development covered 8917 ft., inclusive of 595 ft. of shaft-sinking. Development cost \$6.95 per foot, sinking, \$37.06 per foot. In the Pol-overda claim 1252 ft. of work was done. Two promising stringers did not produce large quantities of ore. Exploration continues at 932 ft. The claim yielded 6400 tons of \$30 ore. In the Velvet claim 7665 ft. of work was accomplished. The output was 39,734 tons of \$5.42 ore. The shale-latte orebody has been stoped steadily from the 920-ft. to the 800-ft. level, over 300 ft. on the dip. A large tonnage still remains there. Raises from the 1017-ft. level are being put up to cut its downward extension. The shale orebody found in 1915 has been worked out. One found at 1017 ft. is not profitable. The Velvet shaft is down 820 ft., and at 730 ft. was connected with the Pol-overda shaft. Extensive work is under way on the 769 and 879-ft. levels. Any estimate of re-

serves would be impossible, owing to the peculiarities of the shale-latte orebodies. Mining and development cost \$5.40 per ton. Tests are being made on dump ore and tailing at the Bonnie Claire mill.

The year's output was 35,541 tons averaging \$31.64 per ton, equal to \$1,124,487. Smelter losses were \$4.32 per ton, leaving \$970,785. Total expenses were \$15.82 per ton, against \$18.97 in the previous year. Four dividends were paid, totaling \$465,000, equal to 30c. per share.

At a depth of nearly 900 ft. the Silver Pick Consolidated has cut 3 ft. of \$25 ore, but a sudden rush of water has stopped sinking for the present. The Calyx drill, working from the 500-ft. level, is at a depth of 1130 ft. Several good veins have been cut.

MANHATTAN. Developments at the White Caps mine are of importance to this district. The ore above 210 ft. had been mostly extracted, water was troublesome, and the ore was rebellious. The shaft has since been sunk to a depth of 310 ft. The east drift is out 300 ft., and cut 12 ft. of ore assaying \$30 per ton. The west drift is 22 ft. in ore of high grade. Treatment problems are practically solved. J. G. Kirchen of Tonopah is in charge.

OKLAHOMA

COMMERCE. A boom continues at this and the other new towns in the zinc-lead district, namely, Cardin, Oklahoma, and

PART OF OKLAHOMA, SHOWING ZINC CENTRES.

Picher. The mines have grown at a rapid pace. The ore, which often contains 30% blende, is free and in sheet-ground. Hand-flies make a good saving. The railroad centre of Quapaw is also busy. Conditions in the Miami district are flourishing.

UTAH

ALTA. The Alta Tunnel & Transportation Co.'s adit is in 2100 ft. Large ore bins are to be built at the portal. These are not needed at present, but should be within three months. At least three veins will be cut during the next 500 feet.

In American Fork Canyon the Earl Eagle company is advancing its adit 8 in. daily in hard blue limestone. The face is in 325 ft. A 200-hp. H. Ingersoll-Rand compressor and 25-hp. Fairbanks-Morse oil engine have been installed. The portal of the adit has an elevation of 5500 feet.

EMERY. Besides treating local lead-silver ore, the Utah Minerals Concentrating Co. is treating tungsten ore from sev-

eral places, notably from the Bylesby mine near Lovelock, Nevada. From June 22 to July 22 the plant treated 388 tons, and then to August 22, 542 tons of tungsten ore. The Nevada ore contains 2% WO₃, which is concentrated to 45 and 55%. Garnet interferes with good separation. The recovery is 80%.

SALT LAKE CITY. The Ohio Copper Co.'s property at Bingham was sold at a sheriff's sale for \$750,000 to E. H. Skyes of the firm of Sullivan & Cromwell, Wall street, New York.

TIXTIC. A 25-ton leaching plant costing \$25,000, to treat zinc ore of the Lower Mammoth is to be erected within three months. Development at 1500 ft. in the mine is opening a large shoot. J. C. Dick is manager.

WASHINGTON

CHEWELAH. The Admiral mine, near Valley, and Hecla copper-silver mine, near Chewelah, will be shipping ore within the next two months. Both are newly-developed.

REPUBLIC. Sale of the Republic Consolidated Mines Co.'s property here to the Day interests for \$143,000 is now confirmed. As the new owners have ample capital, it is expected that there will be a much-needed revival at Republic.

CANADA

BRITISH COLUMBIA

Dividends paid in this province during August were \$367,470, making \$2,043,246 for 8 months.

According to Oscar Lachmund, general manager of the British Columbia Copper Co., the main adit has verified diamond-drill work. The 9 by 10-ft. adit is in 1000 ft., and has cut ore. The smelter at Greenwood is kept busy on company and custom ores.

AINSWORTH. At the Florence silver-lead mine there are 70 men employed in construction and development. The hydro-electric power-plant is being erected. A building for the 250-ton mill is half complete. A Broderick-Bascom aerial tram, 1400 ft. long, is to be constructed. The mine contains 200,000 tons of ore.

TRAIL. The Consolidated smelter received 11,487 tons of ore from August 15 to 21, inclusive, a large gain over the previous week. The total for the year is 318,558 tons.

ONTARIO

CORALT. On the 330-ft. level of the Adanac the rich shoot opened at 280 ft. has been cut.—A 2-in. surface vein showing native silver has been uncovered at the Hudson Bay.—The shaft being sunk by joint arrangement between the Peoples and the Ophir, on the property of the former, has reached the diabase, and cross-cutting has been started on the 425-ft. level.

PORCUPINE. There is said to be a shortage of skilled labor at this centre.

A second ball-mill is now crushing ore at the Dome mill. This makes 70 stamps, 2 ball-mills, and 6 tube-mills at work.

YUKON

DAWSON. On August 17, the 20th anniversary of the discovery of gold in the district, the *Dawson Daily News* issued a special edition. Including the estimate of \$4,000,000 for 1916, the gold yield since 1885 totals \$190,000,000.

KOREA

On August 29 the Oriental Consolidated distributes 50c. per share.

MEXICO

HIDALGO

PACHUCA. During July the Santa Gertrudis made a profit of \$7200 from the treatment of 20,282 tons of ore.

More than 20 mining and metal corporations are to be represented by Institute members at the meeting of the A. I. M. E. that convenes in Arizona on September 18. Leading metal producers will have members of their staffs at the sessions, at which 70 papers on all subjects are to be discussed.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

MORTON WEBBER is in Arizona.

S. H. DOLBEAR is at Grants Pass, Oregon.

FORBES RICKARD is again at Lovelock, Nevada.

W. F. FERRIER is examining mines in British Columbia.

HORACE V. WINCHELL was recently at Lovelock, Nevada.

J. P. MONTAGUE, formerly at Tonopah and Manhattan, is at Butte.

H. A. B. MOTHERWELL is with the Arizona Copper Co. at Clifton.

G. T. HOLLOWAY, who has been in Norway, is on his way to Canada.

T. A. RICKARD returned from British Columbia on September 3.

RAYMOND BROOKS is in San Francisco on his return from Manitoba.

NELSON DICKERMAN has gone to Bolivia, expecting to return in December.

HOWARD D. SMITH has returned from London and is now in New York.

H. G. THIELE succeeds P. B. McDONALD as an assistant-editor on this paper.

C. S. WARD has returned to the Onondaga mine, Georgetown, Colorado.

F. W. OLDFIELD has returned to the Cinco Minas, Jalisco, by way of Mexico City.

R. GILMAN BROWN and D. P. MITCHELL have returned to London from Russia.

H. VINCENT WALLACE has been to Oatman, Arizona, and is now at Yellow Jacket, Idaho.

F. L. SIZER has gone to Montana. His temporary address will be at the Silver Bow club, Butte.

NORMAN C. STINES is to remain for another three years with his company at Polevskoj, Siberia.

W. PELLEW-HARREY passed through Vancouver on his way from London to Great Cobar, Australia.

R. B. BRINSMADE has been examining mines in the Metline and Washougal districts of Washington.

H. A. GUESS of the A. S. & R. Co. is on the directorate of the New York & Honduras Rosario company.

GEORGE E. STEPHENSON was at Vancouver last week on his way from London to Prince of Wales island.

B. L. THANE is to continue in active charge of the operations of the Alaska Gastineau Gold Mining Company.

AMASA P. PEAKE of the Western Mines Co., Woody, California, was here for a few days and has gone East.

P. G. MORGAN, director of the Geological Survey of New Zealand, has been appointed Under Secretary for Mines.

DONALD F. LEVIN is engaged in the investigation and establishment of the strontium nitrate industry at Los Angeles.

C. H. ABELING, recently with the Broadwater Mills Co. at Park City, Utah, is with the O. & N. Mines Co., Helena, Montana.

ALFRED H. BROOKS, who for 16 years has been in charge of the work of the U. S. Geological Survey in Alaska, recently paid his annual visit to Juneau.

MYRON A. FOLSON is now in charge of the commercial and legal departments of the Hunter Hill & S. River company, with headquarters in San Francisco.

THE METAL MARKET

METAL PRICES

San Francisco, September 5.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	28.75
Pig lead, cents per pound.....	6.75-8.00
Platinum: soft and hard metal, per ounce.....	\$80-\$84
Quicksilver: per flask of 75 lb.....	\$77
Spelter, cents per pound.....	12
Tin, cents per pound.....	41
Zinc-dust, cents per pound.....	20

Platinum has jumped \$20 per oz. above last weeks' price.

ORE PRICES

San Francisco, September 5.

Antimony: 50% product, per unit (1½ or 20 lb.)....	\$1.00
Chromite: 50% and over, f.o.b. cars California, per ton.....	13.00-16.00
Manganese: 50% product, f.o.b. cars California, ton.....	12.00-16.00
Magnesite: crude, per ton.....	7.00
Tungsten: 60% WO ₃ per unit.....	14.00

EASTERN METAL MARKET

(By wire from New York.)

September 5.—Copper is strong and fairly active, spot metal being scarce; lead is dull and weak; spelter is stagnant and weak.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending
Aug. 30.....	67.25
" 31.....	67.25
Sept. 1.....	68.12
" 2.....	67.75

May	58.21	49.87	56.14	Dec.	49.27
June	56.13	49.63	55.94		

The silver market is strong, with a higher tendency. A big demand for coinage continues in England and Europe. India has been disposed to compete with the coinage orders. Exports from London to India up to August 16 totaled 1,687,500, against 13,975,250 in this period of last year. It is reported that China has parted with as much silver lately as could be spared; but metal is still arriving at Shanghai from the interior, and as long as this movement continues the rise in silver may be retarded.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	30.72	40.26	42.97	Dec.	33.60

Tin is firm at 38.85 to 39.25 cents.

Eastern Metal Market

New York, August 29.

Business in copper is on a more moderate scale, but there is something doing all the time, and the basic condition of the metal is good.

Zinc declined again when consumers covered their requirements. In the past three weeks large quantities have been sold for export and domestic consumption, both prime Western and higher grades having been taken.

Lead is much less active, and the quotations of independents have dropped to the level of the A. S. & R. Co. Exports of lead are light.

The tin market has been quiet and presents little of interest, except that it is firm.

Antimony has turned dull again, and prices will recede unless demand develops, inasmuch as many holders are anxious to sell.

Aluminum is quiet, but firmer at 59 to 61c. per pound.

The steel trade is struggling to meet a demand that exceeds capacity, and prices of some products are stiffening again. In June and July there was a slight abatement of new business in some lines, but full pressure is on again. Steel is not offered today, it must be sought, and then cannot be had if early deliveries are wanted. Pig iron is becoming more active, a pleasing circumstance, especially with regard to foundry iron, the demand for which has been lagging for months despite the call for steel. Foundry grades would have been very active heretofore were it not for the scarcity of molders and other help. The machinery trade is enjoying a steady, healthy demand, although large lists are few.

COPPER

Business continues good, but it is on a more moderate scale. Spot metal is scarce and again is commanding a premium. The refineries are behind in their deliveries because of the recent heat and mechanical troubles. No strikes are reported. Prompt electrolytic is quoted at 28 to 28.50c., with last quarter around 27.25c., and first quarter at 26.50c. Lake, last quarter delivery, is about 27.50c. The metal is in a strong position, statistically and otherwise, and should there be a furtherance of the recent big demand prices will go up rapidly. Most of the late business has been handled by first-hands, dealers figuring but little. The London market was strong yesterday at £129, against £127 a week previous. Exports, August 1 to 29, totaled 27,635 tons. Sheet brass continues difficult to obtain for delivery this year. Customers of the largest producer are reported to be paying 37 to 38c. per lb., but others have to pay up to 40c. Sheet copper, also bars, are quoted at 37c. base, and heavy copper tubes at 41c. Smaller sizes, more in demand, are quoted at 46c. and upwards. A great quantity of brass and copper products have recently been purchased by J. P. Morgan & Co. for export to the Allies. In connection with the future of the copper market the following, appearing in 'Copper Gossip,' the house organ of the National Conduit & Cable Co., is interesting:

"Interests in control of the bulk of American output have maintained a significant degree of firmness lately. It was asserted recently by a representative of one of the dominant factors that the producers are in comfortable shape to the end of the year, without booking any further business. The condition may therefore be fairly used as an argument for sustained strength on the basis of the present copper market. If the foreign inquiries coming from Great Britain, France, Italy, Germany and other countries culminate in sales anywhere near the tonnages mentioned in connection with the feeders thrown out, the transactions will require tremendous shipments to meet all the demands."

ZINC

The market has a quieter tendency and prices are on the decline, but in the past three weeks a tremendous business has been done, both for export and domestic consumption. As was hoped, the brass mills became active and contracted for large tonnages of brass-mill special, while prime Western was active also, and some of the producers are filled to the end of the year. Prompt prime Western was quoted yesterday at 9 to 9.25c., New York, and 8.75 to 9c., St. Louis. Fourth quarter could be had at 8.50 to 8.75c., St. Louis. The producers think that the market is basically strong, although the feeling at London is that the market there will sag. Spot zinc was quoted at London yesterday at £58, against £55 a week previous. Exports to the 29th totaled 10,618 tons. At present domestic consumers are well supplied with metal. Complaint is heard that the recurrent weakness of the market is largely due to the failure of small producers to sit tight when demand eases off. If the market is still for a short time they become worried, and end by offering concessions to induce business. Sheet zinc in carload lots is unchanged at 15c. per lb., 87¢ off for cash.

LEAD

The heavy buying of a week or ten days ago has tapered off, and with the subsidence of business the quotations of independent producers have declined. The A. S. & R. Co. continues to quote 6.50c., New York, and 6.42½c., St. Louis. The outside producers have dropped their New York quotation to 6.50c. They ask the same price at St. Louis. A few days ago they were asking and getting 6.75c., New York, and one sale was reported at 6.80c., New York. For a time while the leading interest was quoting 6.50c. it was not selling at that figure; later it began to sell, but only to regular customers and then it fixed the quantities which were to be delivered. It knows pretty well what its customers require. The London market yesterday was £31 for spot, against £30 a week previous. Exports in 29 days were only 769 tons.

TIN

On the 24th and again on the 28th there were spurts of business, but not a great deal was done, and the week as a whole has been quiet. Spot Banca tin is still a factor in the market, but has not prevented the price of spot Straits from advancing a few points. It was quoted yesterday at 39.25c., with consumers showing but little interest. The arrivals of the month, up to yesterday, totaled 3617 tons, and there was afloat 2235 tons. The manifest of the German merchant submarine *Deutschland*, filed at the Baltimore, Maryland, Customs House, recorded that the vessel had taken in her cargo 181,049 lb. of tin; also 752,674 lb. of nickel. This metal, of course, must have been obtained by re-melting and recovery processes, inasmuch as no firm would dare to ignore England's regulations with regard to exportation of the metal.

ANTIMONY

The market is stagnant again, but the quotation of a week ago—13.50c.—still holds, although a search might find sellers willing to shade this price. Needle antimony is 10 to 10.50c.

Antimony ore: No business is reported, and none is likely with the refined metal so stagnant as it is at present. The last sales recorded were at \$1.10 to \$1.20 per unit.

Tungsten ore: The foreign demand continues, and about 200 tons has been taken for export. Foreign buyers want to buy below the market, otherwise more would be done. In the past week \$20 per unit has been paid by domestic consumers, and negotiations are pending for 100 tons around that figure, although down to \$18 has been quoted.

Industrial Notes

Information supplied by the manufacturers.

Portable and semi-portable air-compressors are described in Bulletin No. B5 of the ZIN-HO MANUFACTURING Co., of Chicago. Methods of driving are electric and gasoline.

The Intermountain Tungsten Milling Co. of Denver is remodeling the Black Cloud mill near Salina, Boulder county, and has given the DENVER QUARTZ MILL & CRUSHER Co., an order for one No. 2 Denver quartz-mill, 8 by 12-in. Denver crusher, and other equipment.

In its 180-page 'directory' the BURD HIGH COMPRESSION RING Co., of Rockford, Ill., gives a tabulation of the piston-ring requirements of almost every automobile of importance made in the United States during the past 10 years; also similar information on other internal-combustion engines.

At the Dome Lake mine, South Porcupine, Ontario, the residue is worth only 40c. per ton. The KOERING CYANIDING PROCESS Co. is highly pleased with the results of its system in this mill. Prior to installation of the cyanide plant the loss was \$1.83 per ton. The mill is now treating 80 tons daily.

Catalog No. 12 of the NATIONAL TANK & PIPE Co. of Portland, Oregon, describes its products, namely, standard water-tanks, patent water-tanks, plain and patent oil-tanks, closed oil-tanks, gravity tanks, storage-tanks, house tanks, half-round stock-tanks, joist foundations, wood and steel tank-towers, and tank-covers. Some useful tables complete the publication.

Polyphase induction-motors; type AA-7a air-compressor for air-brake equipment; type AC-3 air-compressor for air-brakes, stationary equipments, and portable equipments; and compressors for industrial purposes, are described and illustrated in Bulletins 1087A, 1525A, 1530A, and 1536 of the ALLIS-CHALMERS MANUFACTURING Co., Milwaukee, Wisconsin.

The Frontenac mill at Black Hawk, Colorado, has been purchased by the MORSE BROS. MACHINERY & SUPPLY Co., of Denver, who will dismantle it and move the material to Denver. The plant was of 250-ton capacity, consisting of crushers, rolls, tube-mill, Traylor jigs, Card and Heister tables, all electrically operated. The plant was built in 1912, and operated about 9 months. In purchasing the Colorado & Eastern line, 17 miles long, the firm has 185 tons of 60-lb., and 400 tons of 18-lb. rail for sale.

While centrifugal pumps have been a product of the PELTON WATER WHEEL Co. of San Francisco for a number of years, it is only after a careful study of their performances that the firm has decided to place these pumps on the general market. In Bulletin No. 9 the Pelton-Doble centrifugal is described. One of the unusual features is the uni-diffusion system of the volute. This results in high efficiencies. Another convenient characteristic is the over-hung pulley. The belt and direct-connected types of pumps are interchangeable.

The INGERSOLL-RAND Co. of New York recently issued three new bulletins as follows: (1) Form 9024 on steam-condensing plants—Beyer barometric type, described in this journal in the issue of August 5. (2) Form 4122 describing the IR model Leyner drill-sharpener. To those interested in properly formed and sharpened bits, this bulletin will be of timely interest, as it explains and illustrates the sharpener in detail and shows the various styles of bits. And (3) Form 3033 describing the Imperial 'NPV' duplex steam-driven compressors produced to meet a universal demand for a steam-driven air-compressor designed and constructed to operate satisfactorily under high pressures and superheat as well as under ordinary steam conditions.

Book Reviews

COAL MINERS' POCKET-BOOK. P. 1172. Ill., index. McGraw-Hill Book Co., New York, 1916. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$4.

This is the 11th edition, revised and enlarged, of what was formerly the 'Coal and Metal Miners' Pocket-Book.' In this edition matter dealing with mining of ore has been omitted, hence the change of title. But those connected with any class of underground work will find here a fund of information, such as mathematics, surveying, concreting, wire ropes, properties of materials, hydraulics, value of fuels, boilers, compressed air, electricity, explosives, timbering, haulage and hoisting, ventilation, and glossary of mining terms. The book is well arranged, printed on thin paper, is flexible, and should be found worth the price.

THE THEORY AND PRACTICE OF MODERN FRAMED STRUCTURES. By J. B. Johnson, C. W. Bryan, and F. E. Turneaure. Ninth edition, re-written by F. E. Turneaure and W. S. Kinne. Part III. Design. P. 479. Ill., index. John Wiley & Sons, Inc., New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$4.

The latest edition of this standard work has been re-written by one of the surviving authors in collaboration with W. S. Kinne. The general arrangement and the topics covered are, however, similar to the old work. The subject of columns has been treated at considerable length, both from the standpoint of experiment and of theory. Secondary stresses are considered with special reference to their influence upon design. The analysis of plate-girder stresses is unusually complete. The chapters on highway bridges, roof trusses, and mill construction are comparatively brief. The complete list of chapter headings is as follows: Styles of Structures, Working Conditions, Compression Members, Combined Direct and Bending Stresses, Riveted Joints, Plate Girders, Truss Bridges, Design of a Pin-Connected Railway-Bridge, Riveted Trusses, Design of a Riveted Highway-Bridge, and Steel Railway Bridges. The appendices contain general specifications for steel railway bridges, tables of standards, and a discussion of unsymmetrical bending.

HYDRAULIC FLOW REVIEWED. By Alfred A. Barnes. P. 152. Ill., index, and 11 plates. Spohn & Chamberlain, New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$4.50.

In Part I the author discusses the formulae of Chezy, Kutter, and Bazin for hydraulic flow and offers a new formula of the form $v = Kmab$, where K , a , and b are constants for each class of pipe or channel. It should be noted that m and i are the quantities more familiarly known to American engineers under the names r and s , and that K , of course, corresponds to c in the Chezy formula. The various kinds of pipes and channels are divided into 18 different classes, and values of K , a , and b given for each class. The last two quantities are less than unity in every case. Lists of several hundred experiments by different investigators for all conditions of hydraulic flow are given, the velocity actually measured agreeing with the velocity computed from the author's formulae within a few per cent in every case.

In Part II, the author in a similar manner derives simplified formulae for the discharge from triangular and rectangular weirs and circular orifices, comparing the results derived from the formulae with those actually obtained from experiment. The author has done a large amount of painstaking work, and those hydraulic engineers who are not completely wedded to the use of some of the accepted formulae, are in a position to profit from it.

EDITORIAL

T. A. RICKARD, Editor

THE industrial capacity of this country is sold in advance to the middle of 1917.

COST of living, according to *The Annalist*, has risen from 132 in September 1915 to 182.51 in September 1916. These figures represent index numbers of household commodities.

MEXICAN conditions are under review by the International Commission; meanwhile resumption of mining is in progress in several districts. We are glad to hear that the Dos Estrellas, Esperanza, and Mexico mining companies, at El Oro, are again at work.

TWO years ago the four principal banks of Europe, namely, those of England, France, Germany, and Russia, held \$680,000,000 more gold than was possessed in the United States; now the gold supply of this country is within \$50,000,000 of the combined holdings of the four great central banks of Europe.

REFINERY production of copper in August is estimated at 155,000,000 pounds, which is 35,000,000 less than in May. Slow deliveries of machinery and other equipment are said to be retarding smelter production, but by October a further increase of output is expected. At 150,000,000 per month, the annual production of the United States would be 1,800,000,000 pounds, as against 1,225,000,000 in 1913—a 50% increase.

IT is estimated that the extra \$50,000,000 to be paid to the train-men in wages, in accordance with the Adamson Act, will require an increase of 2½% in the freight revenue of the railroads. Last year the New York Central had an income of \$105,000,000 from freight charges; on an 8-hour basis the additional expense would be \$2,625,000 annually. None of these figures begin to reflect the damage done to the country by the bulldozing of Congress.

DURING the fiscal year ended June 30, exports of copper and manufactures had a total value of \$173,916,226, in comparison with \$99,558,030 in 1915. Brass exports totaled \$164,876,044, as against only \$20,544,559 during the previous year. The export of explosives increased from \$41,476,188 to \$467,081,928—a more than tenfold multiplication. Lead and its manufactures increased from \$9,044,479 to \$13,787,774. Machinery, from \$93,863,694 to \$182,677,065. Iron and steel products were exported to the amount of \$621,209,453, as compared with \$225,861,387 in 1915. Finally, zinc and

its manufactures contributed \$45,867,156 to our export trade, as against \$21,243,935 in the previous year. These are eloquent statistics.

AS we go to press, the evening paper announces the collapse of the bridge-structure across the St. Lawrence at Quebec. Apart from the loss of life and money, this is one of the greatest disasters in the history of engineering, because it follows a similar collapse of steel-work in 1907 at the same spot and in the same effort to bridge the St. Lawrence. The earlier disaster was made the subject of a novel, 'Web of Steel,' reviewed in our issue of April 22, 1916. The double event proves that the art of bridge-building is not based on exact science. It calls for a painstaking investigation.

FLOTATION is to be part of the regular practice in the silver mills of Cobalt, Ontario, the product to be treated being slime that has passed over concentrators and old tailing. At the McKinley-Darragh the residue now contains only 0.9 oz. silver per ton, after flotation. The Buffalo company is just completing a 600-ton plant. Other flotation units are being erected, one of 500 tons at the Nipissing, another of 100 tons at the Coniagas, another of 200 tons at the Dominion Reduction, and one of 100 tons at the Northern Customs plants. Beneficiation of the silver-cobalt-arsenic-nickel ores of this district will be considerably improved by flotation. The silver ore of Tonopah is much easier to treat by cyanide than that of Cobalt, and the question of freight on concentrate has to be considered in Nevada, so it is not likely that flotation will be applied there as largely as in Ontario.

RHODESIA made the mistake of adopting the apex law at about the time when most of us in this country had begun to wish it had never been introduced. Now the London courts are being treated to a lovely example of the interminable kind of dispute engendered by the extra-lateral doctrine. The suit, between the Amalgamated Properties and the Globe & Phoenix companies, was commenced last October and was continued for 122 days, until the end of July, when it came to an abrupt stop by reason of the illness of the defendant's leading counsel. His illness is not surprising, seeing that he had been speaking for 23 days before his strength failed; he asked for an adjournment in order that he might recuperate his energies, but the plaintiff objected; eventually the Judge decided that part of the summer holiday must be sacrificed and the hearing was resumed on August 21. The problem before the court is the old one as to the

identity of veins: whether there are several formed at different periods or only one with branching veins. The discussion is proceeding. The point at issue will be decided on scientific grounds at the Greek kalends.

ON September 18, and the remainder of that week, the American Institute of Mining Engineers will hold a meeting in Arizona, the various sessions being distributed among the towns of Douglas, Bisbee, Globe, and Phoenix. Preliminary announcements indicate that the chief metal-producing districts will be visited, besides other points of interest. This is the first time the Institute has held a meeting in Arizona and it is expected that the attendance will be large. At Douglas the technical discussion will be devoted to smelting; at Bisbee to mining geology; at Globe, one day to mining and smelting, another to leaching, and a third to flotation. Advance-sheets of the papers to be presented at these sessions indicate the probably unusual interest of the discussions to be elicited. The committee in charge of local entertainment is headed by Mr. Gerald F. G. Sherman, aided by Mr. Arthur Notman as secretary.

DISCUSSION begins this week with a letter from Mr. J. R. Finlay, replying to our editorial comment on the views expressed by him in a recent address before the Colorado School of Mines. We are glad that Mr. Finlay should have submitted a rebuttal, for we feel sure that our readers will find it interesting. Next, Mr. F. F. Sharpless, a mining engineer of distinction, writes from New York to comment upon the suggestion made recently by Mr. Harold French, who suggested a scheme for prospecting. The objections raised by Mr. Sharpless are reasonable and serve to illustrate further the great difficulty of organizing exploratory work. The account of the procedure adopted by a particular organization and the results of it are much to the point. In regard to selection of books suitable for use by the nomadic members of our profession, we publish suggestions from Messrs. Claude Ferguson and Arden Proctor. We shall be glad to hear from others. Mr. W. R. Sherman suggests a simple code for signalling. Mr. A. B. Peckham, who wrote the original article on cyanidation at the Comaezan mine, in Salvador, replies to Mr. C. O'Brien's criticisms. The C. C. D. system does not lend itself readily to discussion, but we hope that this fact will have impressed itself less on the readers than it has upon the contributors to this department of our paper.

Flotation Royalties

On another page we publish verbatim the agreement made between the Minerals Separation Limited and two great copper-mining companies, the Anaconda and Inspiration. This agreement and another, made previously with the Anaconda company, were included in the evidence taken in the Minerals Separation v. Miami suit tried at Wilmington last year; they formed part of the

court record and are therefore public; we simply obtained a copy as anybody is entitled to do. And we did this because these contracts are likely to serve as a measure of the damage to be claimed by Minerals Separation in case this company's patents are upheld. As the number of those disregarding the patents, under the belief that they are invalid, is at least as large as the number of those licensed by Minerals Separation, it is likely that this contract will be studied with interest by many of our readers. Out of the 25,000,000 tons of ore now being treated by flotation in the United States, we estimate that fully one-half pays no royalty and expects to pay none. Accurate statistics of tonnage are not available, for obvious reasons. The chief alleged infringers are the Jackling group of copper companies, the Miami, the Butte & Superior, and the operators in the Coeur d'Alene. To them the decisions in the two pending suits will prove important. The more important, the Supreme Court decision in the Hyde case, is expected in November, while the pronouncement in the Miami case by the first-trial court at Wilmington is due during the current month. Hence the question of royalty is pertinent. The unprejudiced reader will agree with us, we believe, that the royalty charged to the Anaconda and Inspiration companies is not excessive; it ranges from 12 to 4 cents per ton of ore treated, in proportion to the tonnage. At the present time these companies are treating an aggregate tonnage of fully 30,000 per day. According to the terms of the agreement they would be paying 9 cents per ton on the first 10,000 tons; they would be free of royalties on the next 5000 tons, up to 15,000; they would pay 8 cents on the next 15,000 tons, so that the average would be 7 cents per ton on the 30,000 tons treated. Taking a royalty of 12 cents on a 1% ore, containing 20 pounds of copper at 20 cents, for example, the rate is 12 cents per \$4, or 3%. On a 2% ore, it would be 1½%. This assuredly is not an excessive tax, provided the Minerals Separation represents the real inventors of the process, as to which we should venture to express a pious doubt even after the Supreme Court had decided otherwise, having read the record ourselves. In the Anaconda agreement the royalty is specified up to any tonnage above 6000; evidently the rapid extension of the process led to the making of the later and more comprehensive contract that we publish. Of course, on these big tonnages the Minerals Separation company gathers a lordly income; 7 cents per ton on 30,000 tons daily represents about \$750,000 per annum. A royalty of 10 cents on the 25,000,000 tons being treated in this country alone would represent \$2,500,000 per annum. Evidently the fight over the patents involves a great deal more than a scientific principle. Moreover, the patent-owning company is claiming royalty not only on the ore treated in the flotation machine but on all the ore that enters a mill in which the process is used; they have claimed it on ore removed on a picking-belt and on jigs or tables previous to frothing. Another factor prejudicial to the welfare of the mining industry and irritating to the licensees of

Minerals Separation is the clause, appearing in the Anaconda contract, whereby any improvements or discoveries made by the licensees shall be made known to the licensors, to be patented on their account by them. The licensors agree to give "all assistance, information, and advice in their power as to the working of any of the said inventions," but it has been the experience of several licensees, as they have informed us, that once a contract has been signed the interest of the licensors in aiding their clients has decreased rapidly. Moreover, in several cases, the original plant and mode of operating introduced by Minerals Separation have been discarded in favor of better methods or more efficient machines devised by the licensees, who are still under legal compulsion to pay royalty. Again, the licensees are not permitted to "communicate any detail connected with the working of any of the said inventions to any third party not being a licensee." To this the sheaf of informing papers presented at the Arizona meeting of the Institute by engineers in the service of the Inspiration and other licensed companies is a sufficient reply. Finally, we remind our readers of the illegal contract forced by Minerals Separation upon metallurgists in the employ of licensees, as made clear in our issue of February 5, 1916. All these efforts to place an embargo on the spread of knowledge and the publication of technical information have failed, and we are proud of having contributed to the failure. The flotation process invented by Elmore and modified by Froment was developed mainly on Australian practice, but the process as used today in the United States has been developed during the last three years by American metallurgists most of whom were, and are, outside the employ of Minerals Separation. We sympathize with the good feeling of those in technical control of the operations at the Inspiration and Anaconda mines in their willingness to recognize the good work done by the Minerals Separation people and their appreciation of the help given in treating a low-grade product profitably, but we have no less sympathy with the numerous operators that have had the muzzle of a peremptory contract leveled at them, with sundry preposterous clauses, in a spirit so overbearing as to provoke instant opposition. Such powerful companies as the Anaconda and Inspiration have made terms by no means onerous, as will be seen, but the smaller operator has had to pay a larger royalty, up to 25 cents per ton, and, what is worse, to tie himself by conditions stultifying to himself and to his staff. On gold ores the royalty is usually 25 cents per ounce, or 1 1/4%. This also is small, provided the patents owned by Minerals Separation cover the basic invention. But again we say that the question of royalty would have raised no antagonism if the attempt to enforce it had not been accompanied by other demands, some of them illegal and others only irritating. The fat is in the fire; the so-called infringers are led by a group of rich and resourceful men; it is quite certain that no compromise is now possible and that the fight is to a finish.

Decomposition of Cyanide

Mill-men are familiar with the odor of hydrocyanic acid gas in a cyanide plant, particularly in damp weather, but few have troubled to investigate the cause of it. By the dissolving of precious metals in cyanide solution and their subsequent precipitation, most of the cyanide is lost, that is, a weak solution is made up to working strength by adding cyanide salt, but during the cycle of operations the solution returns to its original weak point, therefore the salt added is consumed. Chemical and mechanical causes account for losses of cyanide, the principal ones being reactions with the ore, atmospheric decomposition, waste in residue, and leakage from tanks. These losses are not the same in any two mills, even on similar ores. Cyanicides in ore and water are always present, and usually they can be checked, but not without constant attention. Mechanical losses should be reduced to a minimum without much trouble. The average metallurgist knows that air plays an important part in cyanidation, also that it causes decomposition of the solution, but he has been content to assume that this was unavoidable. And his conclusion is not far wrong. On another page of this issue we publish the results of a thorough investigation into this matter made by Messrs. G. H. Clevenger and Harry Morgan at Stanford University. In 1909 the former observed that when a plant was treating below its capacity, consumption of cyanide per ton of ore was greater than when working at full capacity, although the quantity of solution in circulation was similar for both tonnages, giving the air equal scope for action. Laboratory tests made at a plant in Central America showed that after 216 hours' exposure to the mill atmosphere only a trace of KCN remained. Several kinds of cyanide with different solutions were tried, confirming previous tests, although there was less decomposition in the mill-solutions than in those from fresh cyanide to which no protective alkali had been added. Light has practically no effect on the decomposition of solutions, as was proved by exposure for 192 hours in light and dark stoppered bottles. In 1912, Mr. A. J. Clark made a similar test at the Homestake, showing substantially the same decomposition. Julian and Smart, Thorp, Clennell, and Watt have discussed atmospheric action on cyanide in their books. While studying these reactions, Messrs. Clevenger and Morgan found it necessary to determine cyanide, cyanate, hydrate, carbonate, ammonia, and formate in cyanide solutions. This work necessitated careful research. Next they exposed solutions of a particular strength to the air in 5 1/2-inch beakers. In two series of tests when no alkali was added, a steady loss of cyanide was observed; but where alkalinity was kept constant the rate of decomposition was lowered, but never so low as without alkali. A study was made of the gaseous products of atmospheric decomposition of solutions, with the discovery that most of the reaction involves the formation of HCN. Other products are an alkaline carbonate and ammonia. In addition to

atmospheric action, there is the decomposition known as hydrolysis, having the equation

This proceeds until equilibrium is established for the particular concentration of cyanide in solution. A mill-solution that contains no protective alkalinity may lose some of the HCN through normal hydrolysis, but if sufficient air be brought into contact with the solution a large part of the cyanide may be lost through progressive hydrolysis. Hydrolysis may be defined as the chemical decomposition of a compound that ensues when the group H_2O is absorbed by it, causing the formation of new compounds. Cyanide plants that operate with a low alkalinity run the risk of losing cyanide owing to the accumulation of the soluble alkaline carbonate, K_2CO_3 , which does not afford protection against the CO_2 of the air when the real protective alkalinity (lime) has disappeared.

In another part of their paper, the authors discuss investigations on the Rand during 1915, an abstract of which was published in this journal under date of January 8, 1916. In treating 25,701,954 tons of ore, there was consumed an average of 0.4 pounds per ton. A number of tests on typical sand and slime showed that the loss of cyanide, due to the escape of HCN as gas into the air, was from 44.7 to 49.5%. Loose or incomplete covering on sump-solution tanks did not suffice to prevent loss of alkali or cyanide. In weak solutions there is no loss of HCN as total cyanide, and but little loss as free cyanide, so long as a protective alkali is present. When the protective alkalinity is below 0.01% NaOH, the loss of HCN as free and total cyanide becomes serious. The presence of zinc considerably decreases the loss of HCN by hydrolysis. Another investigation covered the exposure of working solutions to the atmosphere under varying conditions. While transferring solutions from slime treatment vats at one plant, as much as 0.14 pounds of sodium cyanide per ton of slime disappeared by evaporation of HCN. It was concluded that the loss is greater in pure synthetic solutions, when making tests, even with added alkali, than is the case with ordinary working solutions, and a heavy loss is shown in the presence of little or no protective alkali, when determined with additions of ferro-cyanide. By fitting tight covers to treatment-vats and solution-tanks a saving of 0.09 pounds per ton of ore might be effected. Regarding hydrolysis, it was ascertained that simple solutions decompose by this action; higher temperatures accelerate this decomposition; the alkali formed as a product of hydrolytic action has little or no protective effect on the remaining cyanide, so that hydrolysis proceeds until all the cyanide is destroyed; and that the protection afforded by adding an excess of caustic alkali is only of temporary value. Messrs. Clevenger and Morgan attacked the problem in the same general way as the African metallurgists, but completed most of their tests before the latter began. Generally our authors agree with them, but are not in accord concerning the protective alkali. Whether atmospheric decomposition of

cyanide is worth the study of mill operators is answered by concluding that (1) it may become a serious factor with solutions containing little or no protective alkalinity, (2) the cyanide lost through reactions with oxygen cannot be economically recovered, and (3) the most effective method of preventing decomposition is to maintain a sufficiently high concentration of alkaline hydroxides in the solution.

Australian Spelter

In our last issue we published an interesting letter from our London correspondent, commenting upon the future of the zinc-smelting industry in its world-wide aspect and referring to the recent purchase by the British government of 100,000 tons of concentrate from the Zinc Corporation on the basis of £25 per ton for the metal. This shipment of 100,000 tons is to be distributed among the smelting plants in Great Britain, their total capacity being about that much per annum, as compared with 60,000 tons before the War. In previous issues we have referred to the Australian zinc problem, that is, the question of treating the 500,000 tons of zinc concentrate produced at Broken Hill. Formerly this product was smelted in Belgium and Germany. There has been much talk concerning the building of new smelters in Great Britain, which consumes annually 200,000 tons of spelter, or just about as much as Australia produces, but nothing has been done toward the erection of any big plant because pre-existing contracts and other obstacles intervened. As stated in our Metal Market Review recently, the British government has agreed to purchase 100,000 tons of concentrate per annum during the War, and for ten years after the War. Moreover, the same government will purchase, annually for 10 years, 45,000 tons of spelter produced in Australia, this being the equivalent of 112,500 tons of concentrate per annum on an average assay of 40% zinc, besides 6% lead, and 9 ounces of silver per ton. Thus 212,500 tons of concentrate is marketed. Altogether, adding the tonnage already under contract in Australia, not less than 250,000 tons per annum is sold. Negotiations are pending for the sale of the remaining half of the output to France and Belgium. A sum of \$125,000,000 is involved in this deal between the British government and the Australian mining companies. The transaction is due to the initiative of Mr. W. M. Hughes, the Federal premier, and to Mr. W. S. Robinson, a distinguished director of mining companies in London. Finally, it is announced that the Imperial government has arranged to advance \$2,500,000 toward the cost of erecting the necessary smelting plant in Australia. While these plans go far to solve the Australian zinc problem, they do not settle it conclusively, for fully half the output of concentrate remains in the air, so to speak. However, this recent development will interest zinc producers in this country for many reasons, one being the lessening chance of our own domestic market being flooded with Australian ore.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Imponderables

The Editor:

Sir—While I have no objection whatever to your editorial on my address, I am not altogether pleased at giving the impression of being a worshipper of the output of coal and iron.

It seems to me the great imponderable is *mens sana in corpore sano*. This includes everything, even greatness of soul. It is no simple thing, but a marvelously subtle and complex aggregate of balanced qualities—not an exaggeration of any virtue. Even greatness of soul may be exaggerated into a stupid vice. We look upon the Hindoo ascetic who vows to show his fortitude to God and man by holding his hand over his head until his arm withers and becomes useless, as a mere travesty of a man. The healthy minded Anglo-Saxon thinks that he will do better to use both his hands as well as his head and that God will love him just as well if he exerts himself to be comfortable as if he exerts himself to be miserable. At any rate he exerts himself.

I think one of the manifestations of his mental and bodily vigor is his success in industry. To say that this success is obtained at the expense of losing out in other directions is to my mind absurd. The illustrations you use to point toward the great mental impulses that come from non-industrial peoples do not prove your case, but the contrary. For instance: You say that the Hebrew race was denied industrial participation. Was it? Were not the Jews a part of the Semitic race, which held for many centuries the industrial and commercial leadership of the Mediterranean? Are not the Jews of today as well known for their materialism as for their idealism and do not they produce in every country high examples of both?

The age of Pericles was the age of the industrial and military supremacy of the Greeks. In the days of Virgil, Italy was the political, industrial, and military leader of the world. The same England that produced Shakespeare, produced at the same time Queen Elizabeth and Sir Frances Drake. In the same country Tennyson was the contemporary of Bessemer, and Byron was a contemporary of Watt. Your Oxford is a suburb of the industrial centre of the world; Huxley lectured in the heart of London; and the people of Boston, much as they might value your compliment to Harvard's intellectual prowess, would be likely to remind you that Cambridge is in the heart of a great industrial centre. The same Germany that produced Goethe also produced the Krupps. I have no doubt that Russia having produced

its Tolstoi will come along with some industrial genius.

When Van Dyck and Rembrandt painted in Holland, that country was the leader in trade. Louis XIV was the patron of Moliere. Your argonauts of California brought with them Bret Harte and Mark Twain, and Homer sang of the explorer Odysseus. The country that produced Lincoln and Julia Ward Howe had at the same time Rockefeller and Armour. The country of John Knox is that of Carnegie.

You say the type of man who runs a steam-shovel "is more likely to read the tape than to read Shakespeare." Well let us get down to that: Who reads Shakespeare? Speak it gently: It is the hustling German!

Prospecting

The Editor:

Sir—Suggestions as to a practical manner of prospecting are always interesting, but I fear that some of the uninitiated, who were addressed in the communication of Mr. Harold French, in your issue of July 22, would be disappointed should they attempt to follow his suggestions too closely.

In the first place I am not at all sure that you are wise in giving space to suggestions that are made for the benefit of those who are thinking of "taking a chance," that is, our citizens who are but slightly interested in mining—the average banker, broker, merchant, tradesman, or small capitalist. Such men are not reading technical journals relating to mining and the papers they do read do not care for that kind of copy. Your readers are largely men with a little or with considerable knowledge of mining and generally have their own conception of the proper method of conducting prospecting operations and I fear will not give very serious consideration to theoretical suggestions as to the best way in which to spend small sums for that purpose. Being one of this class myself and, as noted above, interested in the subject, I would appreciate an opportunity to read of successful prospecting enterprises, the method of financing, the manner of working, what was done, what was found, and what was done with the find.

I have had some years of experience in this line of work but I was never so fortunate as to find and develop 150,000 tons of \$8 ore with \$5000 as in the supposed case of Mr. French, and while not denying the possibility of such attainment, I doubt its frequent occurrence.

There are several practical difficulties in the way of such an attractive undertaking. The employment of a "mining engineer who is qualified to conduct a geological survey and to direct the efforts of prospecting parties," at a salary of \$250 per month for the month of June, with the possibility of the work being discontinued or extended over another month or two, will be a hard order to execute. The summer months are the busy days for such independent engineers as could take such short engagements and except in rare instances of temporary unemployment, they are not available at such figures. No more are "skilled assistants" easy to find at \$100 per month.

Again, three miners and three muckers "driving several hundred feet of tunnels, sinking shafts, and making cross-cuts" thus demonstrating 150,000 tons of \$8 ore, would not only have to be very capable men but would have to be provided with something better than candles or carbide. Aladdin's own lamp would certainly have to be a part of the outfit.

Having asked for the methods of other operators in prospecting or exploring, it may be pertinent to mention the methods of procedure followed by one or more of the organizations with which I have been connected. An organization that had been operating successfully for several years desired to secure some new business. Their consulting engineer selected a man to scout for them. This man was a technical graduate, had been an assistant in a number of examinations, and had spent three years in subordinate positions in mines and mills. He was not a trained geologist, experienced mining engineer, nor a high class metallurgist. He was a bright intelligent graduate with quite a varied practical experience, and was worth about \$250 per month, and that was what he was paid on engagement by the year. There was nothing in the contract in relation to participation, but from the action of the directors in previous instances, it was pretty well understood that if he brought any good business to them it would be to his material advantage. He was sent scouting in districts named by the directors. Broadly speaking, he was instructed to look for new business, but more particularly for things of prospective value that possessed indications of developing into something of importance.

It was found that this man's expenses amounted to approximately \$10 per day while away from the home office, or the total expense, salary included, amounted to about \$6000 per annum; this included his traveling, the employment of a few helpers from time to time to assist in sampling or digging prospect-holes, assaying, some local legal expense and, in fact, everything connected with the scouting.

The practical result in three years of this work was that about \$5000 additional was spent on prospects that developed nothing, his principals became interested as minority stockholders in three producing mines which he had brought to their attention. One very promising prospect was taken up on which \$10,000 was spent, by a newly organized and subsidiary company.

The location of this prospect and its cropping was such that a complete sampling of the surface over a width of 20 ft. and length of 1500 ft. was possible, also five cross-cuts were pushed into the vein at an average depth of about 50 ft. from the surface, and short drifts were run at the intersection, thus giving a very fair indication of what values to expect in the 100,000 tons of ore nearest the surface.

About 1000 ft. of cross-cuts and drifts were run, about four months' time was consumed, a little less than \$10,000 was expended, the value of 100,000 tons was indicated,* but not proved. Conditions for cheap prospecting were exceptional, the expense of driving and cross-cutting in rather hard, tough material, scarcely reaching \$5 per foot, the other \$5000 being used in sundry overhead and traveling expenses incidental to this operation.

The foregoing, from an actual experience, was far less profitable than the hypothetical case of Mr. French, but is probably much closer to what might be expected in practice. It was, however, sufficiently profitable to warrant the organization continuing the practice over a gradually broadening field, resulting in the acquisition of five prospects that have developed into mines as well as the acquisition of control or minority interests in a number of operating or more fully developed properties.

A Traveler's Library

The Editor:

Sir—Referring to the communication of 'Subscriber' in your issue of August 12, the following observation concerning books suitable for a traveler's library may prove of value. It is my experience that such books should not be printed on coated paper. A library, especially that of an engineer, is at times subject to hard usage, such as a book printed on coated paper will not withstand. If such a book should get wet, unless the accident is discovered immediately and pieces of blotting paper placed between the leaves, the book is ruined. In camp, 'forty miles from nowhere,' this is not always an easy thing to do. I had my Hoover's 'Concentrating Ores by Flotation' ruined in this manner. This was a beautiful book printed on a fine grade of coated paper. It received a thorough soaking, and when I got a chance to examine it, some days later, I found it to consist of a solid block of paper pulp, neatly bound in cloth. Several other books which I had with me at the time were similarly wet, but, being printed on ordinary uncoated paper, suffered little damage in comparison.

I believe the thin bible paper (India paper), now almost universally used in our various engineers' pocket-books, to be the ideal paper for books for the traveler and

*When this ore was mined and milled two or three years later, it was found that the indicated value and tonnage, or probable ore, checked very closely with the quantity and value of that mined from the area of the vein considered.

engineer. It is light and strong, and the pages will not stick together on being wet. About everything has happened to my Trautwine that could to a book without completely destroying it, and it is still 'doing business at the same old stand.'

CLAUDE FERGUSON.

Mayer, Arizona, August 20.

The Editor:

Sir—A subscriber in San Salvador, asks in your August 12 issue for a portable library. The following list, though rudimentary, may start him on the right track as far as economy of space and weight are concerned:

Tracy's 'Plane Surveying.'

Trumbull's 'Underground Surveying.'

'Electrical Engineer's Handbook,' McGraw-Hill.

Croft's 'American Electrician's Handbook.'

Trautwine's 'C. E. Handbook.'

Spurr's (leather) 'Geology Applied to Mining.'

Miller's 'Prospector's Companion.'

ARDEN PROCTOR.

Englewood, N. J., August 31.

Signal Code for Surveying

The Editor:

Sir—During my experience as a field engineer and surveyor I have been surprised at the fact that there seems to be no simple and efficient wig-wag code in common use among engineers. There is, it is true, a generally recognized code of signals for the more common operations in the field, but a more elaborate system, which would cover any point which might arise, would result in the saving of much traveling and unnecessary work.

The wireless telephone is still out of the question, and the army and navy codes, while efficient, are too complicated. I have, therefore, devised a code, which, while comparatively slow, is efficient and may be learned in two hours practice at short distance.

In the starting position both hands rest on the breast and after each signal return to the same position. The different signals, corresponding to the illustrations, are 1, 2, 3, 4, 5, 6, 7, 8, 9, and 0, and are self explanatory. For the alphabet the numbers corresponding to the alphabetic positions of the letters are given; that is A-1, T-20, Z-26, etc. The letters are separated by a dip and the words by a rise, both of which are shown. The dip and rise also indicate that letters, and not numbers are being given. The signals are shown in the accompanying illustration, commencing with 1 at the left, the positions from start, rise, and dip being on the right.

Convenient practice may be had by two persons standing at opposite ends of a room and sending any copy, such as columns of figures, that may be at hand.

Cyanidation at the Comacaran Mine, Salvador

The Editor:

Sir—In reading Mr. C. O'Brien's criticism in the issue of July 1, I felt that it called for an answer. In his zeal to defend what he styles a C. C. D. system Mr. O'Brien makes statements that call for discussion. I am just as strong an exponent of the continuous counter-current decantation process as he is, but there is no machine or process that is faultless.

In the first paragraph of the criticism the question is asked why the tube-mills are by-passed. "why something is coming out and nothing is going in." The reply is that the arrow-head on the dotted line connecting the figure representing the tube-mills with that showing the Dorr duplex classifier was missed in the drawing. The capacity of the agitators is 120 tons each. The gravity sample of each slime-charge is screened, and only 5% of minus 80-mesh stays on 200-mesh. The brevity of my article did not permit giving the screen-tests and analyses asked for.

I must apologize for the annoyance the misuse of the word "insoluble" has caused Mr. O'Brien.

In the fourth paragraph of his article he desires to know the reason for the "juggling" of the solutions. This was necessary, as after a thorough trial of the straight C. C. D. system, it was found to be insufficient with the number of thickeners we had, and we were forced to use barren solution also. A glance at the Comacaran flow-sheet will show that thickeners 5, 6, and 7 are in a real counter-current system. Between 4 and 5 the system is changed. The overflow of 5, which assays 50c. per ton, goes to the battery solution-tank instead of to 4, whose pulp is diluted with the overflow from thickener 1, which assays \$1 per ton. The reason for this change is, that the dilution carried on in thickener 5 is so great that if the overflow were used in thickener 4 the zinc-box heads would be impoverished too much. Furthermore, this disposal of the overflow of 5 makes it possible to reduce the dissolved metal in the pulp from the thickener that precedes it, over two-thirds, while each of the thickeners in the real C. C. D. system reduces the dissolved value in the pulp from the thickener that

SIGNALS FOR SURVEYING.

precedes it only a half, due to the dependency of these thickeners on the capacity of the pumps and piping. These are the reasons for the juggling of the solutions.

Mr. O'Brien's exception to what I called a battery solution is well taken. The overflow of thickener 1 is not only the battery solution, but the solution from the closed grinding-circuit as well. But on looking at the flow-sheet and reading the paragraph entitled 'Tube-Milling and Classification,' it will be seen that a 30c. battery solution is fed to the stamps that crush to 3-mesh. The pulp from the batteries goes directly to the Dorr duplex classifier. I have not the assay-value of the solution coming from the stamps, but considering the size of the screens and the short time that the ore is in the mortar, it can be seen that the solution can be enriched little above its original 30c., and that this solution mixing with the much smaller quantity of solution from the closed grinding-circuit dilutes the latter and gives the \$1 overflow from thickener No. 1. So the grinding-circuit is safe from the ignominious fate of "dying of ennui."

In paragraph eight Mr. O'Brien at last finds something worthy of praise in a tailing-loss of 10c. in dissolved metal. The 0.8 lb. of cyanide lost in the tailing cannot be accredited to the C. C. D. system. It is one of the disadvantages of the use of barren solution. The loss in cyanide and dissolved metal in the tailing is now being recovered by the use of Oliver filters.

It cannot be said that the sticking of the thickeners at the Comacaran mill was due to abuse. The chief reason was that the bottoms were too flat for the density of the underflow sought. The rakes can handle only the small quantity of non-mobile material that forms on the bottom, as the slope of the bottom should be sufficient so that everything fluid enough to flow towards the centre can do so. It is obvious that a pulp containing but 25% of solid will not need as steep a slope as a pulp containing 60%. One of the home-made thickeners at the Comacaran has a bottom slope of 17° and will easily give an underflow containing 50% solid. The only time this thickener stuck was when a peon dropped a shovel into it. Another unavoidable source of sticking was due to hard material caving from the sides and from the spider supporting the rakes.

In paragraph ten of his article my critic makes the statement that the use of barren solution is unnecessary. The manner of reducing the value in intermittent or continuous decantation is one of pure dilution. If the overflow were used exclusively it would take twice or three times as many thickeners, for the simple reason that the dilution would be carried on with solution containing from 10c. to \$1 per ton. In other words, to save some 200 tons of "unnecessary" barren solution we would have to lock-up continually several hundred tons of low-grade solution. The barren solution used on the sand-vats was not accredited to the C. C. D. process.

I would like to ask my friend what the grinding-circuit has to do with the extraction of metals from the treated pulp. If the heads are doubled, the dissolved

value in the treated pulp will be doubled, if the grinding-circuit is not dying of ennui. Therefore the dilution in the thickeners will have to be doubled or else the dissolved metals in the tailing will be doubled.

A rather bold statement is made when Mr. O'Brien says that "neither crushing nor re-grinding takes place in the last four feet of a tube-mill." A tube-mill will grind its entire length. Of course, the grinding toward the discharge-end will not be nearly as great as it is near the feed-end. The reason for this is that as the ore becomes more comminuted on its way to the discharge a sludge is formed along the central axis that serves to cushion the blows of the pebbles. This is why it has been found that a 16-ft. tube-mill grinds more per horsepower than a 20-ft. mill, with a smaller pebble consumption. This sludge could be eliminated by making the last four feet of a 20-ft. tube a cone, and in this manner getting the grinding capacity of a 16-ft. tube with the rapid discharge of a Hardinge mill.

In closing permit me to say a few words in regard to the statement that "any American machinery is as good as Krupp machinery." I object to the word "any." The best American machinery is as good as the best of any land, but the American manufacturer should not think that Latin-American orders are opportunities to dump defective or inferior goods. They should bear in mind that representatives of foreign houses are in the countries, and ready to guarantee prompt and safe delivery of first-class goods at reasonable prices. Imagine our waiting for months for tube-mill lining from an American firm and then receiving lining from which must be cut an inch from each segment before it can be fitted. Imagine waiting a couple of months for a gasoline engine and receiving it with the cooling hopper broken, due to defective packing, and the induction-coil and batteries removed from their box. In the last case it was necessary to send to the States for an induction coil. The trouble seems to be that the American manufacturer has all the market he needs at home. Not until the domestic market becomes over-supplied, and the American manufacturer is forced to build-up a foreign trade or go bankrupt will he put the energy and brains into his foreign trade that the Europeans have put into theirs. In the meantime the American metallurgist in foreign lands will be forced into the apparently unpatriotic necessity of putting foreign-made machinery in American-owned mines and mills.

A. B. PECKHAM.

Quartz, California, August 8.

GOLD AND SILVER received at the San Francisco mint during August are reported as 365,087.75 oz. and 190,727.17 oz., respectively. Bars of fine gold, valued at \$4,191,916.21, were sold. Coinage amounted to \$620,000 in half eagles and \$27,000 in nickels; also \$17,000 in one and five centavo pieces for the Philippines. The vaults contain coin, bullion, etc., valued at \$378,767,597.52.

Atmospheric Decomposition of Cyanide Solutions

By G. H. Clevenger and Harry Morgan

INTRODUCTION. The losses of cyanide occurring during the treatment of gold and silver ores by the cyanide process may be classified as follows:

Chemical Losses:

1. Reactions with various constituents of the ore, including those introduced during its preparation for treatment.

2. Atmospheric decomposition through contact with the air, including hydrolysis.

3. Impurities in the water used.

4. Reactions occurring during precipitation.

5. Certain equipment of the plant with which the solutions may come in contact.

Mechanical Losses:

1. Admixture of solution with residues.

2. Leakage of tanks or other containers.

3. Excess solution sent to waste.

The relative importance of these various sources of loss varies considerably, depending upon the character of the ore treated, the plant, and the manner in which it is operated.

Atmospheric decomposition of dilute solutions has not been generally recognized as an important source of cyanide loss; therefore, practically nothing is known regarding its magnitude or the reactions involved. One of us (Clevenger) in 1909, while investigating the treatment of a certain Central American silver-gold ore, had his attention called to the possibility of the importance of such losses through observing that the cyanide consumption per ton of ore was greater when the mill was treating a small tonnage than when treating its maximum tonnage, the extraction of gold and silver in both cases being approximately the same. In seeking for the cause of this greater consumption, the most reasonable explanation appeared to be that, inasmuch as the tonnage of solution in circulation and in stock in each case remained the same, in treating the smaller tonnage of ore a relatively greater surface of solution was exposed to the air. The total atmospheric decomposition being the same in both cases, when distributed over fewer tons of ore would cause a higher consumption of cyanide per ton of ore treated.

In order to ascertain the loss of cyanide to be expected from this cause under the climatic conditions obtaining at this plant, a series of experiments was made in which solutions in glass beakers were left standing exposed to the air of the mill-office. These were titrated at regular intervals by the ordinary Liebig method without an

indicator. In each case distilled water was added to the beakers before making the titration to compensate for any decrease in volume caused by evaporation.

In series No. 1, the solutions were made of as nearly the same strength as possible from chemically pure potassium cyanide, commercial potassium cyanide, chemically pure sodium cyanide, and commercial sodium. These solutions were allowed to remain in open lipless beakers for a total period of 216 hours. Titrations were made at intervals of from one to two days. Table I shows the decrease in the cyanide strength for the various intervals.

TABLE I

Hours	Strength of Solution			
	KCN C.P.	KCN Com.	NaCN C.P.	NaCN Com.
0	0.217	0.223	0.201	0.222
48	0.116	0.159	0.138	0.151
72	0.082	0.126	0.119	0.128
96	0.027	0.085	0.083	0.087
144	0.010	0.015	0.029	0.019
216	trace	trace	trace	trace

After 216 hours the cyanide had entirely disappeared from all the solutions.

A similar series of tests was made with various makes of chemically pure cyanide, commercial cyanide with lead acetate, as well as 'milling' solution and 'barren' solution taken from the storage-tanks. Cyanide was determined by titration as before. The results of this series of tests are shown in Table II.

TABLE II

Hours	Strength of Solution					
	KCN C.P. Merck	NaCN C.P. Kahlbaum	KCN Com.	KCN C.P. E. & A.	NaCN C.P. Pb. Act.	Milling Sol. Barren Sol.
0	0.090	0.095	0.092	0.051	0.091	0.093
24	0.072	0.076	0.072	0.035	0.069	0.069
48	0.037	0.042	0.033	0.016	0.027	0.030
72	0.014	0.017	0.011	0.003	0.005	0.029
96	0.003	0.003	0.002	0.001	0.001	0.014
						0.023

These results confirm those previously obtained, with the exception that the milling and barren solutions from the mill show considerably less decomposition than the solutions made up from fresh cyanide to which no protective alkalinity had been added.

This points strongly to the fact that the double cyanides, particularly in the presence of protective alkalinity, are not as readily decomposed as the simple cyanides under the same conditions. This also helps to explain why it is that actual mill-results frequently show less cyanide consumption than is indicated by small-scale tests made with fresh solution.

In order to determine whether the decomposition was due to the air or to light, another series of tests was made employing a solution made from commercial cyanide. One-third of this was placed in an open beaker, one-third in a stoppered bottle that was protected from the light, and one-third in a stoppered bottle that was

¹The South African investigations had not been made at the time this was written. See M. & S. P., January 8, 1916.

exposed to the light. Titrations were made upon these solutions at the intervals noted. The results of this series are given in Table III:

TABLE III

Hours	Open Beaker KCN, %	Stopped Bottle KCN, %	Stopped Bottle in the Dark KCN, %
0	0.096	0.096	0.096
24	0.064	0.092	0.096
48	0.041	0.095	0.095
72	0.025	0.094	0.094
96	0.024	0.094	0.094
120	0.004	0.097	0.094
168	0.003	0.095	0.096
192	0.096	0.095

In the time generally required for cyanide treatment, light has practically no effect upon the decomposition of solutions of the concentration ordinarily used in mill practice.

At the time that these tests were made it was thought that the rapid decomposition indicated was due to the peculiar climatic conditions obtaining in Central America and that the decomposition would not be nearly so great in a temperate climate.

Some time ago Allan J. Clark² called the attention of one of us (G. H. C.) to a similar test made by him at the Homestake mine that showed substantially the same cyanide decomposition. He exposed 500 cc. of KCN and NaCN solution, to which had been added 0.05 grams of lime, to the air in shallow evaporating dishes. Titrations were made daily:

TABLE IV

Hours	Strength of Solution NaCN (in terms KCN),	KCN, %
0	0.25	0.593
24	0.21	0.169
48	0.133	0.095
72	0.058	0.020

The observations of Clark, together with those previously made by Clevenger, has led us to investigate the subject more fully.

The following statement regarding the decomposition of cyanide by air are to be found in current technology.

Thorp³ states that "dilute solutions of potassium or sodium cyanide decompose very slowly in contact with the atmosphere, the loss being almost wholly due to absorption of carbon-dioxide. Alkali cyanides yield ammonia and a formate when boiled with water."

Watt⁴ states that "aqueous solutions of potassium cyanide decompose in air, slowly at ordinary temperatures, rapidly at 100° C., giving potassium formate and ammonia."

Thorp⁵ states that the aqueous solution of potassium cyanide decomposes on standing or when warmed according to the following equation:

Allen⁶ states that potassium cyanide decomposes slowly in water, forming potassium carbonate, potassium formate, and ammonia.

Julian & Smar⁷ state that "even water decomposes single cyanides by hydrolytic action" * * * but "a

weak acid, such as carbonic acid, has a stronger action by thousands of times" * * * "Carbonic acid is absorbed by cyanide solutions from the atmosphere and, in absence of excess of free alkali, HCN is evolved. In moderately still air a square yard of surface absorbs 1000 cc. of CO₂ per hour and in a strong wind or by constantly stirring it absorbs 1200 to 1300 cc. per hour. The rate of absorption is hardly affected by the amount of alkali present within working limits but the tension of the CO₂ has a marked influence. The figures given refer to cases where the top of the tanks is several feet above ground level. But when the top of the tanks is on the level or below the level of the surrounding ground, the rate of absorption may be three or four times as fast. The presence of soluble and insoluble carbonates facilitates decomposition of cyanides."

In order to study the reactions taking place during the atmospheric decomposition of weak solutions of the alkaline cyanides, it became necessary to determine cyanide, cyanate, hydrate, carbonate, ammonia, and formate. The following methods for these determinations were used.

CYANIDE. (1) Liebig method.⁸ A 25 cc. sample of solution, to which two drops of KI had been added, was titrated with standard AgNO₃ solution to the first faint yellow opalescence. Titration of the solution without the addition of an indicator was used when zinc was present.

(2) Victor method.⁹ An excess of standard AgNO₃ solution (generally 10 cc.), together with 10 cc. of 1:1 HNO₃, was added to a 10 cc. sample of the solution contained in a 100 cc. volumetric flask. After diluting to the 100 cc. mark and filtering, the excess of silver nitrate in 50 cc. of filtrate was determined after the addition of 5 cc. of HNO₃ and 5 cc. ferric alum indicator by titration with standard potassium sulphocyanate solution (Volhard method).

Allen¹⁰ states that, unless the directions for performing this method are closely followed, unsatisfactory results may be obtained on account of the appreciable solubility of AgCN in dilute HNO₃. Our experience with this method is that, even when every precaution is taken, the results are generally slightly lower than those by the Liebig method.

CYANATE. Paterno and Pannin's method¹¹ for cyanate, hydrate, and carbonate is rather uncertain when applied to dilute solutions, on account of the behavior of silver cyanate.

Herting's¹² method for cyanate involves the conversion of the cyanate into an ammonia salt, followed by distillation with caustic soda. The NH₃, in the case of considerable amount of cyanate, may be collected in standard acid and determined by titration, while with small amounts of cyanate the NH₃ is collected in distilled water and determined by Nessler reagent. This

method was checked as follows: One tenth gram of Kahlbaum's C.P. potassium cyanate was dissolved in 50 cc. distilled water. 10 cc. of 1:1 HNO_3 was added to 10 cc. of this solution and evaporated to dryness. After taking up with distilled water, an excess of NaOH solution was added and the mixture distilled. The NH_3 was collected in distilled water and determined calorimetrically by Nessler reagent. The potassium cyanate calculated from the NH_3 found corresponded to 96% of the cyanate that had been added by weight. In view of the instability of the cyanates, this result is probably very close to the actual cyanate content. This method is open to the objection that it also indicates any ammonia salts present.

Bettel¹³ gives a method for determining NH_3 , involving the precipitation of cyanogen compounds, by a slight excess of AgNO_3 , precipitation of the excess AgNO_3 by a few drops of HCl and then distillation of the filtered solution with an excess of NaOH. The distillate is collected in distilled water and NH_3 estimated calorimetrically by Nessler reagent.

As there is no satisfactory method for the determination of cyanate in cyanide solutions in the presence of NH_3 , after considerable investigation based upon the work of Herting and Bettel, we developed the following method for the determination of nitrogen in dilute cyanide solutions in other forms than cyanide.

NITROGEN IN OTHER FORMS THAN CYANIDE. 10 cc. of standard AgNO_3 and 10 cc. of 1:1 HNO_3 were placed in a 100 cc. volumetric flask and 10 cc. of the cyanide solution to be analyzed added. The flask was filled with distilled water to the 100 cc. mark and, after shaking, filtered. The excess silver in 50 cc. of the filtrate was precipitated with NaCl and, after dilution to 100 cc., 50 cc. was distilled with an excess of NaOH. The NH_3 in the distillate was determined calorimetrically with Nessler reagent.

Two drops of phenol-phthalein were added to the samples after determining cyanide by the Liebig method and the alkalinity determined by titrating with standard oxalic acid solution. The above method of titration indicates one-half of the mono-carbonates present, as well as the alkaline hydrates. When soluble carbonates were present, they were first precipitated by the addition of $\text{Ba}(\text{NO}_3)_2$, filtration being unnecessary.

CARBONATES. The following method for carbonates is a slight modification of that given by Clennell.¹⁴

Ten cubic centimetres of a saturated solution of $\text{Ba}(\text{NO}_3)_2$ were added to a 25 cc. sample of the solution; after filtering and washing the precipitate, the moist filter-paper was placed in an Erlenmeyer flask, 10 cc. of $n/10$ HNO_3 added, and the filter-paper macerated; then titrated with $n/10$ NaOH, using two drops of methyl orange as an indicator. This method gives the carbonate, together with one-half of the bi-carbonate. It was checked upon a weighed quantity of dried C.P. potas-

sium carbonate and found to give the theoretical percentage of carbonate.

FORMATES AND ACETATES. Considerable difficulty is encountered in determining formates quantitatively in the presence of the other decomposition products of cyanide. However, there are a number of qualitative tests that are satisfactory. With cyanide solutions of the concentration and at the temperatures employed in these tests, it was impossible to detect either formates or acetates.

DECOMPOSITION TESTS IN OPEN BEAKERS. Atmospheric decomposition was investigated by exposing the various solutions to the air. Each solution was placed in an open glass beaker $5\frac{1}{2}$ in. diam. and $8\frac{1}{2}$ in. high; this filled the beaker to a depth of $6\frac{1}{4}$ in., as shown in Fig. 1. The beaker was placed in a room having good

FIG. 1. DETAIL OF BEAKERS USED FOR CONTAINING CYANIDE SOLUTIONS UNDERGOING ATMOSPHERIC DECOMPOSITION.

ventilation and entirely free from laboratory fumes. In each case, before removing the samples for analysis, the solution from the beaker was transferred to a graduated glass cylinder and the exact amount of distilled water added to compensate for evaporation.

Series A. 2000 cc. each of 0.1% and 0.2% solutions were prepared by weight from Merck's C.P. potassium cyanide. No alkali was added.

¹³Technical Analysis of Cyanide Working Solutions.' By W. Bettel. Proceedings of the Chemical and Metallurgical Society of South Africa. Vol. 1, p. 168.

¹⁴Chemistry of Cyanide Solutions.' By J. E. Clennell. P. 67.

It will be noted that a steady loss of cyanide is shown, but at not so rapid a rate as indicated by Tables I, II, and III. This is probably due to the fact that these tests were made in larger beakers and possibly to a less extent to the difference in climatic conditions between Central America and California.

Series B. 2000 cc. each of 0.10% and 0.40% cyanide solution were prepared by weight from Merck's C. P. potassium cyanide and distilled water. No alkali was added. Both cyanide and carbonate were determined at the intervals noted.

Cyanide was determined in this series by the Victor method. The results of Series B are shown graphically in Fig. 2.

Series C. Four portions of 2000 cc. each were prepared of 0.1% solution, employing Merck's C. P. potassium cyanide. The alkalinity was adjusted by varying the proportion of distilled water and lime-water used. One portion contained 80 points¹⁵ of alkalinity, one 40 points, one 20 points, and one 10 points. Cyanide, protective alkalinity, and nitrogen in other forms than cyanide were determined at the intervals noted.

The results of Series C are shown graphically in Fig. 3. This shows the effect of the alkali lime in lowering

¹⁵One hundred points of alkalinity correspond to a saturated solution of lime in water at ordinary temperatures; that is, 0.13%.

the rate of decomposition of the cyanide. It is to be noted that nitrogen in other forms than cyanide remains practically constant.

Series D. This series was the same as Series C, except that the solutions contained 0.20% cyanide:

The results of Series D are shown graphically in Fig. 4. This series confirms the results of Series C upon a solution of double the cyanide strength.

Series E. Two portions of 2000 cc. each of 0.2% solution were prepared, employing Merck's C. P. potassium cyanide. To one portion sufficient KOH was added to give 30 points of protective alkalinity; further additions were made every two days in order to maintain the alkalinity. To the other portion, 4 grams of C. P. K₂CO₃ was added at the beginning, but no later additions of K₂CO₃ were made.

8	66	0.180	82	2	0.116	42

NOTE. Cyanide was determined by the Liebig method.

The results of Series E, together with the curve for the decomposition of a 0.2% cyanide solution without alkalinity from Series B and the curve for the decomposition of a 0.2% cyanide solution having an initial alkalinity of 20 points of lime from Series D are shown graphically in Fig. 5.

It will be noted that the constant addition of an alkaline hydroxide makes for the lowest decomposition of cyanide.

Series F. In order to study the gaseous products of the atmospheric decomposition of cyanide solutions, the

apparatus shown in Fig. 6 was set up. *A* is an ordinary laboratory filter-pump; *B* a large glass bottle nearly filled with water, which, through the medium of an adjustable glass tube communicating with the outside air, acts as a pressure regulator; *C* is a Junker's gas meter for measuring the volume of air used; *D* and *E* are U-tubes containing 10% KOH solution; *F* is a U-tube containing concentrated H_2SO_4 ; *G* is a glass bottle containing cyanide solution over which the air is passed (detailed drawing of this bottle is shown in Fig. 7); *H* is a U-tube containing 10% KOH or distilled water, depending upon the test; *I* is a U-tube, not shown, containing 10% KOH, only used when the CO_2 was to be removed from the air before passing over the cyanide solution; *J* and *K* are wash-bottles containing concentrated sulphuric acid.

In tests No. 1 and 3 of Series F no alkali was added to the solution, nor no provision made for the removal of CO_2 from the air. It is of interest to note that a large proportion of the cyanide lost from the solution is recovered by absorption in an alkaline hydroxide solution. This indicates that the major portion of the decomposi-

tion involves the formation of HCN. Additional light is thrown upon the reactions taking place through the finding of NH_3 in the gaseous products of decomposition.

In test No. 4, CO_2 was removed from the air by passing it through a solution of KOH, but no alkali was added to the solution. In this test there was some carbon-

ate of ammonia formed, but the decomposition of cyanide was much less than in the absence of alkali when CO_2 was not removed from the air. In test No. 2, in which the CO_2 was removed from the air and alkali added to the solution, the cyanide decomposition is still less than in test No. 4. In test No. 5, the CO_2 was not removed from the air, but the solution contained a comparatively high alkalinity due to lime.

In test No. 6 both lime and zinc were present, so that this solution was similar to a mill solution. These two tests, while not for so long a period as the other tests, indicate the retardation in atmospheric decomposition possible if there be sufficient protective alkalinity present in the solution.

THE CHEMISTRY OF ATMOSPHERIC DECOMPOSITION. The chief products of atmospheric decomposition of weak cyanide solutions are:

FIG. 2. CURVES SHOWING LOSS OF KCN AND GAIN IN K_2CO_3 THROUGH ATMOSPHERIC DECOMPOSITION OF 0.10%, 0.20%, AND 0.40% KCN SOLUTIONS CONTAINING NO PROTECTIVE ALKALINITY.

FIG. 3. CURVES SHOWING THE INFLUENCE OF VARIOUS DEGREES OF PROTECTIVE ALKALINITY UPON THE ATMOSPHERIC DECOMPOSITION OF A 0.10% KCN SOLUTION.

(1) Alkaline carbonate, which remains in the solution as soluble sodium or potassium carbonate, depending upon which alkaline cyanide is used, in the absence of calcium hydroxide (lime); in the presence of calcium hydroxide, the carbonate is precipitated from solution as rapidly as formed as insoluble calcium carbonate.

(2) Hydrocyanic acid, which mostly passes off into the air as a gas unless there is an excess of alkaline hydroxide present.

(3) Ammonia, which also mostly passes off into the air as a gas.

Potassium cyanide¹⁶ in aqueous solution hydrolyses¹⁷ as shown by the below equation:

In this reaction, which is a balanced one, H_2O may be considered a weak acid, which, like any other acid, liberates a certain amount of acid (HCN in the form of gas in this case) from the KCN dissolved in it.

Hydrolysis proceeds until equilibrium is established for the particular concentration of cyanide in solution. Moir¹⁸ has published a table showing the hydrolysis of pure NaCN at a summer temperature (in South Africa); results are stated to be 10 to 15% lower in the winter. It will be noted from these figures that the hydrolysis becomes greater as the solution becomes more dilute.

Removal of KOH from the right of the equation causes the reaction to proceed in that direction until equilibrium is established. Consequently the addition of sufficient acid to the solution to combine with the KOH as rapidly as formed causes the hydrolysis to proceed until all the KCN has been converted into HCN.

Y = total cyanide as KCN.

X = portion hydrolyzed to HCN, but calculated as KCN.

Z = portion hydrolyzed to NaOH, calculated as NaOH.

¹⁶Throughout this discussion, for the sake of convenience, potassium cyanide is used as implying either sodium or potassium cyanide.

¹⁷The mechanism of the hydrolysis of KCN according to the ionic theory is as follows: "In aqueous solution potassium cyanide is ionized in the ordinary manner into K^+ and CN^- ions, but water itself is ionized to a certain extent ($\text{H}_2\text{O} \rightleftharpoons \text{H}^+ + \text{OH}^-$) and, as hydrogen cyanide is a very feeble acid and, therefore, ionized to only a very slight extent in aqueous solution, there

is a tendency for the H^+ ions of the water to combine with the CN^- ions from the cyanide, yielding undissociated HCN, the result is that the equilibrium ($\text{H}_2\text{O} \rightleftharpoons \text{H}^+ + \text{OH}^-$) is destroyed and more molecules of water are ionized, but this results in further combination between H^+ and CN^- ions and, by this means, an excess of OH^- over H^+ ions is produced and thus the alkaline reaction. The changes continue until ultimately an equilibrium is established between the KCN, CN, K, H, OH, HCN, and H_2O present."—Dictionary of Applied Chemistry, Thorpe, Vol. III, p. 74.

This is well illustrated by the fact that it is impossible to determine the degree of hydrolysis by direct titration of the KOH formed with a standard acid. Cyanide solutions invariably show an alkaline reaction with indicators such as phenol-phthalein, methyl orange, etc., on account of the alkaline hydroxide present by reason of hydrolysis. Upon the addition of standard acid, the alkaline hydroxide is neutralized and the equilibrium which previously existed is destroyed, so that more salt is hydrolyzed to restore the equilibrium. This continues until the point of neutrality is reached, when all the cyanide is decomposed.

Even a comparatively weak acid like H_2CO_3 will react with the caustic alkali added to cyanide solutions or formed through their hydrolysis. This is precisely the effect which the CO_2 in the air¹⁹ has upon a mill solution with which it comes in contact. Therefore, in the case of a mill-solution that contains no protective alkalinity, the HCN that may be lost through normal hydrolysis of the cyanide may be comparatively small but, if sufficient air is brought into contact with such a solution, a large proportion of the cyanide may be lost through progressive hydrolysis. It should be made clear in this connection that, while the ordinary titration as practised for determining the protective alkalinity of mill-solutions indicates one-half of the alkaline carbonates present in the solution, the carbonate thus indicated is not effective as a protection against atmospheric decomposition. Upon exposure to the air of a cyanide solution containing alkaline hydroxide, the protective alkalinity as determined by Clemmell's method decreases until a point is reached where practically no protective alkalinity is indicated. There is then a gradual increase in the protective alkalinity until all the cyanide has disappeared from solution. This is shown in Fig. 3 and 4, where calcium hydroxide (lime) was the protective alkali used. So long as any protective alkalinity remained, CaCO_3 was precipitated, hence carbonate was not indicated by the Clemmell titration, all the solution samples having been filtered before titration. The low point in the curves, therefore, indicates where all the alkaline hydroxide [$\text{Ca}(\text{OH})_2$] has disappeared from solution. The rise in the curves from this point is due to accumulation of soluble K_2CO_3 . Herein lies a danger (at first sight not apparent) in plants operating with a very low alkalinity, since all the lime in solution may have disappeared before the end of treatment and the protective alkalinity indicated may be entirely due to soluble alkaline carbonate, which does not afford protec-

tion against the CO_2 of the air—the most potent agent in atmospheric decomposition. In such cases carbonates should be removed from solution by $\text{Ba}(\text{NO}_3)_2$ before making the titration for protective alkalinity. This is not necessary in solutions containing lime, since CaCO_3 is as insoluble in cyanide mill solutions as BaCO_3 .

Referring again to the equation for the hydrolysis of KCN solution previously given, if KOH be added to the right of the equation the reaction proceeds to the left and hydrolysis is checked. Therefore, the greater the concentration of caustic alkali the less the hydrolysis. This is well shown by results published by Moir.²⁰ While a high protective alkalinity may be desirable from the standpoint of atmospheric decomposition, yet there are other considerations in cyanide practice that cannot be ignored. Lime is the most economical and, commonly, the most satisfactory alkali to use in cyanidation, but, on account of the low solubility of $\text{Ca}(\text{OH})_2$, the amount of lime that can be used effectively is limited. Furthermore, within the limits of the solubility of lime, a high alkalinity may cause an undue consumption of zinc, with its train of attendant evils. A comparatively low alkalinity gives the best extraction with many ores, so that, on the whole, the degree of alkalinity must be a matter of compromise.

Roughly speaking, the addition of alkali equal to $\frac{1}{10}$ of the cyanide causes the recovery of 90% of the lost cyanide.

Carbon dioxide may react directly with KCN according to the equation:

Whether this reaction plays a prominent part during atmospheric decomposition we are unable to say, since the final products of the reaction are the same as those resulting when the intermediate step of hydrolysis takes place. However, it seems probable that this reaction plays a minor part when very small amounts of CO_2 are involved, as in air.

Nitrogen in other forms than cyanide is indicated in all the solutions from series C, D, and E. Ammonia is

¹⁹Normal air contains 0.02% CO_2 .—"Dictionary of Applied Chemistry," Thorp.

²⁰'Loss of Cyanide and Value of Protective Alkalinity.' By James Moir. Jour. Chem. Met. & Min. Soc. of S. A., Vol. 16, p. 10.

indicated in the gaseous products of decomposition investigated in connection with the tests recorded under series F. It is a well known fact that nascent oxygen forms KCNO when brought in contact with KCN, as, for example, during the electrolysis²¹ of a cyanide solution when the oxygen evolved at the anode combines with the KCN to form KCNO. Our results indicate that the oxygen of the air reacts slowly with KCN, giving first KCNO according to the equation:

Masson and Masson²² state that KCNO decomposes in aqueous solution according to the equation:

Hamilton²³ states that KCNO decomposes in cyanide mill solutions according to the equations:

In the presence of KOH

In the presence of $\text{Ca}(\text{OH})_2$

The equations advanced by Hamilton harmonize with the finding of NH_3 in the gaseous products of decomposition. The nitrogen in other forms than alkaline cyanide found in the solutions after decompositions is due to undecomposed KCNO, an NH_3 salt in solution or $\text{CO}(\text{NH}_2)_2$ (urea).

SOUTH AFRICAN INVESTIGATION. When the European war threatened to interfere with the furnishing of an adequate supply of chemicals for the Rand, the Chamber of Mines made an appropriation for the study of cyanide losses. Experiments were made by C. A. Meiklejohn under the direction of a committee composed of W. A. Caldecott, K. G. Graham, E. H. Johnson, and H. A. White. An account of this investigation was published by H. A. White²⁴ in September 1915.

In the same journal, H. M. Leslie²⁵ published an account of his experiments. These two investigations cover a portion of the work done by us. Although our experimental work had been completed and this paper written, with the exception of the experiments recorded under series F, before the South African investigations were begun, it is of interest to note that the problem was attacked in the same general way, namely, by exposure of the solution in open containers to the air. The delay in presenting our results was occasioned by the exigencies of other work.

The portion of White's paper dealing with atmospheric decomposition may be summarized as follows: The first experiments were conducted in uniform glass jars holding about 300 cc., placed on a board above the sump. This gave a surface exposure of 84 sq. ft. per ton of solution as compared with 5 sq. ft. in a sump 6 ft. deep. No correction was made for evaporation, which would tend to cause the decomposition to appear less than it really was. The following conclusions are given as a result of these tests:

(1) Loose or incomplete covering is practically useless in preventing loss of alkali or cyanide.

(2) With weak solution no loss of HCN as total cyanide and but little loss as free cyanide occurs while available protective alkali is present.

(3) With strongest solutions the loss of HCN, both as free cyanide and total cyanide, becomes serious when available protective alkali is below 0.01% NaOH.

(4) Comparing results published by Williams (Jour. Met., Chem., & Min. S. of S. A., Vol. 4, p. 501), it is evident that the presence of zinc enormously decreases the loss of HCN by hydrolysis, etc.

(5) The recurrence of alkaline strength observed in experiment XXI was independently checked and can possibly be accounted for by change of KCN to K_2CO_3 .

Further experiments were run under varying conditions in both open and closed vessels. The following conclusions are drawn from these tests:

(1) The loss is incomparably greater in pure synthetic solutions, even with added alkali, than is the case with ordinary working solutions.

(2) Tables E, F, and M illustrate the very heavy loss shown in the presence of little or no protective alkali when determined with the addition of ferrocyanide. (This suggests that it is safer to omit the addition of ferrocyanide in working tests).

(3) In table G, the increased temperature effect is strikingly apparent, but alkali protection is low.

(4) Tables H, I, J, and K show the much improved results obtainable when the alkali strength (without ferrocyanide) is not allowed to get below 0.030% NaOH. The results shown in table C, where working conditions were attempted, more nearly indicate that decomposition is small as long as real protective alkali is present.

(5) In table L, the attempt was made to keep the alkaline strength up by daily additions of lime, but of course the drop during the 24 hours exposure could not be avoided.

If reference be made to Dr. Moir's valuable note (Jour. of Met. Chem., & Min. S. of S. A., Vol. 17, p. 9), it will be clear that the addition of alkali is of considerable benefit in reducing hydrolysis, which, however, is of secondary importance compared with the protection it gives against decomposition by atmospheric carbon dioxide, which is the principal source of the loss of HCN gas.

Leslie carried on exposure tests in both open and closed vessels from which he draws the following conclusions:

²¹The Electrolysis of Aqueous Solutions of the Simple Alkaline Cyanides.' By G. H. Cheever and M. L. Hall. Trans. Amer. Electrochem. Soc., Vol. 24, pp. 271-289.

²²Zeit. für Physik. Chem., Vol. 70, p. 290.

²³Proc. Chem. & Met. Soc. of S. A., Vol. 4, p. 357.

²⁴Cyanide Consumption on the Witwatersrand.' H. A. White. Jour. Met. Chem. & Min. Soc. of S. A., Vol. 16, pp. 24-26.

²⁵The Prevention of Hydrolysis in Cyanide Solutions.' H. M. Leslie. *Ibid.*, pp. 36-47.

(1) That simple cyanide solutions decompose by the hydrolysis of the solution.

(2) That the percentage loss by this reaction is greater in a given time, the weaker the solution.

(3) That increased temperature accelerates this decomposition.

(4) That the alkali formed as a product of the hydrolytic action has little or no protective action on the remaining cyanide, so that hydrolysis goes on until all the cyanide is destroyed.

(5) That the protection afforded by the addition of an excess of caustic alkali is by no means complete, and that the protection is only of a very temporary nature.

A small demonstration plant was used to ascertain this loss. This was capable of treating one ton of sand or 600 lb. slime at a time, and was so arranged that the whole cycle of the cyanide process could be carried out. Tests were made with both the open and closed systems. Cyanide consumption was found to be larger than in large-scale practice on the same ore. This is explained by small scale operation and the lack of protective paint on iron tanks.

The calculated saving at the Village Deep mill, if a closed system were used, is stated to be 50-60% of the cyanide used. Further tests made in small Brown agitators showed that with excessive air agitation, cyanide consumption was increased. Large-scale trials with working scale Brown agitators at the Modder B mine showed only a trace of cyanide saved. This was attributed to the high alkalinity of the cyanide solutions used, due to the use of zinc dust precipitation. The protective alkalinity was 0.0254%.

Taking up first White's paper: The effectiveness of loose or incomplete covering was not investigated by us, but the conclusion that loose or incomplete covering is not effective is what would be expected, since such covering would not prevent the circulation of the air and might in certain cases even promote it.

Our results regarding the effectiveness of protective alkalinity (alkaline hydroxides) and zinc are in a general way in accord with conclusions 2, 3, and 4; namely, that with sufficient protective alkalinity and a reasonable period of treatment the loss from atmospheric decomposition is not serious. The exact behavior of zinc is not clear, but the fact that mill solutions in general give lower cyanide consumption than fresh solutions in a general way confirms the conclusion reached under (4).

The "reemergence"^{22c} of the alkaline strength referred to under (5) and said to be possibly accounted for by the change of KCN to K_2CO_3 , we have definitely proved to be due to the accumulation of K_2CO_3 in the solution. This is well shown by our tests recorded under series C and D.

While doubtless it is true that the atmospheric decomposition of pure synthetic solutions is greater even when alkaline hydroxides are added, than with working

solutions, we cannot agree that it would be so great as the statement under (6) would indicate.

Under (7) it is suggested that it is safer to omit the addition of ferrocyanide previous to the determination of protective alkali. This suggestion is made on account of the fact that the ferrocyanide precipitates zinc with an accompanying increase in the alkalinity of the solution. The alkalinity thus indicated is not available for the protection of the cyanide.

Although the tests referred to under (8) are inconclusive and no special investigation was made of this point by ourselves, we are convinced that higher temperature causes increased decomposition of cyanide.

We are entirely in agreement with the statement under (9) that atmospheric decomposition is small so long as there is real protective alkalinity present.

The statement under (10) that hydrolysis is of secondary importance compared with the direct decomposition of cyanide by atmospheric carbon dioxide is not justified, since it is impossible to distinguish between this reaction and the one involving the intermediate step of hydrolysis, as the final products of the two reactions are the same. The important point to be borne in mind is that the CO_2 of the air removes the alkaline hydroxide as rapidly as formed by hydrolysis. Hydrolysis would stop as soon as equilibrium was established, provided that the alkaline hydroxide were not converted into carbonate. The rate of decomposition is therefore largely governed by the rate at which alkaline hydroxide is converted into carbonate. The other reactions, as our work shows, involving the decomposition of cyanide by the oxygen of the air, are of minor importance.

Taking up Leslie's paper:

Conclusion (1) may be passed as a general statement more or less in accord with our results.

Under (2), we are of the opinion that while it is true that the degree of hydrolysis is greater with a dilute solution, yet in the presence of protective alkalinity it does not work out this way in practice, for the reason, as previously pointed out, that the rate of decomposition is largely dependent upon the removal of protective alkalinity by the CO_2 of the air. It is a well known fact in mill-work that with sufficient protective alkalinity a weak solution shows less decomposition than a stronger solution, and for this reason as weak a solution as compatible with proper extraction should be used.

The conclusion under (3), that increased temperature accelerates decomposition is in accord with the conclusion of White and ourselves.

The statement under (4) that the alkali formed as a product of hydrolytic action has little or no protective action on the remaining cyanide is not true, only to the extent that the alkaline hydroxide is converted into carbonate. There is no distinction whatever between the alkaline hydroxide formed as a result of hydrolysis and that added; both are effective until rendered inert by the conversion into carbonate by CO_2 of the air, or for that matter, through various other reactions taking place during treatment which may convert it into inert salts.

^{22c}The breaking out again after temporary abatement or suppression. Usually said of something regarded as bad. A poor word to use in this connection, as the meaning is rather veiled.

The statement under (5) that the protection afforded by the addition of an excess of caustic alkali is by no means complete, and that the protection is only of a purely temporary nature would only be true when there was a very low alkalinity at the beginning and this is allowed to fall to the vanishing point or to the point where protective alkalinity again becomes apparent through the presence of carbonates. The results of the large-scale trials with working scale Brown agitators at the Modder B, in which only a trace of cyanide was saved, proves the contention of White and ourselves that sufficient alkaline hydroxide is quite effective in preventing undue atmospheric decomposition. The alkalinity of these solutions (0.0254%) would not be considered high in American practice (0.13% is a saturated solution of lime in water at ordinary temperatures).

IN MILL PRACTICE. The operator will naturally raise the following questions: (1) Is atmospheric decomposition of cyanide a serious factor in operating a cyanide plant? (2) What can be done to recover cyanide lost through atmospheric decomposition, and will it pay to recover it? (3) What can be done to prevent atmospheric decomposition?

These three questions which seem to cover the case fully can now be satisfactorily answered in the light of the South African investigations and our own investigation.

(1) Atmospheric decomposition may become a serious factor with cyanide solutions containing very little or no protective alkalinity, but when a reasonable protective alkalinity, due to alkaline hydroxides, is maintained throughout a reasonable period of treatment, the loss is not serious. When a long period is required, higher losses can be expected, therefore the aim should be to keep down the period of treatment to the lowest point compatible with a satisfactory extraction.

(2) The cyanide lost through reactions with oxygen cannot under any circumstance be economically recovered since the nitrogen is in the form of CNO (cyanate), $\text{NH}_2 \searrow \text{CO}$ (urea), and NH_3 (ammonia). Fortunately the decomposition due to oxygen under ordinary conditions of mill operation is small.

The cyanide lost through the reaction with CO_2 is in the form of HCN, which largely passes off with the air at the top of the treatment tank. This can be recovered by using closed tanks and passing all the air through scrubbing-towers containing lime-water or caustic soda solution, preferably the latter. In our opinion this would possibly only be profitable in the case of cyanide solutions containing little or no alkaline hydroxide.

Another alternative would be to pass the air used in agitation, or necessary in treatment, through a scrubbing-tower containing lime water or caustic soda, which would remove the CO_2 before introducing it into the treatment tank. In this case it would be necessary to cover the tanks in order to exclude outside air.

Still another possibility would be to connect the agitation tanks in such a way that the air introduced into the

first tank would pass through the whole series. A higher alkalinity could be maintained in the lowermost tanks of the series or the air could be discharged into a sump-solution having a high alkalinity. A system similar to the above was employed with the monteju used for agitation in some of the earlier filter-press plants operated in Australia, the air passing from one closed monteju to the next. In the one case with which we are familiar, there was a gain in cyanide strength toward the foot of the system. There are certain mechanical difficulties in applying this idea to agitation-tanks, since the pressure at the head would be considerable. One way of overcoming this, would be to draw air from tank to tank by special compressors. Increased pressures in the treatment-tanks would perhaps not be without its advantage, since there is evidence leading to the belief that with certain ores, at least, there would result a considerable acceleration in extraction.

(3) It will be obvious that the most effective method of preventing atmospheric decomposition is to maintain a sufficiently high concentration of alkaline hydroxides in the solution. In this connection we wish again to call attention to the fact that the method for the determination of protective alkali, as ordinarily practised, records one-half of the alkaline carbonate present and this is not effective for the protection of cyanide against atmospheric decomposition. When lime is not present in solution, carbonates should be removed before testing for protective alkalinity. Since the recovery of the cyanide requires the use of alkaline hydroxides, the most simple procedure is to add these directly to the solution, except possibly in those cases where a very low protective alkalinity is essential to the best extraction. In any event, the matter of alkalinity should not be over-done, since an excessively high alkalinity, while favorable to atmospheric decomposition, causes an undue consumption of zinc with its train of attendant evils. Like many other factors in cyanidation, the alkalinity should be a compromise to give the best all around results.

In conclusion we hope that some operator where the conditions seem to be favorable will make mill-tests upon the recovery of cyanide lost through atmospheric decomposition, and will publish his results for the benefit of others.

THE LEADING PORTS of the world are given by the *American Exporter* in the following order: New York, London, Hamburg, Antwerp, Liverpool, Marseilles, Havre, Bremen, Calcutta, Bombay, Buenos Aires. The foreign trade of New York during 1915 was \$2,125,000,000; that of London \$1,928,000,000. Hamburg's foreign trade in normal times is about that given above for London.

RAMM production in Bohemia, Austria, was 27.07 grains in 1915, valued at \$209,365. Compared with the 1914 yield there was a gain of 13.57 grains. Uraninite prepared for smelting amounted to 25,720 lb., worth \$471.50 per pound.

Agreement Between Minerals Separation and the Inspiration-Anaconda Companies

AGREEMENT made and entered into this — day of February one thousand nine hundred and fifteen by and between MINERALS SEPARATION, LIMITED, whose registered office is situated at 62 London Wall, London, England (hereinafter called the Licensors, which designation shall include its successors and assigns where the context so requires and admits) of the one part and INSPIRATION CONSOLIDATED COPPER COMPANY, a corporation organized and existing under the laws of the State of Maine and having an office at 42 Broadway, New York, N. Y. (hereinafter separately called Inspiration) and ANACONDA COPPER MINING COMPANY, a corporation organized and existing under the laws of the State of Montana and having an office at 42 Broadway, New York, N. Y. (hereinafter separately called Anaconda) of the other part.

WHEREAS a license agreement bearing date April 10, 1913, has been entered into by and between the Licensors and Inspiration and a license agreement bearing even date herewith has been entered into by Anaconda,

AND WHEREAS Inspiration and Anaconda are desirous of entering into a special agreement for a rate of royalty based upon total daily tonnages and are desirous of including certain additional companies hereinafter named for the purpose of increasing the total daily tonnage of material treated,

AND WHEREAS it has been agreed that Inspiration and Anaconda shall pay to the Licensors as a consideration for this agreement a guaranteed minimum royalty of three hundred thousand dollars (\$300,000) in the manner hereinafter set forth,

NOW THIS INDENTURE WITNESSETH that in consideration of the premises and the sum of one dollar by each of the parties hereto to the other in hand paid (the receipt whereof is hereby acknowledged) and of the royalties hereby reserved and of the covenants herein-after contained, it is hereby agreed as follows:

1. Inspiration and Anaconda in place of the royalties provided in clause "I" of each of the said license agreements, shall during the continuance of this agreement, for the purpose of ascertaining and determining the royalty to be paid, have and are hereby given the right of aggregating the total tonnage of copper ores treated by all flotation processes by all of the companies herein designated who shall have taken out Licenses pursuant to clause II thereof. Upon the basis of the aggregate tonnage so produced, it is agreed that the royalties to be paid shall be as follows:

At the rate of 12 cents for each short ton (2000 pounds dry weight) of ore treated when such tonnage does not exceed 4000 tons per day.

At the rate of 10 cents for each such ton of ore treated when such tonnage is more than 4000 tons and does not

exceed 6000 tons per day.

At the rate of 9 cents for each such ton of ore treated when such tonnage is more than 6000 tons but does not exceed 10,000 tons per day.

No charge shall be made nor any royalty paid for each such ton of ore treated over and above 10,000 tons and up to and including 15,000 of such tons per day.

At the rate of 8 cents per ton for each such ton of ore treated over and above 15,000 tons and up to and including 30,000 of such tons per day.

At the rate of 4 cents for each such ton of ore treated over and above 30,000 of such tons per day.

Such rate to be computed upon the total tonnage of material treated each day by Inspiration, Anaconda, and such others of the Companies hereinafter named as shall have had their daily tonnage brought within this agreement, by notification from Inspiration and Anaconda to the Licensors and shall have entered into license agreements with the Licensors as hereinafter provided.

For the purpose of arriving at the daily tonnage treated the total tons of material treated during each quarter shall be computed and divided by the number of days in each quarter except Sundays, and the result of such division shall be deemed to be the daily tonnage treated, the material treated by Inspiration and Anaconda and the other Companies named by all flotation processes to be included in such computation. Provided that such royalties shall be payable quarterly commencing on the first quarter day following the day and year first above written until the sum of \$300,000 shall have been paid, the payment of such sum being guaranteed by Inspiration and Anaconda jointly and severally, and such sum to be paid in any event regardless of the determination of the suit of the licensors and another against James M. Hyde which has been brought on a writ of certiorari to the Supreme Court of the United States, and regardless of the quantity of material treated; and further provided that if the total amount paid as royalties hereunder shall not have aggregated the sum of \$300,000 when the Supreme Court of the United States shall have passed finally upon the said case against said Hyde, Inspiration and Anaconda guarantee that they will within five days after having been notified of such decision by the Licensors pay the deficit, if any, between the total amount of royalties which shall have been paid to it and the sum of \$300,000; it being understood, however, that in the event of a deficit so occurring and Inspiration and Anaconda making the foregoing payment, that such payment shall be credited back as royalties upon the material if any, thereafter treated under this Agreement. If, prior to the decision of the Supreme Court of the United States in said case the total amount of royalties which shall have been paid under this agreement

shall have aggregated the sum of \$300,000, it is understood and agreed that if the Licensees continue to treat material under this Agreement royalties shall be paid as provided in the present clause of this Agreement.

The Licensors hereby consent that for the purpose of treating material by flotation processes, for which royalty has been agreed to be paid hereunder, the Inspiration and Anaconda may install at their own expense and use any apparatus they may choose.

II. Upon notification to the Licensors from Inspiration and Anaconda, the Licensors will enter into separate license agreements with any or all of the following named additional companies, such license agreements to be in the same form as the license agreement above referred to between the Licensors and Anaconda and at the same rate of royalty as is specified therein, said additional companies being as follows:

Greene Cananea Copper Company of Minnesota,
Cibola and Arizona Mining Co. of Arizona,
Arizona Copper Company Limited of Great Britain,
Consolidated Copper Mines Company.

Each of such additional companies and Inspiration shall within fifteen (15) days after each quarter day deliver its quarterly report of tonnages treated in duplicate to Anaconda and the Licensors, and thereupon the royalties on total tonnages shall be paid to the Licensors by Anaconda as above provided with a statement of the total tonnages treated.

III. On or before February 1, 1915, Inspiration shall pay to the Licensors all royalties due or which may be due up to and including December 31, 1914, under its existing license agreement above referred to at the rate of royalty specified therein, such royalty to be computed upon all material theretofore treated by flotation processes, and thereafter during the continuance of this agreement the payment of royalty by Inspiration and during the continuance of this agreement the payment of royalty by Anaconda shall be at the rate based upon daily tonnages and in the manner above particularly stated in Clause I of this agreement, except in so far as it is modified by Clause V of this agreement.

IV. This agreement shall continue until the determination in or dismissal from the Supreme Court of the United States of the aforesaid suit of the Licensors and another against James M. Hyde and until such time thereafter as may be taken by Inspiration and Anaconda for the exercise of the option hereinafter granted, and should such option be exercised favorably to the continuation of the Licenses above referred to, shall be further continued as hereinafter set forth.

V. Inspiration and Anaconda shall each have the option for the period of sixty (60) days after the determination or dismissal from the Supreme Court of the aforesaid suit to elect by notice in writing to the Licensors whether to continue the said license agreements or to terminate the same. Should they elect to continue the same Inspiration and Anaconda jointly and severally undertake and guarantee that royalties at the rates specified in Clause I of this agreement shall be paid upon at

least twenty-five million (25,000,000) tons of material treated from and after the day and year first above written and on or before November 6, 1923, and all of the license agreements above referred to shall be continued in accordance with the provisions thereof, royalties to be paid after payment of royalties under said guarantee for a minimum of 25,000,000 tons of material treated either at the special rate specified in Clause I of this agreement, or at the rates of royalty specified in said separate license agreements at the option of Inspiration and Anaconda, with the privilege to Inspiration and Anaconda to aggregate the total tonnages under all or so many as they may desire of said license agreements in the computation and payment of such royalties. Should Inspiration and Anaconda elect as above provided to terminate the said license agreements, this agreement and each and every of the said license agreements shall be thereby terminated, without prejudice, however, to the recovery by the Licensors of any money then already due or any right of action by reason thereof, and with full freedom to Inspiration and Anaconda and the additional licensees above named to contest the validity of the letters patent of the Licensors or the extent of the monopoly thereby granted and full freedom to the Licensors to enforce their letters patent against Inspiration, Anaconda and the above named additional companies, provided, however, that under such circumstances no patent claims for apparatus will be sued upon by the Licensors in so far as applicable to any apparatus installed while operating under said licenses.

VI. If at any time during the continuance of this agreement after the exercise of the option stated in Clause V of this agreement, by *force majeure*; strikes, general financial disturbances or unavoidable causes, Inspiration or Anaconda, shall find it necessary to temporarily stop or reduce its mining output so that a total average daily tonnage of 15,000 tons or more under this agreement is temporarily reduced below a daily average of 15,000 tons throughout a quarter, then for such period of forced reduced tonnage of material treated, royalty shall be paid at the rate of six cents (6c.) per ton in place of the higher rate provided for such lower tonnage in Clause I of this agreement, provided, however, that all tonnages treated and paid for under such special circumstances shall be excluded from and shall be additional to the guaranteed tonnage of 25,000,000 tons set forth in Clause V of this agreement.

VII. This agreement shall be construed in all respects and take effect as an agreement made in the State of New York and in accordance with the laws of the State of New York.

VIII. This agreement shall be assignable by Inspiration or Anaconda only as an entirety and only to its successor in its present business, and shall inure to and bind such successor or successors.

SIGNED SEALED AND DELIVERED by the parties hereto the day and year first above written.

MINERALS SEPARATION LIMITED,
By S. Gregory, Attorney.

Basic-Lined Copper Converters

*Probably the first attempt to use a converter lined with basic material was that by the late Charles F. Shelby at Cananea in 1907. He gave up the trial as impracticable. Some months later, Messrs. Pierce and Smith proved the basic lining a success at Baltimore and Garfield. From this time onward its use spread considerably, especially in the South-west. Magnesite brick is used in the basic-lined converter.

Operating data of basic-lined converters in the South-west are shown in the following table:

Air used per ton of iron slagged, cubic feet	212,502
Ore fed, tons	17,097
Ore fed per ton of matte blown, tons	0.200
Magnesite used for repairs	None

*Abstract from paper prepared for Arizona meeting of American Institute of Mining Engineers.

Manufacture of Electro-Chemical Products

The chief products made by the aid of the electric current are aluminum, phosphorus, silicon, sodium, graphite, chlorine, oxygen, hydrogen; ferro-alloys, copper, titanium, vanadium, and other alloys; calcium carbide, carborundum, and other abrasives; caustic soda, caustic potash, sodium, peroxide, chloride of lime or bleaching powder, carbon bisulphide and muriatic acid. According to a report issued by the U. S. Bureau of Census, the value of electro-chemical products has increased from \$18,450,000 in 1909 to \$29,600,000 in 1914.

This does not include iron and steel made in the electric furnace, which also falls under this class. The extent to which we are dependent on electro-chemical products is little realized. The manufacture of these products has been steadily increasing, but today the supply is far short of the demand, due, in many instances, to the inability to obtain permission from the Government to use more power at Niagara Falls, the great electro-chemical centre. Of 36 establishments reporting in 1914 manufacturing these products, 18 were in New York, 4 in Michigan, 3 in California, 2 each in Pennsylvania and West Virginia, and one each in several other States. Most of the plants in the State of New York are at or near Niagara. The 30th semi-annual convention of the American Electrochemical Society, whose membership includes the foremost electro-chemists of the World, will be held at New York, September 27 to 30, at the time of the Exposition of Chemical Industries.

In 1885 the United States produced 283 lb. of aluminum; in 1915 a total of 99,806,000 pounds.

Flotation Tribulations

By Jackson A. Pearce

Idaho Springs lies within a heavily mineralized district covering the better part of two counties, Clear Creek and Gilpin, in Colorado. Gold, silver, lead, copper, zinc, molybdenum, tungsten, and uranium in most of their manifold mineralogical forms, occur in commercial quantities. In the ores they occur individually and collectively, offering an excellent field for metallurgical research. Within easy reach of Denver with its milling machinery and of Golden, the seat of the Colorado School of Mines, this district is utilized as a testing yard for processes and machinery, falling intermediate between the laboratory and the modern plant. Thus it has become a museum of the world's metallurgical processes. One can find here almost anything from a long-tom to an electrolytic refinery.

Flotation, the most recent process to be placed on exhibition, had been in operation in a couple of local plants a few months before any decision had been made to install a machine at the Argo mill. Much laboratory work had been done on flotation, but as concentration and cyanidation had been running smoothly the desire to change was not burning. However, tests showed that it might be useful on certain low-grade silver ores not particularly well adapted to cyanidation. With this end in view a machine was installed.

Having dedicated the better part of my life to cyanidation, and having contributed largely to the adaptation of cyanidation to these ores, I entered upon flotation with many misgivings, and these few notes may be taken as a confession of a cyanider—not that of a flotation expert.

The preliminary tests were made in a home-made single-cell machine. Especial attention was given to an ore assaying 0.12 to 0.40 oz. gold, 8 to 20 oz. silver, and a strong trace each of copper, lead, and zinc. On account of its relatively high silver-value this ore is not particularly amenable to cyanidation. Although the gold in these ores yields readily to cyanidation the silver is backward, 60% being the average extraction. These tests were carried out with a view to establishing the best conditions as to speed of impellers, consistence of pulp, combination of oils, temperature, and fineness of ore. No critical condition was established in any of these lines, a satisfactory extraction, 85 to 90%, resulting from within wide limits of each. Other gold ores yielded a good extraction by flotation, but not sufficiently to enthrone one as to its preference to cyanidation.

A flotation machine of 100 tons capacity was installed to handle silver ores only, giving us two distinct flowsheets within the mill. The flotation system comprised stamping to 16-mesh, classifying in Dorr machines, concentrating on Card tables, re-grinding in a tube-mill, re-

concentrating on slime-tables, and thickening the combined slime and re-ground sand for flotation. With this arrangement we expected to get 55 to 65% extraction on the tables, and 50 to 60% on the flotation machine, or a mill extraction of 75 to 85%, which, considering the laboratory extraction of 85 to 90%, was a conservative estimate.

In the first three weeks of operation the extraction on the primary tables was 50%, but, contrary to expectation, the extraction in the flotation machine was nothing. Before table concentration this ore carried a trace each of galena, chalcopyrite, and blende, with sufficient pyrite to give a concentration ratio of 4:1. The exceedingly small amount of flotation-concentrate was composed of galena, chalcopyrite, and blende, with an abundance of silica but very little pyrite. The amount of this product was not sufficient to make an appreciable difference in the assays of feed and discharge. I may add that the assays covering this test averaged a shade higher for the discharge than for the feed. This was disconcerting, to put it mildly. Three weeks is not a long time in which to perfect a process, but it's a mighty long time to watch half the value of the ore going into the creek.

During this time we gave particular attention to oils. According to information gathered from reports, and from personal conversation with flotation metallurgists and salesmen, it seemed that the oil was the most important consideration in flotation. It is generally believed that different ores require different oils. Adjoining properties on the same ore deposit seem unable to use the same combination of oils. In this respect the outlook for flotation here was painful to consider, since this is a custom-mill fed by a multitude of mines in a district producing a great variety of ores. During the three weeks we made exhaustive tests, covering a wide range of oils, trying one after another, individually and in combinations. Operators seem to have favorite places in the system for feeding oils, some favoring the batteries, others the tube-mill, and so on, down to the last cell in the machine. We covered everything from the coarse crusher to the tail-race. Special mixers or emulsifiers are in common use, and we installed one. It seemed to make little difference what oil, how much, or where fed; the froth was always the same—abundant and barren. At times it was excellent to the view, according to one metallurgist, "a most beautiful froth," three to six inches deep, bluish black, and covering the entire froth-cell. At other times it was over-abundant, rolling over both ends, back and front of the machine, developing so rapidly that it required the best efforts of two men to sluice it to the creek. We ran it in this manner for 24

hours—not that we wanted the froth, but to ascertain the ratio of extraction to quantity of froth. Although the total amount of material floated was appreciable, there was no difference in assays of heading and tailing, clearly indicating non-selective action.

We used oils furnished by several companies, including crude wood-oils, pine-tar oils, tar, wood-cresote, crude and refined turpentine, asphalt, coal-tar, gasoline, coal-oil, gas-oil, crude oil, and coal-tar cresote.

Regular examination of the tailing showed pyrite in great plenty, every particle of which was thoroughly oiled, and easily floated from the gangue by simple panning. Was there some condition in the machine to disengage these oiled particles from the froth? Or, were they ever attached to the froth? Or to the bubbles preceding the froth? The machine was built with an intricate set of baffles following the agitation, through the tortuous course of which the bubbles might have dropped their burden. We simplified the baffles, trying a dozen different kinds, one after another, terminating a heart-breaking task with no baffles at all. The machine worked as well without as with baffles; so why baffles?

The mineral particles were well oiled, but lacked the balloon arrangement necessary to conduct them to the surface. Perhaps the agitators were not fast enough to churn the air into the oil. Most people emphasize the importance of peripheral speed, some giving 1500 ft. per minute as the best, extraction and power considered. We were operating at this speed, but increased it by stages to 2100 ft. The motor would not carry this load for more than a few hours at a time; besides, the results were no better than at 1500. We decreased the speed to 1200, and, finding it more economical in power and just as efficient in extraction, left it at that. Later on it was reduced to 1100. Turning our attention to ore-fineness we found a wide range of recommendations, some operators recommending—40, some—60, others—100, and yet others close to—200, nearly all contending that the finer the ore the better was the flotation. My own laboratory experiments on this particular ore gave good extractions on a 12-mesh product. We tried everything from a 16-mesh product direct from the stamps to a product 95% of which would pass a 200-mesh screen. While there were no encouraging signs within this range; the advantage, though small, lay with the coarser product.

During these tests (from January to March this year) the temperature hovered around zero, at times reaching 12 to 15° below. Mill-water was close to the freezing-point, and great care had to be exercised to prevent pipes and launders freezing. Although many consider higher temperatures, say 70° F., essential to good work, we were unable to attain this economically, for lack of facilities for returning the mill-water. Nevertheless, to satisfy ourselves on this point, we turned the full capacity of a boiler into the feed, thereby raising the temperature to 60° F. After six hours at this temperature the difference in effect was in no way sufficiently marked to justify heating.

Next we turned our attention to consistence, the general report favoring 6:1 for very fine pulp down to 3:1 for sand. We covered a range from 20:1 to 2½:1, coming to the conclusion we were nosing the wrong scent.

It might be assumed that inexperience in, or prejudice against, the process, to the one or the other of which most failures are due, was at the bottom of our troubles. While I have spent most of my life at cyanidation, and greatly value the process, and perhaps have a soft spot in my heart for it, the fear of failure in any undertaking greatly exceeds any prejudices I may have against it. Also, it may be said, we had the personal services of several distinguished flotation metallurgists, no one of whom was able to suggest any change leading to decided improvement.

It was the firm conviction of one engineer that the machine was over-loaded. Although it was carrying ¾ its rated load, I reduced the feed to 1/40 its rated capacity, not that we could expect to operate on that basis, but to get a clue if possible to the trouble. There was no improvement.

At last we did what at first we would have done with any other process: we investigated the theories. But with flotation, where everybody has gratifying success and nobody has a gratifying theory, it seemed unreasonable that we alone should need a theory. Theories of flotation are now running the gauntlet of thoughtful criticism so essential to the survival of the fittest. "Fittest" in this instance is not amiss, for almost all theories are limited to certain facts, and that theory survives or is accepted which is fittest, that is, which fits the greatest number or widest range of facts. The ionic theory of chemical reactions superseded the affinity theory by virtue of its being more inclusive. No sooner is a flotation theory advanced than there arises a brilliant array of facts tending to disprove it, or, in other words, to limiting its fitness, so that in the present state of the subject it ill becomes us dogmatically to assert that any one is the correct theory, exclusive of all others.

The early efforts to establish a theory involving adhesion, which is only a begging of the question, and one involving the angle of contact or angular hysteresis, have given way to those of more apparent merit involving occluded gases, electro-statics, and interfacial tension. Whether any one of these, or any combination of them, survives is problematical.

Regarding the application of the theory of angular hysteresis, we assumed that the pyrite was not making the desired angle of contact, and, knowing of no way to cause it to do so, we dismissed the subject.

THEORY OF OCCLUDED GAS. The theory of occluded gas so ably advanced by Durell appealed to me in its tangibility. All substances occlude gases, the tenacity of retention being more pronounced in some than in others, but in all cases capable of expulsion by osmotic pressure, increased temperature, or vacuum. Only by virtue of this occluded gas can a bubble of gas be attached to the substance. The sulphides of metals, iron, lead, zinc, etc., constituting the economic portion of the

ore are more tenacious in the retention of the occluded gas than silica, lime, feldspar, etc., constituting the waste portion of the ore. Therefore by regulating the osmotic pressure, temperature, or vacuum the occluded gases of the gangue-material can be expelled entirely, at the same time leaving sufficient gas in the sulphide to act as a nucleus in the formation of adhesive gas-bubbles, thereby giving us 'selective' flotation. Silica was coming over with the froth in preference to sulphides. The evident procedure was to expel the gas from the silica, taking care not to expel it from the sulphides.

We had already tried heat with no success; we were not prepared for trying vacuum; so we tried osmotic pressure. To increase the osmotic pressure, we increased

OIL-FEEDER AT ARGO MILL; ONE-THIRD ACTUAL SIZE. SPEED OF LARGE PULLEY 35 R.P.M.

the number of ions by the addition of some easily dissociated solute, say, sulphuric acid. Acid has the advantage over salts in its power to reduce the surface tension, or the 'surten,'* permitting the formation of bubbles. Starting with a very small amount of acid we increased it gradually to 20 lb. per ton. The more we added the more disheartened we became.

INTERFACIAL TENSION. Roughly stated, water and oil (if insoluble) in contact maintain their individual faces, the oil facing the water, the water facing the oil. This is the interface of the two. Now, introducing a solid, say, a small particle of ore, it is found to have three tendencies; it tends to enter the water only; it tends to enter the oil only; it tends to enter both oil and water. If the tendency to enter both water and oil is sufficiently marked for each liquid, it remains between the two, or on the interface, a phenomenon on which is based the theory of interfacial tension. This was wonderfully exemplified in our machine, the only drawback being that it was the silica that displayed a preference for the interface.

ELECTRO-STATIC THEORY. Gas and oil films are negatively charged irrespective of the electrolyte in which they are formed. Silica, and perhaps silicious gangue,

is negatively charged in the presence of the hydrogen ion, reversing its polarity in the presence of the hydroxyl ion. Sulphides are perhaps positively charged. The mutual attraction of oppositely-charged bodies together with the mutual repulsion of similarly-charged bodies operate to produce selective flotation.

On this assumption we examined the electrolyte: mill-water plus the soluble constituents of the ore. It carried copper and some iron and, among other things, a weak trace of acid. It would seem logical to acidify it more strongly to ensure a negatively-charged silica. But in acidifying to increase the osmotic pressure we observed that it improved neither the osmotic nor electro-static effect. Evidently the pyrite particles were not electrified, or else were unsuitably charged. We induced electrification, or tried to. By the hit or miss method we attempted to get an electrolyte that would make a more desirable distribution of the electric charges. We tried a long list of salts, acids, and bases, organic and inorganic. Nothing especially noteworthy resulted from these experiments.

By this time we had been operating or experimenting nearly three months, all the time at high tension. I had exhausted myself of ideas, likewise the entire mill-crew, and every visitor to the mill. I pressed everybody for suggestions, talked bubbles all day and dreamed bubbles all night. It certainly seemed that we had left nothing undone that should have been done. I must admit that the extraction had been improving gradually. The froth was making a better selection of material, but was still high in silica, voluminous and difficult to handle. Our endeavor was to produce less froth with more mineral, intensive as well as selective flotation. Exhausted of ideas, we drifted along a few days, when to our great surprise and for no apparent reason whatever, the froth so long sought appeared. The voluminous tough and silicious froth had given way to a thin heavily-laden froth with the greenish-yellow cast of the pyrite. Simultaneous with it the extraction went up and the silica down.

When the extraction increased to 92%, which exceeded our expectations, we felt more kindly toward flotation, even to the extent of trying it on ores that were being cyanided. For seven days we ran flotation and cyanidation side by side on the same ore with an extraction of 96.2% for cyanidation and 96.5% for flotation. This was a surprise from which we have not yet fully recovered.

Suspending cyanidation, we applied flotation to all the different ores we could muster to the mill. The results were so gratifying, cost and extraction considered, that cyanidation was abandoned.

For the four months ending July 31, the extraction by months has been 95.01, 95.06, 95.5, and 95.6%. Extraction by metals: gold, 97.35%; silver, 82.2%; copper, 93.1%; lead, the few assays would indicate about 95%; zinc, no assays. The extraction of the silver, though considerably higher than in cyanidation, is still unsatisfactorily low. This is contrary to the impression so gen-

*M. & S. P., July 29, 1916.

eral that because a mineral floats off the table it is amenable to flotation. Silver floats off the table to a greater extent than copper, yet the flotation machine removes a greater percentage of the copper than of the silver. Figures from four months operation show a recovery on tables, copper 64.3%, silver 63.9; on the flotation machine, copper 81.1%, silver 50.7%. This extraction by concentration and flotation compares favorably with the best cyanide practice under the most favorable conditions, and when viewed in the light of the wide range of ores treated it is surprising. I am including a table made from assays of lots sampled, giving a general idea of the range covered.

I have had a keen desire to know what was at the

ence, speed, baffle, though regularly we use no baffles, none of which interfered with the extraction, that is, noticeably so. The problem of going backward we found as difficult as previously it was to go forward, though beset with much less worry.

I believe that oil, temperature, speed, etc., each has its own influence on the extraction, but within wide limits can be measured in fractions of 1%. I believe our greatest trouble was due to accumulated slime—colloidal slime if you like. Tests not yet complete seem to show that not the absolute amount of slime, but the proportion of slime, is the disturbing element.

At present the salient features of the process are:

Ore: Pyritic, containing gold and silver, with small

No.	Gold, Oz.	Silver, Oz.	Copper, %	Lead, %	Gangue	Concentration ratio about	Remarks
1	0.14	1.84	..	2.0 ±	quartz	10 : 1	
2	0.18	11.60	trace	trace	feldspar	4 : 1	
3	2.50	7.50	2.0	1.5	quartz	3 : 1	Gray copper
4	1.72	6.88	3.0	..	feldspar	2 : 1	
5	0.74	0.58	quartz	40 : 1	Free milling
6	0.40	12.20	1.4	..	feldspar	12 : 1	20 years on dump
7	0.62	4.40	talc	10 : 1	40% saved on tables
8	2.06	0.40	none	none	quartz	2 : 1	
9	1.96	1.30	1.0	0.5	feldspar	5 : 1	Mostly free milling
10	1.05	20.50	1.9	8.0	quartz	3 : 1	Chalcopyrite

bottom of our three months' troubles, and to this end have carried on the operation under different conditions as to oil, temperature, consistence, etc. In practice we are using crude wood-creosote, 15%, and a Wyoming gas-oil, 85%, this being one of the best two combinations found in the laboratory tests. We ran 10 days on wood-tar oil and gas-oil; 10 days on crude turpentine mixed with coal-tar creosote; 2 days on pine-tar and creosote with gas-oil; 2 days on pine-oil with gas-oil; and 3 days on wood-creosote with coal-oil, in all cases getting the same high extraction. During our early efforts to find the right combination of oils we would make a mixture of this, that, and the other oil, try it for 12, 15, or 24 hours as indications suggested, and that not used in the trial was thrown into a slop-barrel. In this way we accumulated a barrel or so containing every conceivable oil on which we could lay hold, organic and mineral, with some organic acids, such as oleic. Running short of other oils one day, we had recourse to this slop, which proved as efficient, entirely so, as any other oil used.

As to temperature, one day during a particularly cold snap, we had occasion to stop the machine for a short time, during which ice of considerable thickness formed over the entire machine. When we started again it was necessary to break the ice to remove the froth, yet the froth was never more heavily laden with mineral than at that time.

To test the influence of consistence, we allowed the entire mill flow, battery-water, table wash, and all to run through the machine for three days. The oil consumption might have been heavier, but the extraction was not impaired.

Many other changes were made involving submerg

amounts each of copper, lead, and zinc, concentrating anywhere from 50:1 to 2:1.

Oil: Wood-creosote 15%, Wyoming gas-oil 85%. Much trouble was experienced in feeding the oil, due to the separation of tar, closing the openings of the vessels. To obviate this I devised a feeder with a rotating cylinder with impressed cups. One can be made easily by filling the central part of a plug-valve with metal and fixing with shaft as shown in sketch. This has been working quite satisfactorily.

Consistence: 4 or 6:1.

Temperature: That of the mill.

Screen test: minus 60. The grinding is more for the purpose of liberating the sulphides from the gangue than for preparing the liberated sulphides for flotation. The machine will handle a surprisingly coarse product if it follows good table concentration.

Speed: 1100 r.p.m.

No acids or other reagents are used.

The froth is small in volume, about $\frac{1}{2}$ in. thick, covering but one-third of the froth-cell. It is removed by revolving scrapers made of 20-mesh battery-screen. The screen-openings are small enough to prevent the froth passing back, but large enough to pass the slime, thus reducing the silica in the concentrate.

ELECTRICAL transmission in mine machine-shops is becoming more general on account of its flexibility, cleanliness, freedom from noise, efficiency, and economy. Most machines are fitted with individual motors, but care must be exercised in doing this, or the motor losses may become too heavy. It is often more economical to motor groups of machines on one shaft.

Mining Decisions

MINER'S LIEN—WATCHMAN, NOT ENTITLED TO

A person employed as a watchman and to collect accounts due a mining company is not entitled to a lien for his wages under the laws of Oklahoma.

Hunt v. Stirling (Oklahoma), 157 Pacific, 741. May 2, 1916.

CONVEYANCE BY CO-OWNER—FRAUD

A deed from a part-owner of mining property to his co-owner with whom he was on unfriendly terms, is not subject to rescission merely because the grantee concealed from the grantor results of development work that increased the speculative value of the property, but disclosed no new or different conditions from those already known to the grantor.

Richardson v. Heney (Arizona), 157 Pacific, 980. June 2, 1916.

OIL AND GAS LEASE—HELD MERE OPTION

An oil and gas lease providing royalties or rentals in lieu thereof was held to be a mere option where the lessee never went into possession of the land and void if no rights were exercised thereunder within a period of two years. A formal release by the lessee as a condition precedent to relief from liability for rentals was held unnecessary.

Morton v. Drosten (Missouri), 185 South-western, 733. May 2, 1916.

GAS LEASE—RENTALS IN LIEU OF DRILLING

A gas lease by its terms required the lessees either to drill wells and pay royalties on their output, or in lieu thereof to pay stipulated rentals. The lessees paid the rentals but failed to drill any wells. The territory having been proved through neighboring wells, the lessors brought suit for damages in the amount of loss in royalties resulting from the lessees' failure to drill and the consequent draining of the land through adjacent wells. Held, no recovery could be had. The covenant for rentals operated in satisfaction of all claims for royalties, the lessors having accepted the rentals tendered thereunder. The lessors' remedy for the lessees' failure to drill would have been to terminate the lease by forfeiture after due notice to commence work. Not having availed of that remedy, he cannot sue for damages.

Carper v. United Fuel Gas Co. (West Virginia), 89 South-eastern, 12. May 16, 1916.

BOUNDARIES—MEANDER RULE APPLICABLE TO MINING CLAIMS

The plat and field-notes on which a survey for a mineral patent was based are admissible in evidence to explain the descriptions in the patent. A meander line is a line run in the survey of particular portions of the public domain bordering on a stream or other body of water, not as a boundary of the tract surveyed, but for the purpose of defining the sinuosities of the bank of a shore of the water, and as a means of ascertaining the quantity of land within the surveyed area subject to sale. The shore or bank itself is the real boundary. This rule of meander lines is now held to apply to mining claims and the courses and distances shown in the patent of certain lode claims on the shore of Gastineau channel in Alaska were disregarded as fixing boundaries in favor of the actual line of ordinary high tide at date of survey. Land to the seaward of this line which has been filled in by artificial methods is not open to mineral location.

Alaska United Gold Mining Co. et al. v. Cincinnati-Alaska Mining Co. et al. (Land Department) Decision of Secretary of Interior, April 18, 1916. (Not yet reported.)

Book Reviews

CONCENTRATING ORES BY FLOTATION. By Theodore J. Hoover. Third edition. P. 320. Ill. index. *The Mining Magazine*, London, 1916. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$3.75.

In his preface to this imprint, which is 60 pages longer than the previous one, the author states that "the advance in the use of flotation processes has been remarkable, and a very considerable part of this advance has been due to the general diffusion of knowledge * * * by the circulation of the first and second editions." The text of the second edition has been re-published intact, even leaving, on page 190, the erroneous remarks concerning the flotation of bornite and chalcocite ores; likewise the measure of surface tension per "square" centimetre. The additional matter covers the period 1914-1916. In this, excessive attention seems to be given to the Everson patent. Brief mention is made of the status of pending litigation. The theories propounded on the electro-statics of flotation are deemed unsatisfactory, while a great deal of what has been written about viscosity is termed "nonsense." Discussing surface-films and contact-angles as investigated by G. D. Van Arsdale, Mr. Hoover states that H. L. Sulman and H. F. K. Pieard have for years studied this problem, and have voluminous notes ready for publication. These, however, are in the archives of the Minerals Separation company, who are acting as "censors." About this Mr. Hoover writes forcibly, advising the patent-owning company to be frank with its probable customers. Tabulated results are given of the Horwood and Lyster selective processes as used at Broken Hill. The Callow process, so extensively used in America, is given 4 pages, the M. S. 30 pages, all others 55 pages. An incomplete list is given of users of flotation systems. Out of an average of one patent per week during two years, Mr. Hoover says that "one gropes hungrily through this huge mass for a really new idea." He gives a list of the later patents. Certain gold ores in this country are now being treated by flotation on a large scale, yet the matter is dismissed in a few lines. The notes on oils and soluble frothing agents have been presented better in recent technical journals. Twenty-two pages are added to the previous 54 pages of bibliography, making the references fairly complete. In short, this is a reprint, without revision, of the previous edition, together with 60 pages of additional matter.

M. W. von B.

STEAM POWER. By C. F. Hirschfeld and T. C. Ulbricht. Third edition. P. 420. Ill. index. John Wiley & Sons, New York, 1916. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$2.

While essentially an elementary work on the steam engine and accessories, for colleges and technical schools, power-plant engineers will find it of value on many points. The matter is up to date, including as it does notes on the latest boilers, stokers, and turbines. The physical conceptions and units, and discussion on steam are well given. Various types of engines are described. Combustion is explained in a practical manner, also recovery of waste heat. The illustrations have been well selected. Altogether, the book will be found worth the price.

BOLETIN DEL PETROLEO. Organo de la Secretaría de Fomento. Office, 2 A Calle de Tequila No. 7, Mexico City. A. G. Perez, administrator. Price P18 per annum, or P10 per half-year. Issued twice a month. This is an official publication dealing with the oil industry of Mexico. The August number consists of 112 pages, with illustrations and statistical matter. Those interested in the work in the Tampico and Tuxpan districts will find some useful notes.

RECENT PATENTS

1,184,240. ORE CONCENTRATOR AND CLASSIFIER. Frederick N. Hubbell, San Francisco, Cal., assignor to David R. Carrier, San Francisco, Cal. Filed Sept. 8, 1914. Serial No. 860,802.

A classifier and concentrator comprising a shaking pan having a sloping bottom and side-walls forming a stratifying compartment and a plurality of collecting and discharging compartments beyond the stratifying compartment, the compartments being separated by transverse partitions, said partitions having ports at their lower ends, the vertical dimensions of said ports decreasing progressively away from the stratifying compartment, separate discharge conduits connected to the collecting compartments at progressively lower levels, and receiving means connected to each discharge means adapted to maintain a hydrostatic head in the conduits corresponding substantially to the hydrostatic head in the pan.

1,184,006. METHOD OF PURIFYING GAS. Carlton F. Moore, Salt Lake City, Utah, assignor to United States Smelting, Refining & Mining Company, a Corporation of Maine. Filed December 17, 1913. Serial No. 807,226.

1. The method of purifying the dust laden gases from ore treating and other furnaces which consists in passing the gases successively through a series of filtering fabrics, the final fabric of which is impregnated with dust preparatory to filtering use, and periodically removing the accumulation of dust from those fabrics only which precede the final fabric.

2. The method of purifying gases from ore treating the other furnaces to obtain an impurity free gas, comprising continuously passing the gases successively through a series of moveable filtering walls which become periodically impregnated and clogged with dust for removing the bulk of the dust and finally passing the gases through a quiescent dust impregnated filtering means for removing the last portion of dust.

1,192,731. RECOVERY OF NICKEL FROM ITS ORES. Henry Livingston Sulman and Hugh Fitzalis Kirkpatrick Picard, London, England, assignors to The Madagascar Minerals Syndicate, Limited, London, England. Filed Feb. 18, 1914. Serial No. 819,555.

1. The herein described process comprising precipitating nickel from a solution of nickel and other sulfates obtained by treating nickel silicate ores containing magnesium with sulfuric acid, crystallizing out a quantity of magnesium sulfate from the super-natant liquor, converting the magnesium sulfate into magnesium chlorid and a soluble sulfid,

dissolving the magnesium chlorid and the sulfid products in water, and adding the solution thus obtained to a fresh quantity of the solution of mixed sulfates, for the purpose described.

1,191,848. RABBLE-ARM. Harry H. Stout, New York, N. Y., assignor to General Chemical Company, New York, N. Y., a Corporation of New York. Filed Dec. 4, 1913. Serial No. 804,559.

1. In combination, a double-walled shaft, a rabble arm comprising external and internal pipes, the internal pipe being of a diameter greater than the radius of the external pipe and being located in and supported substantially along its entire length by the external pipe, the inner end of the internal pipe being connected with the inner wall of the double-walled shaft by a telescopic joint and the delivery end of the internal pipe being located adjacent to the outer end of the external pipe, and a stop to prevent outward movement of the internal pipe as a whole.

1,195,236. APPARATUS FOR RECOVERING QUICKSILVER FROM ITS ORE. William H. Landers, New Almaden, Cal., assignor of one-half interest to Pacific Foundry Company, San Francisco, Cal., a Corporation of California. Filed Mar. 29, 1916. Serial No. 87,618.

1. An apparatus of the character described, comprising a roasting furnace; a dust-settler with which the gas outlet from said furnace communicates; a condenser with which the dust-settler communicates; a stack to which the uncondensed gases from the condenser are delivered; means for subjecting the condenser to a cooling medium; and means for conducting the said medium with its absorbed heat, after it leaves the condenser, into the stack, to increase the draft through the apparatus.

1,194,669. CONCENTRATING RADIUM ORE. Herman Schlundt, Columbia, Mo. Filed Feb. 21, 1916. Serial No. 79,758.

1. The method of producing radium concentrates from carnotite ores and other suitable radium containing material, which comprises treating the material with a suitable solvent to dissolve the radium, together with barium, as sulfates, diluting the resulting solution and thereby precipitating the radium-barium sulfates in a finely divided condition in admixture with the undissolved material, and separating the

finely divided radium-barium sulfates by a differential sedimentation.

1,194,477. ORE-CONCENTRATOR. Louis David Chevalier and Henry Charles Reche, Dubuque, Iowa. Filed Dec. 27, 1915. Serial No. 68,791.

1. In an apparatus of the character described, an oscillatory reticulated table, means for forcing air upwardly through its reticulations and other means for creating opposed horizontal air currents over the upper surface thereof independent of those passing through the reticulations.

2. In an apparatus of the character described, an oscillatory table adapted to receive ore concentrates, separated means for forcing air currents vertically through said concentrates and also in opposed horizontal currents, independent of those which pass vertically through the concentrates, across its upper surface, and an inclosure for said table provided with an air delivery port.

1,195,424. FURNACE. Utley Wedge, Ardmore, Pa., assignor to The Furnace Patent Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Jan. 20, 1910. Serial No. 539,134. Renewed Jan. 20, 1916. Serial No. 73,210.

1. A roasting or like furnace having primary and secondary heating members, means for preventing flow of gas from one heating member to the other, means for effecting the discharge of gas from each member independently of the other and a mechanical conveyor for delivering a regulated supply of reagent to the material under treatment in the secondary heating member of the furnace.

2. A roasting or like furnace having a plurality of superposed hearths, one of the hearths in the upper portion of the furnace being chambered, means for admitting air to said chamber, and means for conveying the air heated in its passage through said chamber to a treating chamber in the lower portion of the furnace.

1,193,680. RECOVERY OF ZINC. Charles H. Fulton, Cleveland, Ohio, assignor to David B. Jones, Chicago, Ill. Substitute

application Serial No. 878,573, filed Dec. 24, 1914. This application filed Dec. 23, 1915. Serial No. 68,383.

1. The herein described method of recovering zinc from zinc-bearing ore, consisting of grinding and calcining the ore, mixing it with pulverized coke in quantity more than sufficient for the reduction of metallic oxides in the ore and with a carbonaceous binding material, forming said mixture into briquets under pressure, heating said briquets to a temperature sufficiently high to destructively distill and coke the carbonaceous binding material, but not high enough to volatilize the zinc content of the ore, to form a briquet capable of withstanding without disintegration zinc-distillation temperatures; and subsequently subjecting the briquets to the usual zinc distillation process to recover the zinc.

1,193,953. HYDRAULIC CONCENTRATOR OR CLASSIFIER. Frank F. Wagner, Denver, Colo. Filed June 29, 1915. Serial No. 36,918.

1. An hydraulic plant concentrator or classifier comprising a number of tanks disposed one above another and in communication with each other, each tank except the lowermost being open at the top for overflow purposes, hoods fitted over the top of the same and forming troughs for catching the overflow therefrom, the top of each hood being provided with an opening, means for connecting the lower extremity of the tank next above with said opening, an outlet connected with each hood, and a valve located in each outlet except the uppermost for regulating the discharge and for controlling the flow of water to the tank directly above.

1,183,172. PROCESS OF ROASTING ZINC-BLENDE. Charles A. H. de Saulles, New York, N. Y. Filed Oct. 17, 1914. Serial No. 867,047.

The method of treating zinc blende for recovering metallic zinc, which comprises roasting the blende, adding carbon to the roasting charge at the latter end of the roasting operation and regulating the air admission so as to produce a temperature not exceeding 1000° C. and thereby obtaining a reduction and dissociation of the sulfates present without volatilizing any of the metals, and finally treating the resultant roast in a suitable furnace to reduce the zinc to a metallic state.

1,195,655. TREATMENT OF ALUMITE AND THE LIKE. Howard F. Chappell, New York, N. Y., assignor to Mineral Products Corporation, New York, N. Y., a Corporation of Maine. Filed Sept. 23, 1913. Serial No. 791,288.

1. The process of treating alum, alum-stone, alum-rock and alunite, which comprises submitting the same, in a reducing atmosphere, to a temperature sufficient to convert substantially all of the potassium compounds contained therein into potassium sulfate, and substantially all of the aluminum compounds into insoluble aluminum oxide and thereupon lixiviating out the potassium sulfate; substantially as described.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

EFFECT OF POSSIBLE RAILROAD STRIKE.—WAGES.—TUOLUMNE, EAST BUTTE, BUTTE & SUPERIOR, DAVIS-DALY, ANACONDA.

Preparations have been made to operate all the mines as long as possible in case any threatened railroad strike eventuates. The Anaconda company transports its ore 28 miles by rail. With this company it is a question of bin capacity. Electric power generated by water is used, so that a shortage of coal would not affect operations seriously. At the present rate of production the bins would all be full in 48 hours. At the North Butte conditions are similar, save that hoisting with steam is done at one shaft and a supply of coal will have to be stored. The East Butte is dependent on the railroads for coal, and for limestone that is used for flux. There will be no difficulty in getting ore to the smelter, as it is only a few hundred feet from the shaft. The Elm Orlu mine of the Clark interests ships ore by rail to its concentrator, and could only work until the mine ore-bins became full. Steam power is used at the mine, and a shortage of coal would also cause a shut-down. At the Butte & Superior steam power is used only for hoisting. All the coal bins are kept full, and a large supply has been stored along the railroad track. The company sends its zinc concentrates to smelters in Kansas and Oklahoma. After the railroad cars on hand are loaded and the concentrate bins are full, the mill products will be stored as long as possible. In spite of all precautions it will be necessary to stop hoisting ore at most of the mines two days after any strike became effective, and within ten days all the mines here would be closed. Development and repair work could be done at those mines that are equipped with electric hoisting apparatus, or where a supply of coal is on hand, but no provision can be made to store ore after it is hoisted.

The pay-roll of the mining companies in Butte for August amounted to nearly \$2,500,000. Wages are paid on a sliding-scale, depending on the price of copper. When the average price for a month is above 25c. per pound the miners receive \$4.50 per day, and the office employees who get less than \$300 per month are granted an increase of 10% of their salaries.

The Tuolumne company has an option on the Butte Main Range property and has finished enlarging and re-timbering the shaft from the surface to the 700-ft. level. A narrow vein of high-grade copper ore has been opened. Shipments will be made to the Anaconda smelter, and until a railroad spur is built to the mine it will be necessary to haul the ore about one mile with teams or motor-trucks.

Developments in the lower levels of the East Butte are encouraging. The output has been steadily increased since the first of the year and the company has been earning a profit of \$200,000 per month. By January, 1917, there will be a surplus of \$2,000,000, and it is rumored that dividends will be started at the rate of \$2 per annum.

About 2000 tons of ore daily is being hoisted through the old shaft of the Butte & Superior. One of the new shafts is handling men and timber to the 1500-ft. level. A new steel head-frame 135 ft. high has been erected at this shaft and a large electric hoist is being put in place. Ore will be hoisted through this shaft in 7-ton skips by about January 1. New crushing equipment is being installed at this shaft, and when it is finished an accident in one shaft will not affect the production of zinc ore. A new dry, or chance-house, made of galvanized iron, has been erected near the new shaft.

Favorable developments at the Davis-Daly are attracting attention. The company is hoisting all the ore that the present equipment will handle, and the new hoist that is being installed will soon be ready. Davis-Daly owns the mineral rights to much of the ground on which the city of Butte is built. Recently a great many frame buildings were torn down to make room for more permanent structures, and excavation for the basements of these buildings have disclosed the apex of several veins, some of which warrant prospecting at depth.

The Anaconda company publishes a monthly magazine, called *The Anode*, that has for its object the fostering of a spirit of 'safety-first.' It is a difficult task to make a publication of this kind interesting, but with its articles, cartoons, and pictures the paper fulfills all requirements. The cartoons and pictures illustrate safe and unsafe methods of performing the various duties of miners. A prize is awarded each month for the best article submitted, and as a rule there are several good ones. Interest in the various first-aid teams is kept up by accounts of their performances and records of their contests. A prize of \$750 is awarded each year to the foreman who has the least number of accidents occurring to men under his charge. The publication shows in chart form how each foreman and his assistants are running. Diagrams give data on the accidents at all the reduction works that the company controls. *The Anode* fulfills a two-fold purpose: by avoiding accidents the miners are saved suffering and perhaps death, and the company saves money as nearly all of its employees come under the workmen's compensation act.

JOPLIN, MISSOURI

ZINC-LEAD ORE SITUATION.—SURPLUS STOCK OF CONCENTRATE.—DEVELOPMENT IN OKLAHOMA.—NEW MILLS.—CONVEYOR FOR TAILING.

Weak ore markets that put a decided check on the steadily increasing development of this district caused many mines to be closed and created a disturbing surplus of ore stocks held in local bins, is the disappointing record of the month of August. It may be said, also, that immediate prospects are not very encouraging. The average basis price for blende during the month was \$58.75. This is presumably about \$2 above the average settlement price, and when it is considered that the cost of wages, powder, and general mine supplies is much greater than formerly, and that many thin-ground mines have been opened, it is evident that many must be operating at a loss, or, at least, merely breaking even and continuing to operate only with the idea of keeping intact their working organizations, so as to be able to take advantage of better prices if they should come.

The biggest problem for local producers just now is the great surplus of zinc concentrate. This was variously estimated on the first of September at between 18,000 and 24,000 tons, the larger part of which is held in the Oklahoma portion of the region. This surplus has nearly all accumulated in the past seven weeks also, and comes not so much from increased production as from decreased buying. For several weeks some of the smelting companies have been out of the market altogether, while others have been purchasing only a small proportion of their ordinary demands. The menace of the surplus, which is greater than any previous one recorded in the region, became so oppressive that a meeting of mine operators

was called in the latter part of the month to meet at Webb City and discuss whether a general shut-down should be attempted. The meeting was well attended, there being representatives from most of the centres, but it was the general opinion that no united suspension should be tried, but that individual mine-owners who could do so without too great loss should close for the best interests of the district. Since this meeting a number of the larger mines have stopped work.

Unquestionably the lightest production for many years would now be recorded in this district, due to voluntary shut-downs, were it not for the wonderful development in the Oklahoma districts. Most of this work was begun early in the spring, when prices and prospects were exceptionally good, and there is no disposition to criticize the mine owners who are now adding so materially to the regional output, but it is a fact that it comes at an unfortunate time. The greater part of this large output comes from Picher and immediate vicinity. The Eagle-Picher Lead Co. has four mills producing large quantities of concentrate. The Netta, the latest of this company's mills to start, has a capacity of 1200 tons of ore in 20 hours, and the four plants are now yielding concentrate around 300 tons per week.—Just south of the Picher mines is a new centre called Century, which is the home of what is commonly conceded to be the most remarkable zinc mine yet opened in this field. It is owned principally by investors from Canada, and is known as the Montreal mine. A recovery of better than 75% blende was made from the first 1000 tons of ore mined, with only hand jigs for cleaning. Some 300 tons of free ore, with fragments ranging in size from that of a baseball to as large as a bucket, were taken out within two weeks after the orebody was cut in the first shaft.—A short distance from this remarkable mine the Lucky Kid company's new mill has just been placed in operation, and is making from 15 to 20 tons of concentrate daily.—Near it is the Underwriters Land Co., which has just started a new mill, and is making as high as 24 tons of concentrate per day.—The Admiralty Zinc Co., also in this new centre, has two mills at work, and will have a third going in a short time.—Across Tar creek, at Cardin, the Blue Goose and Beaver mines continue their remarkable production. These mines are owned by the Commerce Mining & Royalty Co., which has been holding for higher prices. At last reports there was 2500 tons of surplus in the bins at the Blue Goose and 1500 at the Beaver.—It is a safe estimate that the production of the Oklahoma section of the region has increased by one-fourth, and probably by one-half, in the past two months. So rich are so many of the properties that active drilling continues at a high rate, and more splendid prospects are being reported almost daily, despite the slump in general market conditions.

Continued dry weather has helped to keep production down. Half a dozen of the larger sheet-ground mines of West Joplin, with more than that number in the Prosperity section of Webb City-Carterville, have been unable to operate for several weeks owing to a lack of water for wet concentration. Among these plants are included the four properties of the A. W. C. Co. at Joplin, and the Tom Coyne and Lincoln Zinc Mining & Smelting Co.'s plants at Prosperity.

The most important new plant outside of the Oklahoma field is that of the Coahuila Mining Co., at Duenweg, Missouri. This company has built No. 3 mill just south of the No. 1, which is one of the largest in the district. Since it was started in the last week of August it has been treating 1800 tons of ore per day, and making more than a carload of concentrate. The plant is equipped with skips for hoisting, as is the No. 1 mill, and there are five 150-hp. boilers.

The A. R. G. company has completed a new 350-ton concentrating plant east of the Coahuila tract at Duenweg, but as yet has not been able to start it on account of lack of water.—The St. Regis company, which has just completed a new 300-ton mill at Chitwood, is experiencing the same difficulty, and is sinking its mill shaft in an effort to remedy the trouble.

The St. Regis No. 1 mill at Duenweg is operating at full capacity and making 120 tons of concentrate weekly.—The D. C. & E. company has started its No. 2 mill in the Oronogo bottoms north of Webb City. The mill has been built for 375 tons' capacity per shift, but in such a way that this quantity can be doubled later on.—The locally noted Cramer mill at Cave Springs has been sold and will be moved to a property near Miami.—The West Virginia company has re-built the old Durston plant at Galena and started working it once more.

For the first time in this district a belt-conveyor has been installed and worked. At the old Rabbittfoot property, west of Joplin, the Blatchley Mining Co. has been treating tailing and has not been able to get enough to keep its new mill busy. A steam-shovel was considered, but finally it decided on a belt-conveyor. It is a 16-in. belt, and carries its load 130 ft., and is able to deliver the tailing at the rate of 500 tons in 10 hours. An ordinary drag-scraper or skip, steam operated, is used to bring the tailing to the hopper under which the belt is loaded.

Although market conditions are not at all encouraging just now, few of the operators are really seriously discouraged. Profits during the winter and spring were greater than ever before, and a return to good conditions in the near future is generally expected.

TORONTO, ONTARIO

FOREST FIRES.—LABOR AT COBALT.—POWER FOR KIRKLAND LAKE.
NICKEL CONTROVERSY AND POLITICS.

Additional forest fires have been raging in Northern Ontario, resulting in further loss of life and property. The mining districts generally escaped, but the Casey-Cobalt plant was destroyed.

Serious disputes over wages and labor conditions at Cobalt, which have prevailed for some time, resulted in an appeal to the Canadian Department of Labor, which was asked to appoint a board of conciliation. This was found to be impracticable, owing to a want of organization among the mine-owners, which would have necessitated the appointment of a separate board for each mine involved. As an alternative, the Department has constituted a royal commission to enquire into a report on the questions at issue, consisting of Judge Coatsworth of Toronto, A. F. Corkill of Copper Cliff, and Joseph Gibbons of Toronto.

Development at Kirkland Lake is considerably hindered until electric power can be supplied by the Northern Ontario Light & Power Co. from Cobalt. This will not be before November. Production continues by steam power at the Tough Oakes, whose July gold yield was \$88,000 from 3700 tons. An ore-shoot 120 ft. long, of good grade, has been opened on a vein recently cut on the 200-ft. level.

The nickel question still occupies a large share of public attention. The result of a by-election in south-west Toronto, decided on August 21, is regarded as significant. After a hot campaign, in which the action of the Canadian and Ontario governments in permitting the export of nickel ore to be re-fined in the United States was made the leading issue, the Liberal candidate who opposed the Government mainly on this ground, was returned by a majority of 663, in a constituency which at the previous election went Conservative by a majority of 3763 votes. Public opinion has been greatly stirred up by the *Deutschland* affair, and the general belief is that her nickel cargo was the product of Canadian mines.

The Ontario government has given the British Canadian Nickel Co. a lease of water-power rights on the Wahnapiatae river for the purpose of developing electricity. The company, which owns a nickel mine at Copper Cliff, proposes to spend several million dollars in establishing a nickel refinery, using the electric smelting process.

A 150-ton mill is contemplated for the West Dome mine, where development has been very satisfactory.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

FAIRBANKS. On August 25 the Government held a land sale at Nenana. Fairbanks people purchased most of the lots. There were 133 lots sold, realizing \$100,600. Nenana will be an important station on the new railway.

JUNEAU. After returning to Boston from a recent trip to the Alaska Gold Mines property, the president, Charles Hayden, said, "summing the whole situation up, it is fair to say that the results up to date have been somewhat disappointing but viewing it in the light of the more perfect information we now have, the financing, development, and equipment of the property on its present showing and the present extent is fully justified from every view-point, and the same people who have been responsible for these things would do the same thing if they saw the property as they see it today, instead of as they saw it in the beginning."

The August output of the Alaska Gold Mines Co. was 169,000 tons averaging \$1.38 per ton. This compares with 150,493 tons of \$1.24 ore in July, and 164,800 tons of \$1.06 in June. Another locomotive is operating on No. 7 level. A larger proportion of ore has been available from No. 5 and 6 levels.

ARKANSAS

The mixture of carbonate and sulphide of zinc ores in the northern field has proved a nuisance, and treatment is difficult. A new process of separation, devised by J. R. Wilson of Marion, Kentucky, is now being tried.

ARIZONA

OATMAN. The Tom Reed company is to deepen its main winze from 1400 to 1700 ft. The large ore-shoot at the former depth is being stoped. The gold yield for August was \$65,000.

NEW BRIDGE OVER COLORADO RIVER NEAR NEEDLES, ON THE ROAD TO OATMAN.

At a depth of 58 ft. below the 200-ft. level of the Gold Key, a tole has been cut for 14 ft. averaging \$23 per ton. This mine is west of the Lexington, in the central part of the district.

The Nellie is being equipped with a compressor, engine, pump, and hoist.

MIAMI. During August the Inspiration treated approximately 490,000 tons of ore, yielding over 11,000,000 lb. of copper. Development was increased. Good progress is being

made on No. 6 level haulage drift, being driven toward the Joe Bush orebody.

The Miami Copper Co. has issued a statement covering the first half of 1916. Development covered 18,938 ft. In the Captain orebody the shrinkage-stope method has been most satisfactory. On the main orebody slicing has been started below the 420-ft. level block, ore being hoisted from the 570-ft. level. This method is also a success. The mill treated \$59,485 tons of ore averaging 2.086% copper, with 71.44% recovery. The 32,213 tons of concentrate assayed 41.8% metal. The gross copper output was 26,931,915 lb. In the plant three Chilean mills are to be replaced by two Hardinge ball-mills. With finer grinding and other improvements the monthly yield should be increased to 5,000,000 lb. Three Nordberg-Carels Freres Diesel engines of 1250-hp. each have been ordered. The cost of producing copper was 8.9526c. per lb. The profit was \$3,499,740, of which \$2,054,564 was paid in dividends.

MORENO. It is stated that I. W. W. agitators have made themselves a nuisance here recently by making foreign laborers commit acts of near violence.

CALIFORNIA

Under the auspices of the California Metal Producers' Association, assisted by the State Industrial Accident Commission and the U. S. Bureau of Mines, the second annual California field meet for miners was held at Sacramento on September 6. There were entered 9 first-aid teams and 3 mine-rescue teams, as follows: Argonaut Mining Co., Jackson, 1; Balaklala Consolidated Copper Co., Coram, 1; Empire Mines Co., Grass Valley, 1; Kennedy Mining & Milling Co., Martell, 1; Mammoth Copper Mining Co., Kennett (mine), 1; Mammoth Copper Mining Co., Kennett (smelter), 1; North Star Mines Co., Grass Valley, 2; North Star Mines Co., Nevada City, 1; and Plymouth Consolidated Gold Mines Co., Plymouth, 1 team. Also Empire Mines Co., 1; Mammoth Copper Mining Co., 1; and North Star Mines Co., 1 team.

In the first-aid contests there were three full-team, one one-man, and one two-man events. Positions in the first event were, 1 Kennedy, 2 Empire, 3 Argonaut, and 4 Mammoth. Prizes were gold medals, trophy cup and cap lamps, cap lamps, and books on first aid, respectively. In the one-man event the Mammoth captured \$10 cash and bronze badges.

The problem for the mine-rescue men was as follows: A 100-ft. tunnel, half open so that spectators could see the actions, the remainder closed, was filled with smoke and sulphur fume. The teams entered the deadly mixture, rescued a miner, emerged with him, and then gave him artificial respiration, etc. The positions were 1 Empire, 2 Mammoth, and 3 North Star. The prizes were gold medals, cup, and \$25 cash; \$25 cash, and first aid materials and bronze badges, respectively.

The contest director was Edwin Higgins, chief inspector of the Accident Commission. Prizes were awarded by the State mineralogist, F. McN. Hamilton.

ALLEGANY. Two new 5-stamp mills, one at old Tightner dump and the other at the Morning Glory mine, the latter financed by A. A. Codd of Nevada, have started crushing.

CARVILLE. On September 4 the Pacific Gold Dredging Co. launched a new boat on Coffee creek, 65 miles from Redding. The buckets are of 9-cu. ft. capacity.

GOLDSTONE. At Seebler Well, three miles away, a mill to treat Goldstone ore will be erected, a contract having been let for the first unit by M. Ballinger of Los Angeles.

GRASS VALLEY. The California mine, in the Rough and Ready district, has been purchased by K. C. Gillette for \$80,000. Machinery and lumber will be purchased. E. C. De Golyer is in charge.

JACKSON. The concrete tailing dam for the Argonaut company is finished. It is 500 ft. long, 40 ft. high, and has 13 arches, constructed on the Eastwood plan, somewhat similar to that of the Kennedy company.

NEVADA CITY. So that the sand and gravel in the South Yuba river near Humbug canyon may be washed, E. W. Kay and F. A. Elliot are to change the course of the river by carrying the water in flumes.

OROVILLE. At its Thermalito property the American Gold Dredging Co., late Oro, is to construct a new dredge. The company's other boats are some distance from this area.

(Special Correspondence).—Progress at the Old Eureka has been retarded during the past week on account of caves in the shaft, and the work of unwatering and re-timbering has reached a point only a short distance below the 600-ft. level. Little difficulty of this nature was encountered in the first 500 ft., most of the timbers being found intact; but notwithstanding the care now necessary to catch-up the loose ground, the management feels confident of reaching the 2000-ft. level early in 1917. The modern steel head-frame will have to be erected to continue exploration at depth, and grading is now being done for the concrete foundations of the new hoisting plant.

Amador county miners have evidently re-considered their threat to walk out on the 9th, as work at all the mines along the Lode continues as usual, and union officials state that they have no intention of declaring a strike.

With the exception of pumping operations, no work is in progress at the Rose or Poundstone mine a mile east of Sutter Creek. It is understood that negotiations are pending for a sale.

Sutter Creek, September 10.

COLORADO

BRECKENRIDGE. A recent transaction resulted in transferring 48 gold-bearing claims, including the Jumbo Extension, Double Extension, Mascot, Arab, Excelsior, and Dashwarren mines to Samuel Klaus of Boston. A 20-stamp mill was also part of the deal. To develop this ground the Pioncer Consolidated Mines Co. has been organized. The properties have been idle for several years. New machinery has been ordered.

(Special Correspondence).—The Roosevelt tunnel, which is being driven for the drainage of the Cripple Creek district, has now reached a point about 1290 ft. east of the Elkton main shaft. It is a little over 4 miles long to this point and 1800 ft. below the surface. The adit is about 9 ft. wide by 8 ft. high in the clear, with a ditch at one side 4 ft. wide by 2 ft. deep in the centre. During August the progress in driving was 437 lineal feet. The best previous record was 400 ft., in January 1909. During August only 27 days of 3 shifts each were worked, 8 men on each shift. The rock is a very hard volcanic breccia, with occasional dykes of phonolite and basalt, also very hard. It usually requires at least 30 holes to break a round, and 5 to 7 ft. per round is broken. Water is coming out of every fissure and crevice in the rock, and the total flow at the portal is now 10,350 gal. per minute. The men all have to wear heavy rubber clothing and boots. Little timbering is required. The rock is hauled from face by mules, and hoisted out of the Elkton shaft. The drills used are the Ingersoll-Leyner model No. 18 with 2½ in. bits for starters. Two drills on a horizontal bar are used each shift. The wedge-cut system of holes is drilled. It is intended to drive the tunnel about 6400 ft. farther to connect with the Golden Cycle shaft. The tunnel is now rapidly draining the entire district. Charles F. Fuller, a man of extensive and successful experience in tunneling, is superintendent of the work, and he has selected a

force of skilled workmen. T. R. Countryman is engineer in charge.

Cripple Creek, September 2.

GEORGETOWN. Hanson & Walthers, lessees at the Capital mine, have opened ore assaying 1190.4 oz. gold per ton. This shoot is 297 ft. above the main adit-level, and at a depth of 1200 feet.

LEADVILLE. This town has now a population of 8000, and 14,000 in the whole district, an increase of 500 in a year.

At the Western Zinc Oxide plant, where carbonate ore is treated, four new furnaces are in operation, making twelve. The plant's capacity is now 60 tons daily. Mines sending low-grade ore to the works are the Tip Top, Baby, La Plata, Robert E. Lee, Little Silver, Yak tunnel, and others. The weekly output is 50 tons of oxide containing up to 80% zinc. This will soon be 75 tons.

Ore assaying 165 oz. gold per ton has been found by Mock and Hartman in the Twin Lakes district.

TELLURIDE. Shipments of ore and concentrate during August totaled 129 carloads, mostly the latter product. This was a good month. Contributors were the Tomboy, Smuggler-Union, and Liberty Bell.

IDAHO

ADAIR. Shipments from the Richmond mine, near here, suspended last December, have been resumed, and two four-horse teams now are hauling ore to the railway at Saltese, Montana, 5½ miles away. Only the ore extracted in development is being forwarded, and two grades are being mined; the second class, averaging between 5 and 6% copper and \$10 per ton in gold, being sent to the Washoe smelter at Butte, and the high grade, running 20% copper, is going to the smelter at Greenwood, B. C. From 15 to 20 men have been employed since the beginning of the year. A fair tonnage of ore is blocked out. Charles Heidenrich is manager.

Arco. Owing to disappointing developments the Wilbert Mining Co., operating 40 miles away in the Dome district, has suspended milling. Exploration is to continue.

GEM. According to rumors circulating both at Spokane and in the Coeur d'Alene, the Tamarack & Custer Mining Co. has purchased the Frisco mill, near Gem, from the Federal company, and will take possession at once. No authoritative confirmation of the report is obtainable from either the Federal or the Tamarack & Custer managements, but the belief prevails generally that the deal, pending for several weeks, has been closed. To connect the Tamarack & Custer workings with the Frisco mill a three-mile aerial tram, traversing the divide between Nine-Mile and Canyon creeks, will have to be installed. It is said that plans for the carrier already are prepared, and that construction can begin as soon as material is assembled.

GLADSTONE. The Pittsburg-Idaho company is again paying 1½c. quarterly per share. This is equal to \$40,000. The monthly output of ore and concentrate is 2500 tons. A power-plant is to be erected.

GOLDEN. Portland, Oregon, people, headed by A. McRae, have bonded the Buckhorn mine in the Ten Mile district for \$100,000. An examination revealed 50,000 tons of \$15 ore. Development is done by four adits. The mill is to be re-modeled.

MURRAY. The placer areas adjacent to Murray are to be re-worked, after being idle for 25 years, by the Coeur d'Alene Placer Mining Co., which owns 2800 acres on Prichard creek. A dredge may be built next spring. J. S. Wyatt is in charge. Drilling is now under way.

MISSOURI

JOPLIN. At M. L. Smith's farm near Galena a drill is to prospect to a depth of 1000 ft. If ore is found there it will be the deepest in the zinc-lead region.

Ore prices were \$5 per ton weaker last week. The output

of the region was 5663 tons of blende, 211 tons of calamine, and 1180 tons of lead, averaging \$58, \$41, and \$64 per ton, respectively. The total value was \$415,100.

MONTANA

BUTTE. Work has been started at the Butte-Daluth mine, in charge of H. A. Frank.

MARYSVILLE. During August the Barnes-King properties yielded gold worth \$33,000 from 3511 tons of ore. The Riblet aerial tram, about three miles long, of 350 tons daily capacity, is working well. This carries loaded buckets up a steep incline a mile in length, and then down the remainder of the distance to the Piegian-Gloster mill.

PHILIPSBURG. Work has been resumed at the Swastika copper mine, which was closed two years ago.

NEVADA

ELY. The Coppermines company's Giroux mill at Kimberly is to be re-modeled, a contract having been let for this work. The Callow flotation system will be used in the 500-ton plant. Milling may start in three months. The Morris shaft is to be unwatered and sunk 250 ft. G. N. P. Douglass is superintendent.

GOLDFIELD. The Klondyke-Portland Mines Co. is to resume work at its property midway between Goldfield and Tonopah. Two carloads of silver-gold ore are ready for shipment.

LAS VEGAS. To handle ore from Goodsprings and other districts, J. B. Jensen is to build a sampler at Jean or Las Vegas.

(Special Correspondence.)—Pending installation of additional equipment to settle and filter the concentrate, the use of flotation has been temporarily discontinued at the Goldfield Consolidated mill. Changes in the ore must also be considered. Until more equipment is installed the company will revert to the cyanide process. It is believed that the company will be able to resume the use of flotation within 60 to 90 days. The process is entirely satisfactory on these gold-copper ores.

The west cross-cut from the 1750-ft. level of the Atlanta has entered the Consolidated lode, and is advancing in quartz assaying low in gold, silver, and copper. The work is being done in hopes of intersecting a shoot of \$30 to \$70 ore opened several months ago on the 1500-ft. level of the Grizzly Bear mine.

The Cuprite district reports considerable activity. At a depth of 300 ft. in the Rea copper mine a cross-cut is being driven to intersect the large vein disclosed at 200 ft. The mine is operated under option by W. A. Clark of Montana. —The Cuprite Sulphur Co. is shipping high-grade sulphur, and has contracted to produce a minimum of 200 tons monthly. A. W. L. Dunn is manager.

Goldfield, September 9.

NATIONAL. The National Mines Co. is to sink its shaft 500 ft. below No. 5 adit. This will result in opening the orebodies at depth and enable work to be done more economically.

NEW MEXICO

MAGDALENA. The plant of the Ozark Smelting & Mining Co. on the Graphic mine was recently destroyed by fire. Rebuilding will commence as soon as possible. Treatment was described by Philip Argall in this journal of January 22, 1916.

(Special Correspondence.)—The clean-up by the Mogollon Mines Co. for last half of August produced $\frac{3}{4}$ of a ton of gold and silver bullion and $4\frac{1}{2}$ tons of high-grade concentrate from the treatment of approximately 2100 tons of ore. The new shaft is 880 ft. deep, and has encountered andesite on both walls. Work on the company flume to convey tailing to storage-dams on Mineral creek, about 4 miles below, is being pushed and with prompt lumber deliveries will be completed this fall.

The tailing-disposal system adopted by the Socorro Mining & Milling Co., consisting of an elevator by which the mill dis-

charge will be conveyed to an adjoining flat, has been delayed by the equipment having gone astray in transit.

The Oaks Company is continuing to find good milling ore from development both in Clifton and Eberle mines, and is making regular shipments to local custom works.

The U. S. Geological Survey, through Henry G. Ferguson, is about to complete data for a geological folio of the district. A detail survey was made a few months ago, and Mr. Ferguson is now working on the geology of the properties. When completed this data will be of great value to the district.

Mogollon, September 5.

OKLAHOMA

BAXTER. Five miles west of this place, which is on the Kansas-Oklahoma line, the Blue Mound Mining Co. has put down 33 drill-holes, 23 of which in a space 500 by 600 ft., cut ore containing from 10 to 35% zinc-blende. The holes are from 204 to 280 ft. deep. Four shafts are to be sunk. The United Iron Works is to build a 400-ton mill, etc., costing \$50,000. The Eagle-Picher Lead Co.'s property adjoins.

TEXAS

(Special Correspondence.)—The West Texas Sulphur Co., which is composed of New Orleans, Louisiana, men, is preparing to exploit extensively the large sulphur deposit in the Toyah district that it acquired some time ago. The company's holdings embrace 600 acres, and a number of test holes show that sulphur occurs from the surface outcrop to a depth of about 75 ft. The product is high grade and can be easily mined, it is claimed. The Michigan Sulphur & Oil Co., which owns a large sulphur deposit in Culberson county, in the same section as that of the West Texas company, recently installed the first unit of a large sulphur reduction plant, and it is now producing and shipping considerable quantities of the product. A party of Mobile, Alabama, men, headed by F. H. Edington, recently visited this section and made an inspection of the different sulphur deposits with the view of becoming financially interested in the industry.

Toyah, August 25.

UTAH

There are 114 mining districts in this State, according to the U. S. Surveyor General's report for the past fiscal year. In these there are 37 mineral surveyors. During the period there were 31 mineral surveys embracing 151 locations. The demand for surveys of claims has increased greatly in the past 18 months. The cost per location was \$18.40.

To relieve the congestion of ore at Utah smelters the A. S. & R. Co. is to double its plant at Garfield, making 800 tons' capacity per day of copper ore. To take care of lead-silver ore the Murray smelter will be enlarged, and a 450-ft. stack built.

EUREKA. V. Carlson and H. Backman, lessees on the 1400-ft. level of the Gemini mine, are shipping ore containing from 500 to 7000 oz. silver, 20 to 30% lead, and 7 to 10% copper.

GARFIELD. The new sulphuric acid plant at the A. S. & R. smelter is making good progress and should be completed by November.

PARK CITY. The Big Four Exploration Co., treating tailing on Atkinson flat, will soon be working 800 tons daily. The zinc product has been sold up to the end of this year.

On October 2 the Judge Mining & Smelting Company pays 25c. per share, equal to \$120,000. This makes \$310,000 for the year. Good progress is reported from the new smelter that is to treat 40 tons of 40% zinc ore daily.

SALT LAKE CITY. Another ore-sampling plant is to be erected here. Mining interests that produce from 12,000 to 15,000 tons of ore per month are behind the project. The plant, of the Vezin type, will handle 750 tons daily, costing \$75,000.

The Ohio Copper company's property has been leased to the General Exploration Company.

WASHINGTON

Eleven mines in Stevens and six in Ferry county are now shipping ore to the Trail smelter in British Columbia. The Deer Trail, 22 miles from Davenport, is a new producer, although years ago it yielded \$750,000. The Last Chance at Republic is to be opened to a depth of 500 ft., and will be an addition to the shipping list.

The Conconully and Ruby mining districts are in the north-central part of Washington, about 40 miles south of the Canadian border. The ore deposits were discovered in 1886, but production has been small owing to lack of transportation

THE CONCONULLY AND RUBY DISTRICTS ARE SHOWN BY THE BLACK SQUARE.

facilities, difficulty in treating complex ores, and the decline in the price of silver. The most valuable ore deposits in these districts consist of quartz vein which occur in schists near the areas of granite or at the contact of schist and granite. The ore minerals, pyrite, zinc-blende, chalcopryite, and gray copper, carry silver and a little gold. A report on these districts, by Edward L. Jones, Jr., just published by the U. S. Geological Survey as Bulletin 640-B, contains a study of the geology and mineralogy of the region and detailed descriptions of the individual mines and prospects.

CANADA

BRITISH COLUMBIA

During the last week of August the Trail smelter received 15,134 tons of ore from all parts, compared with 11,487 tons in the previous week.

According to F. M. Sylvester of the Granby Consolidated, the company is always on the lookout for promising new properties. In the past year about 100 prospects were examined. Of the newer properties two now are on a substantial producing basis. The Midas mine at Valdez, Alaska, is shipping to the smelter at Anyox between 3000 and 4000 tons of ore monthly; the Mamie mine, on Prince of Wales island, between 4000 and 5000 tons. A number of others are producing on a smaller scale. This is moved through a subsidiary company owning and operating a fleet of steamers. The Grand Forks plant blew-in its seventh furnace on September 7. As the Crow's Nest Pass Coal Co. seems to have overcome its labor troubles and to be in a position to keep up a supply of coke, the eighth furnace should soon be in blast.

ONTARIO

COBALT. Silver production of the Kerr Lake mine in the first half of 1916 was 1,260,000 ounces.

To treat 500 tons of old and 1000 tons of new tailing daily, the Buffalo Mines Co.'s new flotation plant has been completed and started.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

H. H. WEBB is here.

JOHN M. NICOL is in Plumas county.

JOHN T. TOWERS is at Barkerville, B. C.

C. W. PURINGTON is expected at New York.

GEORGE WATKIN EVANS is in the interior of Alaska.

J. B. TYRRELL has returned to Toronto from British Columbia.

O. H. REINHOLT is touring in Arizona and will attend the Institute meeting.

M. M. VALERIS and V. H. MCNUTT are in New York on a two weeks' business trip.

W. S. GREYER is superintending operations at the Hudson Bay mine near Salmo, B. C.

W. YOLEN WILLIAMS of Spokane has been examining mines in the Ainsworth district, B. C.

CHARLES BUTTERS has gone to Chicago; from there he will proceed to New York and London.

E. H. WATSON has returned to the Lena district in Siberia, to take charge for the Olikma & Vitim Gold Company.

C. W. BOISE of New York has gone to the Belgian Congo, where his address is care Forminiere, Tshikapa, Kasai.

W. J. LAKELAND has resigned his position with the Burma Mines and has joined the Indian Army Reserve of Officers.

W. L. HOSKOLD has gone to New York to serve as chairman of the committee representing the Commission for Relief in Belgium.

WILLIAM TRICAN has returned to Georgetown, California, from London, having served for a year with the Ministry of Munitions.

GEORGE B. HOLDERER, recently manager for the Furlough Development Co. in Arizona, is now with the General Chemical Co., New York.

PAUL W. AVERY is visiting the principal copper mines of Arizona; he will attend the Institute meeting and then return to El Oro, Mexico.

GEORGE A. GUESS, professor of metallurgy in the University of Toronto, has been engaged to start the smelter of the Vermont Copper Co., at South Trafford, Vermont.

Obituary

BROOKE MOORE, chief chemist of the Mountain Copper Co., died suddenly at Martinez, California, on September 11. He was 38 years old, and had been with the company for 17 years.

FRANK McMILLAN STANTON died on September 12. The son of John Stanton, he had long been associated honorably with the Lake Superior copper industry, notably the Atlantic mine and the Copper Range group of companies.

When the American Chemical Society meets in New York on September 25 to 30, it is expected that with those attending the American Electrochemical Society's meeting and the Exposition of Chemical Industries there will be over 2000 chemists present. The Technical Association of the Pulp and Paper Industry will also hold sessions during the same week. The presidential address will be given by Charles H. Herty of the Society. There will be a symposium on colloids, industrial conferences, and many discussions. Chemical papers will cover agriculture and food, biology, fertilizer, organic, industrial, pharmaceutical, physical and inorganic, and water, sewage, and sanitation subjects.

THE METAL MARKET

METAL PRICES

San Francisco, September 12.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	28.75
Pig lead, cents per pound.....	6.75-8.00
Platinum: soft and hard metal, per ounce.....	\$85-\$89
Quicksilver: per flask of 75 lb.....	\$75
Spelter, cents per pound.....	12
Tin, cents per pound.....	41
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, September 12.

Antimony: 50% product, per unit (1% or 20 lb.)....	\$1.00
Chrome: 45% and over, f.o.b. cars California, per ton, 13.00-15.00	
Manganese: 50% product, f.o.b. cars California, ton.....	12.00
Magnesite: crude, per ton.....	7.00
Tungsten: 60% WO ₃ per unit.....	14.00

New York, September 6.

Antimony: The market is unchanged at \$1.10 to \$1.20 per unit, and very dull.

Tungsten: Over 450 tons has changed hands in the past few days at around \$20 per unit. For ore of special quality \$22.50 was paid for immediate delivery. Contracts have been made for October and November delivery, and the general aspect of the market is better.

EASTERN METAL MARKET

(By wire from New York.)

September 12.—Copper is firm and active, lead is quiet, but an advance is expected; spelter is firm on export enquiry.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending
Sept. 6.....	68.25
" 7.....	67.87
" 8.....	68.25
" 9.....	68.37
" 10 Sunday.....	68.00
" 11.....	67.87
" 12.....	68.10

Monthly averages

1914.	1915.	1916.	1914.	1915.	1916.
Jan.	57.58	48.85	56.76	July	54.30
Feb.	57.53	48.45	56.74	Aug.	54.35
Mar.	58.01	50.61	57.89	Sept.	53.45
Apr.	58.52	50.25	64.37	Oct.	53.12
May	58.21	49.87	74.27	Nov.	49.12
June	56.43	49.02	65.94	Dec.	49.27

The tone of the silver market is good, yielding a point or two on occasion, probably profit taking or lack of rivalry for supplies. Three weeks ago metal was sold on China account for India, thus checking the Indian demand in London and lessening competition with coinage orders. Movements of silver in England for the 7 months ended July 31 are as under:

1916.	1915.	1914.
Imports	52,399,133	53,995,002
Exports	20,150,667	19,167,991

The imports are remarkably even, but exports indicate the small quantity sent to India and the large amount retained in England for coinage.

Exports of silver from San Francisco during August totaled \$1,947,000. On September 9 metal worth \$750,000 was shipped to the Orient.

COPPER

Prices of electrolytic in New York, in cents per pound.

Tin is steady at 38.25 cents.

During the quarter ended June 30 the Vulcan Detinning Co. made a loss of \$8566. Sales totaled \$181,981. In six months the profit was \$11,982. The surplus is \$112,331.

Eastern Metal Market

New York, Sept. 6.

The entire metal market was adversely affected by the threatened railroad strike. During the uncertainty consumers had no inclination to buy. The quietness was continued by the Labor Day holiday.

Copper continues in a strong position, the scarcity of spot being so great that premiums are again near. The Allied governments are certain to buy millions of pounds for 1917 delivery, but so far price has been the obstacle to business in that direction.

The larger producers of zinc are well filled with orders, and the recent fluctuations of prices has been due to second-hand operations. Until the strike scare a good business was done. Prices are lower.

Many consumers of lead are short, and have been obliged to buy at advanced prices. With all producers well sold up, outsiders have obtained some fancy profits.

Consumers are showing little interest in tin. Their temper is not good for the reason that they are now taking deliveries of metal for which they paid more than prices now ruling.

Antimony is dull and easy.

Aluminum is strong at 60 to 62 cents.

The total of pig-iron production in August was 3,203,713 tons or 103,346 tons per day, against 3,224,513 tons in July or 104,017 tons per day. A slight increase in active furnaces was counteracted by heat and humidity. September is expected to show a gain. The buying of steel keeps up on a huge scale, many of the mills being well sold into next year. Foundry pig-iron has been more active; its prices, while firm, show no advance. August shipments of iron ore from Lake Superior established a new record, amounting to 9,850,000 tons. It is probable that the season's shipments will exceed 62,000,000 tons. August was a good month with metal-working machinery.

COPPER

Fear that the threatened railroad strike might come and the holiday this week made the market quiet in the past few days, but it is, nevertheless, strong at 28c. for spot or September metal, 27.75c. for October, 27.50c. for November and December, and 26.50c. for first quarter of next year. Spot is so scarce that it is highly probable that up to 28.50c. might have been paid for immediate shipment. The quotations given for near-by delivery are those of outside sellers, the producers being well sold up for the next few months. Up to the time of the scare over possible strike the market was fairly active. It is unquestioned that Great Britain and her Allies must have large quantities of copper for delivery next year, but they are unwilling to meet present prices. It is reported that they have offered 25 to 25.50c. It is understood that the British government will buy 250,000 tons. For such an enormous quantity it is natural, of course, that a price would be fixed considerably lower than domestic consumers of moderate-sized quantities would be asked to pay. For small lots out of store, jobbers are today getting 29 to 31c. The London market was quoted yesterday at £130, against £129 a week previous. August exports totaled 32,160 tons, a good showing. Statistics cabled to the New York Metal Exchange, September 5, show that stocks in Great Britain and France increased 1692 tons in the last half of August, the total supply in those countries on the 31st being 7514 tons. In the last two weeks of the month the quantity afloat for Europe decreased 1200 tons. The total visible supply on September 1 was 11,514 tons, 4000 tons of which was afloat from Australia and Chile. Lake copper is nominally quoted at about the same levels as electrolytic. The demands for brass and copper products show no diminution.

ZINC

The market was hard hit by the threatened railroad strike, and has not recovered. Despite a slight show of interest on the part of domestic consumers yesterday, the market is dull and prices are easy. Prompt can be easily obtained at 8.75c., New York, and 8.50c., St. Louis, and these figures probably could be shaded. October delivery can be had at 8.25c., St. Louis, November at 8.12c., and December at 8c. The larger producers assert that they are well filled with orders for the remainder of the year, and the recent ups and downs of the market are attributed to manipulation by second-hands. In August, domestic galvanizers took large quantities of the metal and that activity was followed by good export buying. On the 31st the Board of Managers of the New York Metal Exchange adopted a new ruling as to what constitutes a good delivery of zinc on contracts for prime Western. It follows:

"Prime Western shall be virgin spelter, resulting from the distillation of zinciferous material, and shall not contain on the average in excess of 2% lead and 0.08% iron. In case of dispute, one slab out of every ton shall constitute a proper sample. Re-melted spelter shall not be a good delivery."

The reason for the change is that for some time 90% of the prime Western spelter produced has run over 1½% lead, the maximum of lead under the rule which was displaced. When Joplin ores alone were used the product did not exceed 1½% lead, and the rule was easy of adherence. Lately it has been obsolete. Exports in August reached the excellent total of 11,352 tons. The London quotation yesterday for spot was £49, against £58 a week previous. Sheet zinc, carload lots, is unchanged at 15c., f.o.b. mill.

LEAD

Like all the metals, lead suffered from the recent disturbed railroad conditions. Fundamentally it is strong. Both the leading interest and independent producers are well sold ahead, but at the same time there are important consumers whose requirements are not covered. Yesterday, the 5th, the outside market jumped to 6.75c., New York, and 6.60c., St. Louis, following the appearance in the market of consumers who were forced to buy. Good sales were made at that price, and at 6.65c., Chicago, and more could have been done if the metal had been offered. The leading interest continues to quote 6.50c., New York, and 6.42½c., St. Louis, but when it sells it deals only with customers and then only in limited quantities, according to report. The situation has given outside sellers a chance to pick up some premiums for spot deliveries. August exports were only 830 tons. The spot quotation at London yesterday was £31, unchanged from a week previous.

TIN

The business of the week, and it was not a great deal, was in futures, of which 250 tons was taken August 31. The market is easier at 38.87½c. (September 5) for spot Straits. Banca continues to be offered for spot delivery, and has been sold at 1 to 1½c. under spot Straits. The trade was disappointed by the August statistics, in that they showed deliveries into consumption in that month to be 4335 tons, whereas it had been expected that they would be much larger. They were, however, above normal. Deliveries for eight months of this year total 40,388 tons, which is 8130 tons in excess of the same period in 1915. Of the arrivals in August, 535 tons came by way of Pacific ports. The U. S. Commerce Reports (August 2) state that the A. S. & K. Co. is obtaining good results at its tin smelting and refining plant at Perth Amboy, New Jersey. Early in August about 10 tons per day was produced, and it was hoped to increase the amount to 15 tons, the largest possible output with the present equipment.

Industrial Notes

Information supplied by the manufacturers.

A leaflet published by the E. I. DU PONT DE NEMOURS & Co. of San Francisco gives prices of explosives in the Western States.

The BRENNAN WAHL Co. of Chicago announces that it is prepared to act as consulting chemical, mechanical, and structural engineers, and as agents for machinery and allied products.

An Improved Centrifugal Pump

Development of the steam turbine and high efficiency multi-stage centrifugal pump has progressed together, but so far it has not been entirely practicable to reconcile the speeds of the two machines so that each would work at its best efficiency. Heretofore it was necessary to reduce the speed of the turbine and sacrifice much of its efficiency or else speed up the pump with similar results. To overcome this difficulty the Cameron Steam Pump Works of New York has designed and built a multi-stage centrifugal known as the "B-T" type.

The accompanying electro shows a completely assembled

CENTRIFUGAL PUMP AND STEAM TURBINE.

pump and engine. The speed feature is a virtue of the impeller design. With the ordinary impeller the diameter cannot be reduced sufficiently to get high speed without sacrificing vane length, and consequently efficiency for a certain vane length is necessary in order that the impeller may perform its function without excessive loss. Small external diameter and adequate vane length are obtained in this pump, by bringing the vanes well down into the impeller hub, at the same time so turning them that the incoming water is guided smoothly, and with little loss into the outer portion of the vanes where the velocity is generated that is finally converted into useful pressure by means of the external diffusion vane. Additional advantages in the small impeller are light weight and low fibre stresses in the material. Each impeller is cast solid in one piece and is of the enclosed type. The casing is divided along the horizontal centre line. Both the suction and discharge connections are in the lower half of the casing. The upper half is readily removable, giving full access to the revolving element. There are suitable openings for draining the pump and for displacing the air when starting. Inlet and outlet nozzles can be arranged either on the same or opposite sides, an important advantage where pumps are installed in limited space. The shaft is made of high-grade forged steel, and wherever it comes in contact with the fluid being pumped it is thoroughly protected by bronze sleeves. To take care of thrust, which manifests itself in all multi-stage pumps, this pump is equipped with a simple internal hydraulic balancing device.

EDITORIAL

T. A. RICKARD, Editor

MILLION-SHARE days are becoming frequent on the New York stock-exchange. Optimism is rampant. But we never think of Wall Street without regretting the number of dynamic men that devote great ability and unusual energy to the game of the ticker and the tape instead of being engaged in creative work.

GOLD imports, amounting to \$782,000,000 since the beginning of 1915, have not the economic significance of normal times, but it is certain that the accumulation will do much to fortify the Federal Reserve Bank and place the country on a sound basis, as against the period of disarrangement inevitable at the close of the War.

AMORTIZATION of the capital used in mining is a subject of direct practical interest, especially in these days when the amount of capital so used runs into huge sums of money. We publish an incisive article by Mr. Robert S. Lewis, Associate Professor of Mining in the University of Utah. We shall be glad to see the subject discussed in our columns.

TWO nominations have been made for the presidency of the American Institute of Mining Engineers: Mr. Sidney J. Jennings of New York and Mr. Philip N. Moore of St. Louis. Both are so well worthy of the honor that it seems a pity not to arrange for one of these gentlemen succeeding the other. Unless this is done the voting may be prompted by sectional sentiment, the Western men rallying to Mr. Moore while the Eastern cast their ballots for Mr. Jennings. Something should be done to prevent needless competition.

SENOR Luis Cabrera and his two associates on the International Commission are discussing Mexican affairs with Mr. Franklin K. Lane and the other two American commissioners, but the Mexican delegates are not wasting the time between these debates; they are making the most of a favorable opportunity to raise money, in the form of a loan. It is not clear to us how any banker is justified in lending money to the Mexican government under Mr. Wilson's doctrine that the United States is not called upon to protect the financial interests of its nationals abroad, particularly in Mexico. The money invested by Americans in the mines and other industries of Mexico went there on a guarantee of protection and fair treatment from the Mexican government, and on the understanding that the American government would insist on such protection and just treatment. But the administration at Washington has washed its hands of the bold bad men that go to Mexico

to engage in legitimate speculation and honorable industry, so how can any banker feel safe in loaning money?

FLOTATION royalties were discussed in our last issue. In the July statement of development, production, and costs at the Goldfield Consolidated we note the following: flotation royalty, 5 cents per ton of total ore, and filter royalty 3 cents. Previously this company was paying 5 cents per ton as filter royalty. The introduction of flotation evidently has reduced the quantity of pulp filtered. As mentioned on page 438 of the September 16 issue, flotation at the Goldfield Consolidated has been suspended for two or three months pending installation of additional apparatus, cyanidation being resumed meanwhile. Treatment charges, excluding royalty, amount to \$2.11 per ton.

ON another page we give an abstract of a useful paper prepared by Mr. Hennen Jennings, assisted by Mr. Charles Janin, on dredging in Montana. The information deals principally with the Conrey Placer Mining Company, which operates four large dredges at Ruby. In our issue of December 25, 1915, Mr. Jennings gave us a few notes on results obtained, but this is the first time that such detailed data have been made public. Alder Gulch and Ruby were the birthplace of many important improvements in dredges, such as are typified in the big machine now at work there. Mr. Jennings concludes his paper as follows: "Outside the practical economic considerations involved, it appears that the development and working of a great gold-dredge has a very far-reaching and ethical meaning. The No. 4 Conrey dredge may be taken as an example. This was the product of no one locality, the child of no one brain, but rather the result of persistent and progressive effort in all dredging-fields and machine-shops, extending over nearly 20 years, and behind these efforts were the scientific and inventive discoveries of the age. Its record month's work of 400,000 yards, or 600,000 tons, to a depth of 54 feet, must be considered in connection with the statement that the total number of men at work on this dredge was only 10 in all. Yet, with the mighty steel and electrical tools at their command and the force chained to service from water-falls 26 miles distant, these men on the firing-line and supported by the machine-shop reserves could each be accredited with having raised 2000 tons of gravel, some of it from a depth of 54 feet below water to 40 feet above; then sorting the gold-bearing gravel from the barren, spreading it out on gold-saving tables, extracting the gold, and then elevating and

stacking the waste in such a way that future operations were in no way impeded, and all for an operating cost of about three cents per ton, and this in eight hours. How many men with mere muscular energy at their command and primitive appliances would it have taken to do this work? To the writer it would appear that the miner, mechanic, metallurgist, chemist, engineer, and scientist have increased the laborer's power in this instance a thousand-fold and created for him work necessarily abandoned under old conditions." These are just observations, and they are stated by no mere novice, but by a man of world-wide experience. Yes, the art of mining, also that of metallurgy, depends upon the co-operative effort of the many workers rather than the single effort of the individual genius. It is the aim of a professional paper such as this to co-ordinate the work of the many and bring them in mental touch.

A Walled Mexico

Carranza is trying to build a wall of exclusion around Mexico. With every new decree the hopelessness of re-establishing normal relations with the devastated republic grows deeper. Capital and an army of peaceful workers have been eagerly waiting to resume the task of reconstruction, but the protection of our own Government is withheld, while new barriers are daily erected by Mexico. Carranza has found encouragement in his follies from the incomprehensible attitude of President Wilson. When the chief magistrate of the United States utters platitudes befitting a high-school debater, affirming that he believes in the right of the Mexicans to do as they please with their own country, and that Mexico is justified in concluding, from the way in which some of our fellow-citizens have tried to exploit her privileges, that we wish to possess her, and adds that he will not serve the ambitions of these gentlemen, but will "try to serve all America by trying to serve Mexico herself," Carranza has warrant for thinking that the rights of our people may be ignored with impunity.

It was a quibble to assert that a country may do as it likes. Japan was able to live according to its own lights while its ports continued closed against the world, but President Wilson might have reflected that no other than the United States of America took the initiative in denying Japan's right to voluntary exclusion as a hermit kingdom. When Commodore Perry in 1853 forced open Japan's doors, the United States gave peculiar emphasis to the necessity for commercial intercourse as a fundamental principle henceforth to be recognized within the family of nations. Intercourse is regulated by formal conventions, and as soon as a nation enters into a treaty of amity and commerce it has limited its self-centred independence by a new set of mutual rights and obligations.

It is the duty of our Chief Executive to sustain the rights thus acquired in Mexico. No decree of a *de facto* government can impair them legally. Our treaties give us the most-favored nation privileges, which place our

nationals, in nearly all respects except political status, on an even footing with the citizens of Mexico, subject to the municipal law of the land. Only a constitutional government can alter these, and Mexico is today without such a government. In recognizing Carranza, the President merely became a party to the carrying out of treaty engagements subject to previous constitutional enactments, as *ad interim* administrator of the affairs of Mexico. Nevertheless, the innocent investor is abandoned because a few have wrongfully used their influence and financial strength, so the future investor, though reading in the solemn treaties ratified by his country's Senate what rights he possesses in Mexico, finds that the penalty for daring to go abroad and invest his labor and his money is expatriation.

In time, if Mexico finally should settle down to orderly government, it is to be presumed that rational treatment of foreigners will be accorded by statutes in conformity with her treaties; but the outlook for internal peace becomes daily less promising. The future is still more darkly over-shadowed by one of Carranza's latest decrees. Behind the revolutionary bombast of ambitious leaders, and underneath the ravaging fury of loot-maddened mobs, lies a reasonable and comprehensible revolutionary purpose. This is the profound intent of the defrauded poor to regain their lands. The pitiful story of systematic robbery by legalized injustice, whereby the lower classes were stripped of their inheritance and made little better than serfs on the land that had once been theirs, may be read elsewhere. The indictment against the land-grabbers, and the demand for restitution, can be found clearly and succinctly stated in just one Mexican document, and that is the *Plan de Ayala* formulated by the bandit Zapata. Every other leader of prominence has declared for the same reform, and by doing so has been able to gather supporters to his standard, but these are like the factitious planks in the platforms of our political parties compared with the ingenuous presentment and demand appearing in the proclamation of Zapata. Here is found the spirit of the Mexican revolution, the revelation of public wrong and the vision of justice that the spurious reformers have proclaimed only in feeble and halting phrase. It matters little what we may think of a demand for nearly universal confiscation of real property and its redistribution among the poor. The practical difficulties in the way of such a proceeding, the inevitable hardship and unfairness that would be wrought in the name of justice, the impossibility of carrying out equitably so radical a reform, these are matters for the Mexicans, not for us. The thing that we should recognize, however, is that agrarian reform is the popular motive of the Mexican revolutions, and that revolutions will not cease until the grinding injustice of the brutal old landlordism has been atoned in some quite effectual manner and rendered impossible of recurrence. Such semblance of peace and of constitutional government in Mexico as may come while this question remains unsettled will be evanescent. Stability of government is not to be antici-

pated until a genuine agrarian reform has been placed on a workable basis.

Carranza is, of course, the owner of great estates. He acquired them in the conventional manner of the old land-thieves. The people have never ceased to whisper that he espoused the cause of the revolution in order to avoid confiscation of this property. Now comes announcement of a plan that strongly confirms the suspicion. The moral ground is artfully shifted. The guilt for which confiscation shall apply is crime against the government of Mexico. The manner in which land-titles were obtained does not enter into the question. Degrees of culpability are recognized, with graded punishment. Those who took up the great cause of liberation and reform have naturally washed out considerable original sin. Carranza is proposing to do by this decree precisely what Zapata long ago prophesied that he would.

To count on Mexico as a field for enterprise until the real problem of the masses is faced and dealt with practically by some capable leader is to ignore the verities of the situation. Carranza is a crafty demagogue of the old *científico* class. Zapata an illiterate peón possessed of an idea too big for his mastery, Villa too easy a prey to vanity when flushed with successes to measure up to the dignity of great responsibility. The day of regeneration for Mexico has not yet dawned, despite the clamor of some false prophets; neither is the day near when Americans may return to develop the mineral and agricultural resources of Mexico with assurance that their rights will be sustained in keeping with the truth plighted between Uncle Sam and Guadalupe in their now long-forgotten treaties.

Elmore and Flotation

On another page we publish an intensely human document, nothing less than a personal statement by Mr. A. Stanley Elmore, in behalf of himself and his brother, Francis Edward Elmore, covering their invention of the original bulk-oil flotation process and the later developments of this metallurgical method, with special reference to the unpleasantness between them and the gentlemen now identified with the Minerals Separation company. We had written to Mr. Elmore asking him for sundry items in the chronology of the early flotation work, but instead of a dry record he sent an appeal addressed, through our columns, to the profession at large, more particularly those, and they are many, interested in the quarrel between the two groups of men so long engaged in a contest over the rights to the basic patents and the profit that flows from them.

Those that have read the recent book, 'The Flotation Process,' will be able to follow Mr. Elmore's statement intelligently, even sympathetically, for the editor and compiler of that volume is numbered among the many that think the Elmore brothers were given the short end of the stick in the pull between the opposing interests. Much of what Mr. Elmore says is already known in

London, where the flotation vendetta is better understood than the technology of the process, but it will convey a good deal of fresh information to our readers on this side of the Atlantic. We have refrained from editing the statement, preferring to give it exactly as it came to us; otherwise we might have deleted the Herodotus story, which is apocryphal. The emphasis on the dryness of the ore treated by Haynes and Everson is to the point. As our readers are aware, we take no stock in the Everson myth, which was over-worked by the opponents of Minerals Separation, no less than by those of the Elmore brothers. The argument that George Robson avoided "the use of an excess of water" is new, but it is not unreasonable, because he depended upon the direct agency of an excess of oil, as much as three tons of oil to one of ore. Mr. Stanley Elmore recites the way in which his brother first became interested in the subject, but he does not explain that the plant in which his first experiments were made was the one, at the Glasdir mine, in which Robson had made his ineffective attempt. We ask him to clear this part of the history; for we have been informed on good authority that Mr. Frank Elmore found the remains of Robson's experimentation, in the form of oil, pulp, and apparatus, at the Glasdir mine when he himself first arrived there. In the statement by his brother we are told that an observation of the effect of lubricating oil, dropping on a launder, in concentrating particles of chalcopyrite, suggested the use of oil as a flotation agent. Possibly this, and the other observations mentioned, led to experiments with Robson's apparatus. If there was no connection between Robson's abortive effort and Elmore's valuable invention, it should be made known. Mr. Stanley Elmore does not give the name of the mine. The fact of such a connection between Elmore and Robson would be interesting and it would not detract from Elmore's credit as an inventor, for Robson failed in devising a workable method, while Elmore succeeded, thanks mainly to his unquestioned skill as an engineer.

Next we come to the beginnings of the Elmore syndicate. It is obvious that the start was auspicious, in that it was made with the financial backing of Wernher, Beit & Co. and with the benefit of the engineering experience of such men as Messrs. Walter McDermott and Hennen Jennings. Mr. Frank Elmore had recognized the use of a thin pulp, that is, the presence of plenty of water, so that the oil might have "a free choice between the wet mineral particles and the wet rocky particles"; but, in his first invention he missed the third essential, one as important as the water and possibly more important than the oil—namely, air. Reference is made to Mr. C. M. Rolker's paper on the Elmore bulk-oil process as conducted at the Glasdir mine, a paper read before the Institution of Mining and Metallurgy in London on April 25, 1900. To those familiar with the recent development of the flotation process it is intensely interesting to note that at that meeting several references were made to the fact that while the difference of specific gravity between the oil and the water gave a floatative margin of 10%, yet

the oil was loaded to as much as 28%, and even then "the oil had an ample amount of buoyancy to allow of it readily floating on the surface of the water." I quote Mr. McDermott. On that occasion Mr. Frank Elmore quoted the manager, the late John Bevan, as saying that the flotative efficiency of the oil was 25% against the theoretical load of 10%, and he, Mr. Elmore, remarked that "it seemed rather strange that there should be such a difference between theory and practice." Of course, we see now that all of them failed, at that time, to detect the part played by the air, which was entrained with the ore and water while they were being mixed in a revolving drum. Mr. Rolker said: "The viscosity of the oil is the all-important point." Mr. McDermott said that "there was no doubt that the success or failure of the process depended largely on the amount of oil lost in the operation." Nobody, neither Mr. H. L. Sulman nor Mr. H. F. K. Picard, who also took part in the discussion, made the slightest reference to the agency of the air in promoting the flotation of the chalcopyrite. As far as we know, the first public recognition of this basic fact was a statement by Mr. McDermott, in the *Engineering & Mining Journal* of February 14, 1903, when the present writer was editor of that journal, acknowledging that "the agitation with the pulp results in the oil taking up a very appreciable quantity of air." It remains to add that on January 3, 1903, Mr. Stanley Elmore took out a patent to *exclude* air from the apparatus, by means of a ring or surface of oil, the idea being to prevent the oxidation of the minerals, but the result was to banish a prime agent in the separation between the sulphide particles and the gangue. We hasten to say that the Elmore brothers were the first to take practical cognizance of this error, for their vacuum-oil patents of 1904 are based on the use of air naturally dissolved in water, and from these patents the growing recognition of the part played by air was emphasized progressively until today the process is essentially one performed by a maximum of bubbles generated in the presence of a minimum of oil as against the original Elmore operation in which a maximum of oil was aided surreptitiously by a minimum of air. Returning to Mr. Stanley Elmore's statement, we agree with him that the establishment of a demonstration plant in London, in 1901, and the access thereto granted to metallurgists, together with the lavish publication of information concerning the process, did do a great deal to stimulate interest and curiosity, contributing thus to the later developments whereby the process was turned inside-out and made of inestimable value to the mining industry. For instance, these publications served to attract the attention of Aleide Froment, in Italy, and caused him to make experiments destined to play a decisive part in the development of flotation. What Mr. Elmore says about the experiments in agitation, including the use of the Gabbett mixer and centrifugal pump, as early as 1902, is interesting, for this led, we presume, to the recognition of the assistance given by air and thus to the vacuum patent of 1904. It is claimed that from that date "minute pro-

portions of oil with violent agitation were in constant use, producing a 'froth' in industrial plants on a large scale." We do not doubt that 'froth' was formed under such conditions. What is a "minute proportion" of oil? Of course, to anybody that has used a ton or more of oil per ton of ore, anything like 10 pounds per ton seems minute; and in later plants the oil employed with the vacuum process has been reduced to less than 3 pounds per ton of ore.

This brings us to the episode that did so much to embitter the relations between the flotation groups in London. Mr. Elmore tells the story of the option granted to Messrs. Hay, Webster, and Ballot in 1901 and the access given thereby to the Elmore plant and operations, whereby Messrs. Sulman and Picard were enabled, in 1902, to become familiar with every detail of the process as then conducted. To what extent, if any, Messrs. Sulman, Picard, and Ballot took advantage of this opportunity to learn the Elmore methods and how much they were aided thereby in devising the method patented by them in 1905, it is not for us to say, seeing that the matter was ventilated in a court of law, but it is obvious that Mr. Elmore expresses a keen sense of betrayal. We know that both of the Elmore brothers resigned from the Institution of Mining & Metallurgy when Mr. Sulman was nominated to the presidency of that professional society in 1911, but this incident indicates the bitterness rather than the merits of the quarrel; it is a fact, however, that the option episode has been at the bottom of the acerbity shown in the litigation ever since. The decision of the German patent-office, in 1909, is recorded in the books on flotation, but some of our readers may have overlooked it. But the more important note is that concerning the first litigation over the Froment patent, purchased in 1902 by Minerals Separation, the company organized in 1903 by Messrs. Hay, Webster, Ballot, Sulman, and Picard to buy the Cattermole coagulation patents. In 1914 the Elmore people, on final appeal, lost their suit for infringement against Minerals Separation, but this suit referred solely to the old bulk-oil process and ignored the improved vacuum or air method. Therefore the decision was of no moment to the American users of the process. The main contest over the patents is now in progress in the United States, as our readers are aware, by means of the suits brought by Minerals Separation against James M. Hyde and the Miami Copper Company, respectively. Here we leave Mr. Elmore's appeal. It will be read with keen interest, and we hope it may be followed by the information for which we have asked on one or two obscure points. Meanwhile, the profession at large will, we believe, join with us in recognizing the great service done to the industry by the Elmore brothers in their early development of the flotation process and in their later invention of the vacuum method whereby the agency of air became recognized, increasing the efficiency of a process that has revolutionized low-grade base-metal mining and bids fair to play an increasingly useful part in the concentration of the precious metals.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

MacDougall

The Editor:

Sir—Referring to your note in the issue of September 9, in regard to the proper spelling of the name 'MacDougall': The earliest reference that I find in our library is in the second edition (1891) of Vol. 1 of Lunge's 'Sulphuric Acid and Alkali,' where it is spelled MacDougall. Reference is therein made to British patent No. 3985, dated 1883, in which the inventor's name would, of course, be found as he himself spelled it.

CHARLES D. DEMOND.

Machinery in Mining

The Editor:

Sir—The changed conditions affecting the cost of mining in California as compared with practice in 1869, given in your article on 'Re-opening of Old Mines Along the Mother Lode,' in the issue of August 12, should be of interest to those living in other mining regions. I was surprised to know that nitro-glycerine explosive was used in Californian gold mining as early as 1869. Its first use in America was, I believe, in 1867* at the Hoosac tunnel in the Berkshire hills of Massachusetts. Hand-drilling and blasting with gun-powder had been responsible for the comparatively slow work done in tunneling and mining. I had an idea that the low cost of mining today compared with the cost in 1869 was due principally to two influences: first to the introduction of improved machinery and high explosives, and secondly to the consequent speeding-up of the workmen as the unconscious result of handling fast-operating machinery in an age and country famous for their 'hustle.'

The point of view of the workmen is important. H. Foster Bain, in commenting on underground conditions in the gold mines of the Rand, speaks of the stopping of all rock-drills in a stope when a visitor enters, a customary matter of courtesy.† He adds "there is not the drive to the work to which an American is accustomed." In very few large American mines today are the rock-drills stopped when a visitor enters a stope. The spirit of the times here is opposed to such waste. I presume that in 1869 looser ways prevailed. I know that old Lake Superior miners relate how, 20 or 30 years ago, they customarily smoked and talked an hour underground before proceeding to work. In one large Michigan mine for

years the miners slept on night-shift after the midnight 'lunch.' Today the "drive of the work" in American mines to which Mr. Bain refers, is a decided change over the easy-going methods of the '60 and '70s. This should accrue to the advantage of a company re-opening a mine such as the Old Eureka.

Scarcely anyone will deny the tremendous speeding of underground work by the modern fast rock-drill, the steam or electric pump, and the improved high explosives. J. N. Wright, a former superintendent at the Calumet & Hecla mines, writing in 1895, said: "I have alluded to the great cheapening of the cost of production that has enabled the Michigan copper companies to maintain a profit in spite of reduction in the price of metal. The two agencies that operated to bring about this result were power-drills and high explosives. The great expense of a Michigan copper mine is the actual breaking of the rock, this being about double all other costs. For years engineers had endeavored to perfect a machine-drill. About 1870, the Burleigh rock-drill was tried at several of the copper mines, but, owing to its great weight and size, could be used in but few places, and the saving effected over hand-drilling was small. A few years later, drills of much lighter weight and of stronger construction were perfected and were soon introduced into all the mines. In 1879, the Calumet & Hecla company, after a careful trial of the new drills, decided to introduce them throughout the mine as rapidly as they could be obtained, and an air-compressing plant was erected to supply motive power. High explosives (the nitro-glycerine powders) were also introduced at the same time. Previous to this all drilling had been done by hand, and only black powder used in blasting." From the above it is evident that the Michigan copper mines, largely owned in Massachusetts where the experiments with rock-drills and nitro-glycerine were initiated, tried the Burleigh rock-drill in 1870 and found it unsuccessful. Nitro-glycerine explosive seems to have been adopted at the Michigan mines in 1879. Mr. Wright continues: "The result was that in sinking, drifting, and stoping, the price per foot and per fathom, respectively, was reduced one-half, and a saving of at least \$200,000 effected. A few years later this saving over hand-labor amounted to \$500,000 per annum, and at present (1895) with largely increased production, I am confident that \$2,000,000 would not misrepresent the annual saving by underground machinery at the Calumet & Hecla mine alone. This is the direct saving, but it only partly expresses the net result, for the indirect advantage is great. Not only were prices reduced one-

*M. & S. P., Oct. 10, 1914.

†M. & S. P., Aug. 26, 1916.

half, but as the same force of men were enabled to do double duty, the company was soon able to double the amount of output upon which its profit was based. Trouble from smoke and foul air was also greatly diminished. We have heard much in recent years of wages reduced and men thrown out of employment by the introduction of labor-saving machinery. But such has not been the case in the Copper Country. To operate the machinery, which had replaced the old hammer-and-hand drill, greater skill was needed. Brighter men found employment, and the wits of the older and duller men were sharpened. Their ambition was stimulated, and they were able to do, and did do, better work than before. Their wages were increased instead of diminished, and the company, profiting by the increased output, not only retained all their men, but gradually added to their number."

It would seem that Mr. Wright, writing 20 years ago, described an industrial revolution much the same as took place in the Copper Country during the last five years when the one-man drill and 'efficiency' ideas were introduced. James MacNaughton stated recently that "the use of the one-man drill and Carr bit at the Calumet & Hecla mines has resulted in an increased output per miner equivalent to his total production of a few years ago."

That labor-saving machines economize work is unquestioned, but that a further advantage ensues from providing more work is not so well understood. Putting a mechanical drill-sharpener in a mine's blacksmith-shop immediately effects reduction in the cost of sharpening the drills. But, as pointed out by the *Compressed Air Magazine*, the consequent ease and quickness with which drills can be sharpened leads to more frequent sharpening of them; that is, when a bit becomes worn, the miner does not waste time trying to work with a dull tool, but changes to a sharp bit; he knows that dull bits can be sharpened easily and cheaply. This procedure is typical. The speeding of one link in a chain of connected operations is likely to spur others, and one improvement leads to another. The principle that the saving of work makes more work sounds paradoxical, but is quite as true as the axiom that "money makes money, and the money that money makes makes more money."

Referring again to your article 'Re-opening of Old Mines Along the Mother Lode,' surprise might be expressed that miners' wages in California today are nearly the same as in 1869. We are accustomed to think that the wages of all workmen in the United States have risen steadily since a generation ago, partly on account of the increased cost of living. This is exactly the reason why wages on the Mother Lode have not increased, because the cost of living there is lower than in 1869. In those early days the high freight-rates and the lack of agriculture in California made for high prices in most of the necessities of life. Today a miner in California can, and does, support a family in comparative plenty on the wages that in 1869 only sufficed to keep a single man in good health and spirits according to the generous stand-

ards of those bluff times. The cost of living in California has increased recently by reason of the widening demand for luxuries, but a miner on the Mother Lode lives most comfortably in the snug mining towns, reinforcing his wage by the produce from his garden and by the modern facilities for economizing in the home.

Berkeley, August 15.

P. B. McDONALD.

Lime From Molluscs

The interruption of the usual supply of lime, at a Mexican mill recently, made it necessary to find a local supply until importations could be resumed. Fortunately the mine was not far from the sea-beach, where there were large mounds of oyster and clam shells. The natives for a long time had produced lime by burning the shells in heaps. Small-scale tests indicated that lime could be produced economically in this way. It was found that the clam-shell was higher in lime content and more easily burnt than that of the oyster.

A small vertical brick furnace was first tried but discarded. The flames would not pass through a column of shells more than a foot or two in height. When heated the shells began to disintegrate, closing the air-passages and damping the fire. As fire-wood was cheap and plentiful, burning in heaps was tried. A few logs or pieces of old timber were first laid down, about a foot apart, covering a space 10 by 20 ft. On these was spread a layer of fire-wood making a floor for the shells, which were piled to the thickness of six or eight inches. Another layer of fire-wood was followed by a layer of shells until the heap was about four feet high. A few logs were placed upright in order to leave vents in the mass after they had burned. About three cords of fire-wood was needed to burn ten tons of shell. The wood was ignited from the centre of the heap, where oiled waste had previously been placed. In 24 hours the wood was consumed, leaving a hot glowing mass, which was allowed a day to cool.

The fire-wood was dry and burned to a white ash, leaving little charcoal, which would have been objectionable in the cyanide solutions. Lime yielding 39% CaO was obtained using this method. Two pounds of the shell-lime was approximately equal in strength to one pound of good rock lime. There was a loss in weight in burning of about 25%, so that 10 tons of shells produced about 7½ tons of lime. Some of this lime was used for mortar and found satisfactory.

The zinc-lead deposits of Brecken Hill, Rhodesia, are the only important ones known in South Africa. The metals occur as carbonates, and owing to their intimate mixture, coupled with the long distance from market, the deposits so far are unprofitable.

IRON-ORE SHIPMENTS from the Lake Superior districts up to September 1 totaled 39,215,864 tons. This is over 7,000,000 tons in excess of the same period of 1913, a record year.

The Invention, Development, and Introduction of the Flotation Process

By A. Stanley Elmore

For some considerable time past I have been urged by friends to prepare for publication some notes on the history of the flotation process; several reasons have conspired causing me to hesitate. First I very much dislike anything which might look like "blowing my own trumpet;" second, I believed that the facts were pretty generally known to that considerable circle of personal friends I am glad to have among engineers and metallurgists who have studied this matter and who know to whom the credit for the first invention of the flotation process is due.

Notwithstanding the sympathetic dedication to my brother and myself of Mr. T. A. Rickard's interesting book 'The Flotation Process,' I feel the necessity of such an authoritative statement as I am asked to make, if the real history of this matter is not to become buried under a mass of prejudiced statements and legal subtleties advanced by various people whose only desire is the present support of a particular position in an involved law-suit.

Moreover, there appears to be so much misconception among others in connection with a few simple matters that I will endeavor as briefly as possible to set down the actual facts.

It would seem that the varied assortment of travelers which have passed along the highway of flotation do not appear to have been animated by the same intentions and desires. Some have trodden the road carefully, noting and correctly interpreting the inscriptions on the sign-posts. Others have read and failed to understand these inscriptions, while others again have accepted money-payment for attempts to obliterate and alter the original wording, in the hope of confounding the non-technical legal gentlemen who were expected to traverse the road after them.

The first sign-post on the road was erected by Herodotus about the year 450 B.C. Although the inscription is so old it is quite distinct and tells of a band of virgins, who, by daubing feathers with pitch and subsequently drawing them through the mud of a certain lake on an island called Cyranis where they were in the habit of bathing, recovered gold-dust in this way.

There is no record of these chaste maidens having been greatly enriched by the working of this simple metallurgical process, but notwithstanding this lack of evidence of 'utility' a certain learned counsel had the temerity to suggest that this "prior publication" invalidated the Elmore patents, which were filed several thousands of years later!

After a tramp of some two thousand years or more

we arrive at the sign-post erected by Haynes in the year 1860. This gentleman wrote a clear unambiguous inscription telling the reader to grind *dry ore* with an "agent" consisting of guttapercha, resin, India rubber, tar, oleaginous matter, in a 'pug' (or mortar) mill; the other things he told one to do need not be quoted because they are not so clear, and it is sufficient for the development of my argument that the beginning of the process he suggests was to grind *dry ore* with a mixture of guttapercha, etc., etc.

It would be an insult to the intelligence of a present-day metallurgist of independent judgment to discuss this sign-post as an anticipation of the flotation process, so we may pass on to the Carrie Everson inscription, dated 1885, which again instructs the reader to incorporate his dry ore with mixtures of oils, etc., etc., till such time as the mass becomes of a putty-like consistence.

Not a practical detail of how to carry out the operation is given; it is in substance the same as Haynes, and they are both of about the same practical utility as the efforts of the virgins to obtain the grains of gold from the mud of the lake—who knows, perhaps this gold defiled by contact with pitch was the "filthy lucre" of the scriptures!

It is a comparatively short step from Carrie Everson to Robson & Crowder, who put up their sign-post in 1894. They described a process for mixing with ground ore containing from 25 to 30% of moisture certain mixtures of fats, etc., and subsequently from the mass so formed elutriating the fine particles of mineral by means of a stream of kerosene-oil forced through it by a pump. Their directions for carrying out the process include specific instructions to avoid the use of an excess of water.

I have summarized these various suggestions—they were nothing more—in a few words because the original documents are all available and the great majority of engineers have doubtless read them. I have emphasized what to my mind is the cardinal point in connection with them, namely, they all were designed to operate by mixing the oil with dry or practically dry ore.

The successive suggestions so far mentioned added nothing whatever to the stock of public knowledge.

It has been said that the modern flotation process is the result of a gradual building up of experience and information, but I cannot accept that statement as applying to the period I am now dealing with. It is perfectly clear to me that neither Robson, Everson, or Haynes had the least idea of the cause of their own failure or of that of their predecessors.

Not one of these people ever described a process workable on a practical scale, neither did any one of them describe a practical form of apparatus for performing the proposed operation.

Notwithstanding the ransacking of ancient records, the raking over of the dust-heap of past failures, not one particle of reliable evidence has ever been produced that any of these suggestions did or could arrive at the stage of practical operation on a commercial scale. Nor has even the boldest of the attackers had the courage to try and demonstrate the working of any of these ideas in a large plant—for the very sufficient reason that they know it is impossible. Not one of these hopelessly impracticable schemes has ever emerged from the oblivion into which they fell and which they are so well calculated to adorn.

Failure is inherent in them, as every engineer knows, and it remained for Frank Elmore to discover the solution of the difficulty.

My appeal for an unbiased reading of the description of the suggestions set out above is addressed to engineers and metallurgists whose judgment will not be warped by their commercial interests and associations. I do not hope to obtain a fair hearing from those dishonest 'experts' whose veracity and conscience are elastic in proportion to the importance of the fee they get. Neither do I expect any admissions of value to this discussion from witnesses who will swear to particular facts in one Court and with equal solemnity swear to the exact opposite in another Court, justifying themselves on the ground of "change of opinion in the interval."

This little digression brings us along the highway to the sign set up by Frank Elmore in 1898.

Perhaps a few words which I think have not previously been published may be set down here as of interest as showing why and how Frank Elmore came to invent the flotation process.

At the time I speak of he was an engineer of known reputation having had a first-class scientific training in mechanical, electrical, and metallurgical engineering and wide experience of works construction and management, and was then in control of large metallurgical works in this country producing copper tubes and sheets by means of the Elmore electro-depositing process. He was recognized as possessing that rare combination of an imaginative or inventive mind coupled with sound practical ability to design plant for applying on a commercial scale the product of his imagination.

At this time William Elmore (his father) made a considerable investment with friends in a low-grade auriferous copper mine in this country. In due time an important plant consisting of the usual jigs, shaking-tables, etc., was erected and proved after the expenditure of much time and money to yield so low an extraction as to result in financial loss.

My brother and I were asked to investigate and see if the extraction could be improved. On the occasion of one of our visits to this mill it was observed that at the angle where one of the launders carrying the waterborne pulp deflected the stream, some splashing took

place, and it so happened also that oil had dripped onto the outside of the launder at this point from a shaft-bearing immediately overhead; a strong sun was shining upon it and a glittering reflection attracted the eye. On examination it was noted with interest that adhering to the oil was a coating of what appeared to be quite clean copper-pyrite and it was remarked that no rock seemed to adhere to the oily surface. A little later a piece of ordinary 2-inch iron steam-pipe, which was in such a position that the discharge from one of the slime-launderers splashed against it, was found by us to have a clear picture of a man's hand printed on it in bright copper-pyrite. It had been carried in a greasy hand and the whole of that part of the surface which had received a very thin coating of grease by contact with the hand subsequently became coated with pyrite.

It was these two accidental observations which led to the invention of the flotation process. These were the source of Frank Elmore's inspiration—at that time he had no knowledge of the virgins of Herodotus, nor of Haynes, Everson, or Robson & Crowder.

The fact was before us that finely-divided wet copper-pyrite would adhere to a greasy surface, whereas finely-divided wet rock would not. A means of separation was here indicated, experiments were immediately undertaken—on a small scale at first—gradually increasing in importance as encouragement was obtained.

The result of this work was the filing of Frank Elmore's patent of 1898. The process there described was applied on a practical scale at the mine referred to—one full-size working unit was first installed and others later.

Trials were being carried out on other ores and it gradually became known that we were working on a new method of concentration.

Up to this stage of development (a practical working equipment operated day and night by ordinary mill-labor) the whole of the funds—a large sum—had been provided out of our own pockets, as we were not desirous of inviting outside financial aid on something so startlingly new until we were convinced by practical results that we were justified in doing so. However, we were asked by my old friends Walter McDermott and Hennen Jennings, who had heard a little of what we had in hand, to let them see the process in operation. As a result of their personal inspection of the working-plant we were invited to allow them to make a thorough investigation by C. M. Rolker both of the mine and the process, and subject to his favorable report to join us in future development. In the end the mine was turned down at the price asked but McDermott, Jennings, and Werner Beit & Co. became financially interested in the process.

This then is a short account of the legitimate birth of what has turned out to be an epoch-making invention which has conferred a benefit of millions of pounds on the mining and metallurgical industries all over the world.

The inventors having thus associated themselves with men of high repute both from the technical, financial, and commercial side, naturally enough congratulated

themselves and were modest enough to believe that stability would be added to the business, progress be more rapid, and any tendency to 'swelled head' or demands for excessive royalties by enthusiastic inventors be kept better in check than it would if they had gone on entirely by themselves.

Now let us see how this invention so well conceived, so excellently supported, and with such bright prospects, remunerated the inventors and capitalists for the investment of their energies, enterprise, and money.

First let us understand what Frank Elmore had in fact invented, let us see in what main outstanding way what he did differed from those who are now said by a certain class of 'experts' to have anticipated him.

He accomplished by what, it is no exaggeration to say, was a stroke of genius:

(a) A continuous-working process.

(b) The treatment of the ordinary product of the almost universally employed wet-crushing plants.

(c) A practical form of apparatus mechanically perfect and capable of successful operation by ordinary unskilled labor.

Not one of these things had been accomplished by any of his predecessors who had made suggestions for the treatment of ores with oil.

It is easy to see why Frank Elmore was able to achieve so much in so short a space of time—to materialize all that is conveyed in the three simple statements (a), (b), and (c) above—to command commercial success where only failure, complete and unequivocal, had preceded his work.

It is quite obvious to those who bring an unprejudiced mind to the investigation that Frank Elmore was the first to appreciate the real fundamentals required as a basis upon which to build.

It fell to his lot to make the great discovery—simple in itself—that the essential element of success was the introduction of the oil to the ore in the presence of a large quantity of water; in other words, to give to the oil a free choice as between the wet mineral particles and the wet rocky particles. This fact, of cardinal importance, had never been recognized, appreciated, or understood before—had never been hinted at in any of the earlier adumbrations. In sober fact Frank Elmore did exactly the reverse of what had been attempted before—he did what he was warned not to do; he succeeded where those issuing the warning failed. Yet there are still to be found those who will for fees paid say that what he did was the same as what had been attempted by the earlier workers who had specifically rejected the very thing which gave Frank Elmore complete success.

The following few lines from one of the claims in Frank Elmore's first patent is ample justification for what I have said on this point:

He describes his process as "mixing the pulverized ore first with water in considerable quantity, then adding to the mixture an oil of the kind described, which adheres to the metallic constituents but not to the wet rocky constituents."

stance of the science, art, and practice of the flotation process as known today.

Here for the first time one is told in plain words the three essential elements for success (1) pulverized ore (2) a large quantity of water (3) the addition of oil of a kind which will adhere to the wet metallic particles but not to the wet rocky particles.

Everyone knows that prior to Frank Elmore's patent the oil was to be mixed or ground together with the dry or substantially dry ore. The oil was thus effectually forced into contact with both the metallic and the rocky particles—no free choice was given to the oil—no opportunity to select its natural partner was afforded—and failure resulted.

Everyone equally knows that subsequent to Frank Elmore's patent every flotation plant which has been erected depends for its success upon the use of a large quantity of water and an oil which will adhere to the metallic particles but not to the rocky particles. In every one of the plants without exception the oil is given a free choice in a perfectly mobile mixture of pulverized ore suspended in a large quantity of water. This complete invention cannot be better described than in the words of the claim of Frank Elmore's German patent quoted hereafter.

Having made this important far-reaching discovery, which may be described as "the selective action of oil in the presence of a large quantity of water," and which James Swinburne has described as "the work of a genius or a madman," it was not difficult for anyone with Frank Elmore's mechanical ability to design suitable apparatus in which to carry on the process as a continuous operation.

In a paper describing the Elmore process that C. M. Rolker read before the Institution of Mining and Metallurgy in April 1900, he said: "The mechanical contrivances brought into action by the inventor are excellently adapted to the work demanded, and bespeak very careful thought, as well as patient, systematic, and highly intelligent work. Seemingly insuperable mechanical difficulties in the initial stage have been very ingeniously overcome, and the process has arrived at a practical working stage."

Now while the industrial plant at the mine before-mentioned continued to work successfully and give increased confidence as to the future of the process as a result of the trials on bulk parcels of ore from other mines, Wernher, Beit & Co., Mr. McDermott, and the brothers Elmore formed a private syndicate in which they were the sole shareholders for the purpose of carrying on the development and introduction of the process. That syndicate hung out its sign early in the year 1901 at a demonstration works in London which was equipped with a complete crushing-mill and a full-size working unit of Elmore plant having a capacity of 25 to 30 tons of ore per day, to which was shortly added another unit, bringing up the capacity to, say, 50 to 60 tons per day. This works was maintained with a large staff and was open to all interested to see the process in practical operation. The visitors' book contains the

I say that in those words is to be found the whole sub-

names of most of the engineers and metallurgists of note resident in this country or visiting from abroad. It was situated in the east end of London and was so popular as a place of pilgrimage for professional men that it became known as the "metallurgical Mecca."

A conservative estimate compiled from the works records shows that during the period 1901-1915 some 4500 to 5000 samples of ore from different mines in various parts of the world were tested on a small scale and about 150 bulk parcels of ore varying from 5 to 100 tons each were treated under working conditions in a full-size commercial unit of Elmore plant.

It was in the year 1901 that the syndicate first issued literature describing the process and calling attention to its possibilities. About 50 different pamphlets in seven different languages were published and widely distributed—to the extent of about 125,000 copies. It is probably true to say that in practically every mining country in the world the technical press contained articles describing the process and indicating possible lines of application.

The process was investigated both at the demonstration works in London and in the working-plant at the mine on behalf of intending users by a number of well-known independent engineers. The result of this propaganda was that up to the year 1904 about 30 units of plant had been supplied to ten different mining companies. The aggregate capacity of these 30 units was, say, 300,000 tons of crude ore per annum. They were applied to ores containing copper, pyrite, gold with iron pyrite, copper-gold-silver, telluride of gold, and silver-lead ore.

I have elaborated this part of my narrative because the period I am now dealing with is the turning-point in the history of this now great industry. I am desirous of emphasizing that prior to Frank Elmore in 1898 nothing practical or commercial had been accomplished, that by his fortunate discovery of the selective action of oil in the presence of a large quantity of water success was immediately achieved. This is proved as shown above by the investigation of independent engineers and by the large commercial installations made. Moreover, it is accentuated in a remarkable way by the fact that every flotation plant in operation at the present time is characterized by the use of a large quantity of water with the crushed ore.

It will be noted that I have put this period of active development between the date of Frank Elmore's first patent and the year 1904. I have done this purposely because I wish to deal with his inventions of later date and their development separately; but for the purpose of keeping the record in order I wish to turn back on our high-road of flotation to the year 1901, when my own minor contribution was made in the form of the discovery that a slight acidulation of the mobile mixture of ore, water, and oil greatly enhanced in some cases the selective action of the oil. I wish to state here also that during the progress of the development of the Frank Elmore invention, most exhaustive trials were made with various kinds of oil and mixtures of oils, vegetal,

animal, and mineral, of all degrees of viscosity from solid or semi-solid waxes to the lighter spirits such as turpentine, benzol, etc., etc. Nor were the investigations confined to 'oils' alone; experiments were made with many substances which for the purposes of this process acted in a similar manner to oils.

The effect of various degrees of temperature was studied and much attention was given to the question of the degree of agitation as affecting the results obtainable on different kinds of ores. Many forms of mixers were designed and employed, giving degrees of agitation or mixing from the most violent turbulence down to a mere gentle stirring. It is worthy of note here that in the London testing works in the year 1902 a Gabbett mixer (a vortex-mixer giving a violent agitation with the incorporation of large quantities of air) was employed at the suggestion of Mr. McDermott in an elaborate series of tests carried out on telluride of gold ore from the Lake View mine in Western Australia. At the end of 1902 a working-plant was sent to that mine in which the ore, water, and oil passed through high-speed centrifugal pumps used with the object of securing the most violent agitation of the oil with the particles of mineral and rock freely suspended in the large quantity of water employed.

At these London testing works and in the various mine installations observation was constantly made of the various forms of 'float' which were obtained. It was noted for instance, that varying proportions of the mineral would be buoyed up or floated to the surface or maintained on the more or less quiescent surface of the water by (1) a large excess of oil, (2) a mixture of oil and air, (3) individual oil-coated particles floating by 'surface tension,' (4) a froth of oil-coated mineral particles and air, (5) individual oil-coated particles or aggregations of oil-coated particles attached to separate air-bells.

Sometimes all of these phenomena could be seen in different parts of the same apparatus. It was also remarked that with certain proportions of some kinds of oil some minerals would form aggregations which would sink. But it is to be remembered that all such phenomena were ancillary, subsequent to and dependent upon the differentiation of the mineral and rock particles resulting from the previous selective action of the oil employed.

Various proportions of oil were tried—the investigations were even carried so far as to prompt trials with ground cork, chopped straw, and similar buoyant materials which had been previously coated with oil or grease. It was found that by mixing such materials with a mobile mixture of ore and water quite a good extraction could be obtained in some cases—each little ship floating with its cargo of mineral, or being grouped together with air-bubbles making a froth.

It is probably true to say that up to 1904 all commercial working-plants had been operated with a large quantity of oil. That is, instead of buoying up the previously greased mineral particles by means of air-bubbles in the form of a froth, as he did in his later patents, Frank Elmore up to, say, 1904 preferred to employ an

excess of oil with which was incorporated a large quantity of air for this purpose.

In the interests of historical accuracy I cannot too strongly insist upon the basic fact that the flotation process consists essentially of two steps: first, the *differentiation* of the two sets of particles by causing one set to be wet with oil and the other set to be wet with water in the presence of a large quantity of water, so that the oil has the best possible opportunity of exercising its free choice; second, the subsequent *separation* of the differentiated particles.

It is perfectly obvious that the first step—the differentiation—is the all-important one because the second step, the separation, cannot be made commercially unless a practical way of securing the requisite differentiation has first been devised and applied.

It is with probably a better, fuller, and more intimate knowledge of all the facts and people connected with this business than anyone else possesses that I unhesitatingly claim for Frank Elmore the discovery and invention of this essential principle and process—the principle and process which has been incorporated into every flotation plant which has up to the present time been worked on a practical scale.

I wish it to be understood here that I am not saying that ingenuity, and even invention, may not have been and may not still be exercised in improving methods of *separation* of the differentiated particles, but I do say that whatever the method of separation employed, be it 'froth,' 'surface tension,' 'greased cork,' or what not, the pith and marrow of Frank Elmore's basic invention has first been employed to render that separation practicable.

Precisely the same argument applies to my 'acidulation' patent of 1901—it was a mere addition to or improvement upon Frank Elmore's basic invention of 1898, it was a way of enhancing the selective action of oil in a mobile mixture; of increasing the power of differentiation of the oil in the presence of a large quantity of water. Exactly the same thing may be said of my patent of 1901 for the use of a greased belt for collecting the greased mineral particles and separating them from the non-greased rock particles. Neither of these inventions could be put into practice except in conjunction with, or as an addition to, the fundamental process of selectively greasing the mineral particles.

At this point it may be useful to note that my 'greased belt' patent of 1901 is the first publication showing an apparatus in which small quantities of oil *must* be used—it is not capable of practical use with large quantities of oil; and while on this point I would like, in emphasizing the date, to quote a few words from Frank Elmore's patent—vacuum process—of 1904.

After referring to processes for separating ores by means of tar or oil, soap or the like, or with an alkali, an acid, air, or gas, he goes on to say: "By the present invention all such processes are improved, *more particularly in the respect that a smaller proportion of the added substance, such as oil or acid, may be used*, by conducting them wholly or in part under a reduced pressure.

For instance, a vacuum or partial vacuum may be maintained in the separating vessel or chamber."

I have dealt rather fully with these questions of degree of agitation, quantity of oil, and condition of float, and quoted dates and references because for some considerable time past, in absence of definite public statements to the contrary, increasing claims to priority have been and are being made without any proper justification. I would like to record in unequivocal terms that prior to the filing of Frank Elmore's vacuum patent of 1904, he and I, and those associated with us, were fully aware of the advantages and drawbacks connected with the use of a more or less violent agitation and of the effects of small and large proportions of oil.

I do not wish it to be supposed that I am claiming that my 'greased belt' patent of 1901 ever came into general use or that small proportions of oil were common at that date, but I do wish to be on record definitely and emphatically that from the date of Frank Elmore's vacuum patent (August 1904) minute proportions of oil with violent agitation were in constant use producing a 'froth' in industrial plants on a large scale.

It may be well to set down the fact that these vacuum plants have *never* been employed with a large proportion of oil. As is well known, in such plants the flotation of the greased mineral particles is secured by the attachment of bubbles of air or gas. In every one of the, say, 150 units of vacuum plant supplied (of an aggregate capacity of about 2,250,000 tons of ore per annum) the flotation of the concentrate results from the use of a violent agitation, a minute proportion of oil, and the production of a froth.

It will be understood that I make these statements in refutation of many claims made in connection with the patent dated April 12, 1905, applied for by Sulman, Picard, and Ballot—eight months after the date of application of Frank Elmore's vacuum patent.

As everything which followed the Frank Elmore patent of 1904 seems to me to be in the nature of ordinary development of working details, I do not at present purpose to follow the technical side of the matter further, believing that what I have already set out is sufficient to enable unbiased investigators to properly and fairly apportion the credit in this matter.

These notes—incomplete and abridged as they are—are already longer than I had intended, but as there are several points of interest that have been misunderstood in connection with the seemingly interminable litigation, I venture to draw still further on the patience of my reader.

Toward the end of the year 1901, Messrs. Hay, Webster, and Ballot entered into an agreement with the Ore Concentration Syndicate Limited (owners of the Elmore patents) under which those gentlemen in consideration of certain payments secured an option on the Elmore patents and all improvements for Australia. The option was for six months, with right to them, on making further payments, to a further six months. Messrs. Hay, Webster, and Ballot were to be entitled

during the option period to send parcels of ore for testing to the Ore Concentration Syndicate works and they and their workmen, experts, and agents, were to have free access to and liberty to remain on the Syndicate's works for supervising the tests. The Syndicate, when required, was to give to Hay, Webster, and Ballot all the information in its power respecting any tests made; and to furnish information as to the plant, the oil, and other things necessary for the treatment, and were to supply copies of reports made by its experts on its inventions in any part of the world, etc., etc.

One of the considerations to the Ore Concentration Syndicate under this agreement was contained in Clause 7, of which the following is an extract: "From and after date hereof" Messrs. Hay, Webster, and Ballot "and their assigns * * * shall from time to time, after making or becoming entitled to any improvement in or addition to the said invention or process or any discovery useful for separating metallic from the rocky constituents of ores by the use of oil forthwith give notice thereof in writing to" the Elmore Syndicate, "and shall upon demand * * * communicate and explain * * * such improvement, addition, or discovery, and the" Elmore Syndicate "shall be entitled to every such improvement, addition, or discovery whether the same shall be patented or not."

Under this agreement Hay, Webster, and Ballot exercised their rights of option during a period of 11 months. Ballot or his consulting metallurgists, Sulman & Picard, attended at the works on almost every working day during that period. As they were treated with the greatest frankness they became fully acquainted with every detail of the process, plant, and working.

The option was not exercised.

Ballot's name was subsequently joined with that of Sulman & Picard on the patent of 1905 and he and Webster, with some friends, formed a syndicate, the original of the present Minerals Separation Limited, which acquired the Cattermole, Froment, and Sulman, Picard, and Ballot patents.

Legal action was started by the Ore Concentration Company (owners of the Elmore patents) in 1905 to enforce the provisions of Clause 7 of the agreement quoted above. The Ore Concentration Company lost in the first Court; they appealed asking for a new trial which was granted. After the hearing of the new trial had proceeded for several days the judge, as I understand it, raised the question as to what the position would be if Ballot had "made or become entitled to the improvements in or additions to the said invention," not on his own behalf but on behalf of the Syndicate of which he was a member.

In view of the fact that the judge was Mr. Justice (now Lord) Parker, doubtless the "Law" thus hinted at was very good; but the common-sense view of the matter may be left to the judgment of common-sense people.

At any rate, on this hint the parties to the suit consulted and the action was "settled by consent and by way of compromise and settlement of all claims arising

in respect of agreement of October 8th, 1901, both past and future, all proceedings stayed, each party paying his own costs."

There was not in this suit any question of validity of Elmore patents, and presumably because of that fact the proceedings have not received the attention they deserve. The case is quoted simply to draw attention to some interesting evidence given and as showing how extremely difficult it is for an inventor to protect himself.

The clause was drawn by one of the best legal firms in this country, and I believe the real meaning and intention of it is perfectly clear to the ordinary business man. Yet it took five judges, three courts, twelve learned counsel, and four firms of solicitors a period of two years to bring about the settlement above stated.

What a splendid justification for Molière's lines:

"There, take," says Justice, "take ye each a shell;

We thrive at the Law Courts on fools like you.

'Twas a fat oyster! live in peace—adieu."

Another protracted law-suit was commenced by the Ore Concentration Co. in Germany in the year 1906. It took the form of an opposition to the grant of a German patent applied for by Messrs. Sulman, Picard, and Ballot. The application was for a patent in substance the same as the main Minerals Separation patent in England.

The fight lasted for about three years; after hearing evidence and seeing experiments made, the German Patent-Office decided in July 1909 that the application of Minerals Separation disclosed no new feature to differentiate it from Elmore's earlier patent and consequently refused the grant of a patent to Minerals Separation.

I believe this suit is little known and attention is called to it in view of the importance of the decision arrived at by the German Patent-Office and because of the completeness of the historical record set out in the documents.

The following is a translation of the claim in Elmore's German patent:

"Process for the separation of the metallic from the mineral constituents of pulverized ore by mixing the latter with water and oil, characterized by the addition to the pulverized ore of water in at least such quantity that the mixture becomes very mobile, and the pulverized ore is freely suspended in the water."

Then, in the year 1907, Minerals Separation entered action against the Ore Concentration Company alleging infringement of Froment's patent (which had been bought by them for a trifling sum), dated 1902. The defence was anticipation by Stanley Elmore's acidulation patent of 1901 and prior public use by the Ore Concentration Company. The result was that in 1909 the Minerals Separation company gave notice that they wholly discontinued the action and paid the costs of the Ore Concentration Company.

In view of the decision of the German Patent-Office, establishing priority of the Elmore patents in which small quantities of oil and violent agitation are used over the application of Sulman, Picard, and Ballot, an

action was commenced in Germany in 1910, by the Ore Concentration Company (1905) Ltd. against the Metallgesellschaft claiming that concentrates produced in Australia by methods disclosed in Elmore's German patents and imported into the German Empire constituted an infringement of Elmore's rights under German law.

This action has not yet been prosecuted to a conclusion because of the difficulty first experienced of establishing the necessary exact legal chain of evidence connecting any particular sample of concentrate found in Germany with its production by the Elmore process in another country.

Similar actions will doubtless be started in connection with the importation of infringing concentrates into other countries.

To attempt anything like a comprehensive review of all the subsequent litigation the owners of the Elmore patents have been forced to commence in an endeavor to maintain the rights to which by general consent of a large number of independent authorities they are justly entitled, would occupy more of my time and more of your space than either of us might be inclined to give.

I would only like to say that throughout the whole of this weary litigation extending over years in England, Australia, and Germany, the validity, novelty, and utility of the Elmore patents have invariably been maintained, but by the incredulity and failure to grasp the importance of the Elmore invention by the mining industry in the early days have we as inventors and our sympathetic financial supporters been deprived of that monetary reward which should have been the result of the successful development of a revolutionary metallurgical process.

As it is, the world has been enriched by millions, the inventors have devoted 18 years of their lives to the development and introduction of this process, and they and their friends have expended some £200,000 in cash, without reasonable recompense of any kind. This record in a particular instance is distinctly discouraging to inventors and to those who are tempted to finance new inventions.

My own experience prompts me to say that till adequate reforms are introduced in the procedure by which patents are tested in the courts, till these courts are assisted by competent and independent skilled referees in matters of a scientific and technical character, in lieu of the present practice of calling a number of expert witnesses on each side whose evidence is generally conflicting and irreconcilable, it is an inhuman cruelty to foster in students a desire to cultivate any powers of inventions they may possess.

The above is my present contribution to the history of this invention. Some day I may find leisure to elaborate it into a real history worthy of the subject.

EXPORTS of tungsten ore from Japan in 1915 were as follows: United States, 85 tons; France, 214; United Kingdom, 110; total, 409 tons. The estimated shipments for this year up to July 20 were 480 tons, most of this amount being sent to the United States.

Mineral Industry of Japan

An interesting survey of the mineral industry during the past year as influenced by the War is given by Mr. Isobe, director of the Mining Bureau in the Japanese Department of Agriculture and Commerce. He says that the total value of the mineral output during the year amounted to 175,950,000 yen (1 yen = 50 cents), exclusive of the production at the Government Iron Works. This is a gain of 20,920,000 yen over the preceding year. The total value of metals produced amounted to 35,730,000 yen, or 57% above the previous year's figure. Non-metallic minerals on the other hand fell off by 15,280,000 yen mainly because coal was very inactive.

Gold and silver showed an increase by 16 and 5%, respectively, because of more active work at some mines. Copper was hard hit at first, but in March, 1915, trade was resumed owing to the demand by munition makers. Though the increase in production amounted to 7%, the increase in the total value is more than 37%.

Antimony showed an extraordinary boom in prices owing to the ever-increasing demand from munition makers. The volume of the output increased by 200%, while the value gained 8750%. Zinc went through the same vicissitudes as antimony, and at the close of the year the output showed an increase of 206% and the value, 805%. The completion of the plants of the Osaka Zinc Industry Co. and the Miike Zinc Refining Works during the year was largely responsible for this increase in the output. Coal was hard hit by the War, and restriction of production was made by Kyushu mines. The output decreased by 8% and the value 19%. Petroleum witnessed an increase of 11% in the output owing to a renewed gusher at Kurokawa, Akita, but the market presented no encouraging signs. Toward the end of the year there was some activity noticed, but the gain in value was only 5%. Sulphur decreased by 3% in the output and 5% in value, though toward the close of the year the market displayed a sudden activity, because all through the early period of the year production was heavily cut down at Hokkaido owing to the dullness of the market. —*Far Eastern Review*.

SOME Chilean nitrate statistics are as follows, according to a Consular Report, dated July 26:

	Quintals 1913-14	Quintals 1914-15	Quintals 1915-16
Production	62,322,617	34,091,243	57,715,614
Exports	58,751,291	32,070,714	55,285,814
To Europe and Egypt.....	44,534,131	16,939,650	29,017,777
To United States.....	12,290,782	13,437,418	23,484,842
East coast	11,222,657	12,295,221	20,390,839
West coast	1,068,125	1,142,197	3,094,003

Periods are for the years ended June 30. A quintal weighs 101.4 lb. Ordinary 95% nitrate is selling for \$1.77 per quintal, or \$35.40 per ton.

APPROXIMATELY one-half of the gold and silver contained in the ores of the Nevada Consolidated at Ely is recovered with the copper.

Amortization and Depreciation

By Robert S. Lewis

In this age of efficiency, little cause should remain for criticizing the reports of mining companies. Nevertheless, there is a noticeable lack of completeness in the figures of operating cost given by many of them. Allowances for amortization of capital and depreciation of plant are conspicuous by their absence, yet without them the true cost of mining and milling cannot be determined.

If a certain sum be invested in an enterprise that pays dividends for a number of years and then suddenly fails, the investor's gain or loss, as commonly computed, would be equal to the dividends paid less the sum invested. Assuming that the dividends exceeded the investment, they doubtless would have been considered wholly as income and not as composed partly of income and partly of a return of capital, which is their true nature.

When provision is made for the return of the sum invested, the process of redemption is called amortization of capital. Skinner¹ applies the term 'amortization' to the extinction of an interest-bearing debt, such as a bond issue, by equal annual payments or installments, but the question of interest complicates the case and need not be considered unless it is required. It is obvious that the life of the investment must be either known or estimated. This element of time is important and later will be considered at greater length.

Since a mine is a wasting asset—one that is of value only while being consumed—and is therefore of limited life, sound finance requires that the price paid should be returned to the purchasers at the expiration of the life of the mine, and that the profits from operation, in excess of this sum, should yield a satisfactory rate of interest. It is plain that both amortization and interest must come from profits, which are returns from the enterprise over and above the cost of operation, as this term is usually considered.

Hoover² states that it would seldom be possible to plan a definite policy of amortization, because the duration of the life of most mines is unknown, that mining companies never establish sinking-funds for the amortization of capital, and that should such a procedure be followed stockholders would prefer to do their own re-investing. However, several companies are now virtually amortizing their capital. Having recognized that their mines are approaching exhaustion they seek to prolong the life of the enterprise by purchasing other property. This practice is being adopted in the United States after having been applied successfully by English companies. Despite the great number of investors in mining shares,

it will be found that few understand the real nature of the income derived from their holdings and provide for amortization of investment; consequently a stopping of dividends means an impairment of their capital.

Two methods of calculating amortization have been used. The first creates a sinking-fund which will amount to the investment at the termination of its life.

Let C = the capital invested,
 r = the rate of interest that can be obtained on sinking-fund,
 n = the life in years,
 S = the annual payment to fund for amortizing capital.

$$\text{Then } S = C \left[\frac{r}{(1+r)^n - 1} \right]$$

Example: If \$250,000 is paid for a mine having an estimated life of 15 years, and 4% interest can be obtained on the sinking-fund, the annual payment necessary to amortize \$250,000 in 15 years is

$$250,000 \left[\frac{0.04}{(1.04)^{15} - 1} \right] = 12,500 \text{ in round numbers.}$$

The second method meets the requirement that interest on the sum invested is demanded during the period of amortization. Part of each annual payment goes to pay interest and the remainder is used to reduce the principal. Since interest for the year is computed on the reduced principal, this interest charge grows less each year and the reduction of principal becomes more and more rapid.

Using the same notation as above, except that r is now the rate of interest demanded on the investment,

$$S = C \left[\frac{r}{1 - \frac{1}{(1+r)^n}} \right] \text{ or } S = 250,000 \left[\frac{0.04}{1 - \frac{1}{(1.04)^{15}}} \right]$$

For a more detailed example of this method see 'The Cost of Mining,' by J. R. Finlay, page 45.

Skinner³ defines depreciation as "the loss in value of physical property, due to use, which cannot be made good by current repairs." Fish⁴ views depreciation in the light of the equation:

$$\text{First Cost} - \text{Depreciation} = \text{Salvage Value}$$

The first conception is of interest to the manager of the plant, since the charge for depreciation is a charge against operation, while the valuing engineer is concerned with the second conception, as it enables him to put a price on the property should an appraisal be required.

Depreciation results from a number of causes, which

¹'The Mathematics of Investment,' E. B. Skinner, p. 114.

²'Principles of Mining,' H. C. Hoover, p. 44.

³'The Mathematical Theory of Investment,' by E. B. Skinner, p. 149.

⁴'Engineering Economics,' by J. C. L. Fish, p. 48.

may be classified under two heads: physical decay and functional decay. The first may be predicted with a fair degree of accuracy, but it is a more difficult problem to forecast functional decay, meaning either inadequacy or obsolescence. Inadequacy indicates that a machine is not capable of fully performing the function which it was intended, generally by reason of expansion of the enterprise. Obsolescence brings a decrease in value by reason of the invention of a better machine or the discovery of a process not requiring the use of that particular machine. For this reason a new machine may suddenly become worthless though it is in perfect physical condition.

When depreciation is applied to the separate departments or units of a plant it is called 'unit depreciation,' while total or composite depreciation is applied to the entire plant, and is always the sum of the unit depreciations. Thus it is plain that 'unit' depreciation may reach 100% of the original value, but 'composite' depreciation increases to a certain point, say 15 or 20%, beyond which it does not go owing to the renewal of the units of the plant. While operating efficiency is ultimately dependent upon depreciation, a superficial consideration would show little relation between them. Thus ordinary repairs might maintain a concentrating-table at 100% operating efficiency for several years, until suddenly, like the 'One-hoss Shay,' the table went to pieces and had to be replaced by a new one. If proper provision for depreciation had been made, the sum accumulated should pay for the new machine. It is short-sighted policy to refuse to recognize depreciation because present operating efficiency is high. Depreciation on mining property should be calculated on the basis of future replacement rather than on future sale.

When worked-out a mine has no value, but the plant on the surface—such as hoist, offices, mill or smelter—has a scrap or salvage value that is dependent upon condition. Where machinery has been in use for ten years or more, many engineers consider that it has no salvage value. The hard pace at which it has been driven, the long distance it would have to be transported to a new plant, and the fact that it is unlikely to be the most suitable machinery to use tend to extinguish its money-value. Second-hand mining machinery generally proves to be the most expensive that could be bought.

After a new plant has been brought into a condition of steady operation, current repairs reach an approximately uniform figure. There should be no great difference from year to year, though repairs tend to increase as the plant becomes older. However, the replacement of a large amount of equipment or the making of changes involving heavy expense would place too great a burden on the revenue for that year if written-off in one sum. It is the purpose of depreciation to distribute this expense over a number of years and thus maintain a fairly uniform charge against operation. The only expense properly chargeable to capital account is that which results in increased capacity and earning power. The replacing of several machines by one capable of

doing the same work, the elevating of grinding apparatus in order to obtain the proper slope for launders, in short, all expense necessary to keep the plant up to date and in proper operating condition should be charged to depreciation, and not to capital.

Except in rare cases, it is not possible to predict the life of a mine. Even where reserves have been blocked out sufficient to last for 15 or 20 years, as in the large copper mines, later developments may greatly extend this period. For this reason calculations on amortization and depreciation are largely tentative and may require subsequent modification, but such charges should be made if the real operating expense is to be ascertained. The elements entering into a particular case require careful study in order to make the estimate as reliable as possible. Changes may then be made when necessary.

The life of machines under given conditions may often be estimated quite accurately. The mortality-tables of life-insurance companies prove that reliance may be placed on the law of averages, though individuals show a wide divergence from the average. Having this in mind, the Railroad Commission of the State of Washington has constructed a mortality-table of structures that has been useful to them in their work of valuation. If mine and mill superintendents would keep detailed records of the machinery under their charge and publish the figures, depreciation would soon be recognized as a legitimate and necessary account instead of being accorded the erratic attention it now receives.

The importance of an account for depreciation is well illustrated in the paper by P. W. Henry⁵ where he states "that a proper depreciation charge may be equal to or greater than the direct cost per barrel, will doubtless surprise many investors in oil properties who consider only immediate expense and immediate profit without regard to the safety of the principal invested." In certain cases a fair depreciation charge would be 4% on the cost of oil-lands, 7% on the cost of field-equipment, and 10% on the cost of individual wells and appurtenances. Under the Income Tax Regulations of 1913, a depreciation charge for depletion of ore reserves may be made, not to exceed 5% of the gross value of the year's output at the mine. In addition, an allowance for depreciation of plant is permitted.

Actual depreciation does not follow any fixed law, but estimates made after a careful study of conditions are sufficiently accurate for practical purposes. Unit depreciation must first be found, and then the total or composite depreciation for the entire plant can be calculated. Since depreciation is based upon cost, only one kind, either physical or functional, should be used for a given unit, and this should be the greater of the two. The other is ineffective. Evidently total or composite depreciation would be made up from a number of unit depreciations, some of them physical and some functional, for all units would not depreciate in the same manner.

⁵'Depreciation as Applied to Oil Properties,' read at New York meeting of A. I. M. E., February 1915.

The most common methods of determining theoretical depreciation are given below.

STRAIGHT-LINE METHOD: This is the simplest of all methods, and has been much used because of the ease with which it can be understood and applied. It is based upon the assumption that the annual charge for depreciation is the quotient that results from dividing the cost by the life in years.

Let V_c = the cost,

V_s = the salvage-value,

n = the life in years,

D = the annual depreciation charge,

$$\text{Then } D = \frac{V_c - V_s}{n}$$

Assuming that a Chilean mill costs \$2000 and has a life of 10 years, the annual depreciation charge is $2000 \div 10$, or \$200. The annual charges are equal and no interest charges are involved, neither are logarithms required for the solution. However, as it is based on a fixed procedure, it does not show how the depreciation actually occurs nor does it consider various factors that may exert at any time a marked effect on the charge for depreciation. Then, too, unless a separate depreciation account is kept for each machine in question, constant reference to the original cost is required, since the yearly record of depreciation does not require that this figure be stated.

REDUCING BALANCE METHOD: This is another method that is not complicated by interest calculations. Using the same notation as above, the formula is $D = 1 - \frac{n}{V_c} \sqrt[n]{V_s}$.

D in this case is to be taken as the percentage by which the balance must be reduced each year. Since the problem is indeterminate when the salvage value is zero, a nominal figure such as \$1 should be used. Thus for the above example $D = 1 - \frac{10}{\sqrt[10]{2000}} = 0.5324 = 53.24\%$ = \$1064.80 for the first year.

It is evident that this formula gives a diminishing annual charge for depreciation, which is claimed to be in accord with economic facts. Since the yearly repairs usually increase as the machine grows older, the annual charge for repairs plus depreciation against operation becomes nearly constant. However, this method involves a complicated mathematical calculation and the rate obtained gives little indication of the period required to write-off the investment. Furthermore the high charge during the early years of operation may be serious for a new plant, when profits are often meagre. Though the high rate obtained must be far in excess of the actual rate of depreciation, it is claimed that this rapid writing-off removes the possibility of a failure to establish an adequate reserve, but there is danger of creating a secret reserve from this under-valuation of assets.

SINKING-FUND METHOD: This method has been advocated by many writers. As the name indicates, equal annual installments are set aside at compound interest until the accumulated sum is equal to the depreciation. The longer the term during which the fund is accumu-

lating, the larger become the contributions earned from interest. Thus it would seem that the cost of creating such a fund would grow less with the increase in the number of years required. As the contributions to the fund are necessarily taken from the business, the business must not be very prosperous if money can earn more when placed in a sinking-fund than if used in the business.

$$\text{The formula is } D = V_c \left[\frac{r}{(1+r)^n - 1} \right]$$

where D is the annual contribution to the sinking-fund and r the rate that is paid on the fund. Returning to the example given above and assuming 4% on interest,

$$D = 2000 \left[\frac{0.04}{(1.04)^{10} - 1} \right] = \$166.66 +. \text{ This is the same as the first formula given under amortization.}$$

ANNUITY METHOD: In the methods thus far discussed, the question of interest on the investment has not been considered. In the annuity method a constant sum is set aside each year. This sum when deducted each year from the remainder of the investment plus interest will write off the investment and also return interest on the investment during the period in question. $D = (V_c - V_s) \frac{(r-1)}{(r^n - 1)}$. In this case r = rate plus 1. Since $V_s = 0$, $D = 2000 (1 + 0.04)^{10} \left[\frac{1.04 - 1}{1.04^{10} - 1} \right] = \$246.66 +.$

Since the interest is calculated each year on the reduced value, it follows that as the interest charge decreases the allowance for depreciation necessarily increases, since the sum of the two equals the yearly payment. The need for allowing for interest is more apparent than real. In any properly-conducted business, part of the net profit represents interest on the investment, and to require interest when the depreciation account is created and maintained from profits is to duplicate the charge for interest.

The results of calculating depreciation by the above methods have been plotted in the accompanying chart.

The curves show the total depreciation fund as it accumulates from year to year. Two other methods should be mentioned in passing: the equal annual payment method proposed by the special committee on valuation of the American Society of Civil Engineers, and the unit-cost method. Both are more complicated than the methods given above. They are fully explained in Salier's 'Principles of Depreciation,' to which work I wish to acknowledge my indebtedness.

Cupellation Losses in Assaying

*This subject has occupied the attention of many assayers, especially where silver ore and bullion are being tested. The results tabulated and summarized in the 54 pages of this publication are those of H. T. Mann and C. Y. Clayton, assisted by J. A. Taggart and A. F. Karte. The investigation was a thorough one.

Temperature, material in cupel, impurities, and other factors affect the loss of precious metals. In their experiments, the authors weighed a certain amount of silver foil and wrapped it in lead foil, the latter being weighed to the nearest half gram. A muffle in a gasoline furnace was used for cupelling. Each test consisted of

The charge for each cupel was 20 gm. lead and 20 mg. silver. The cupels used were of boneash, half cement and half boneash, cement base with boneash top, cement, Morganite, Braumite, and three patent cupels.

The effect of the amount of moisture and the hardness of cupels on the silver loss was next investigated. Five sets of cupels were made from boneash containing 5, 8, 12, 17, and 22% of moisture, respectively. One lot was made very soft, the next soft, followed by ordinary, hard, and very hard. Cupellations made in these showed that the amount of moisture and their hardness had little effect on the loss of silver. The very soft cupels finished a little ahead of the hard ones.

Other tests proved that the surface condition of the

CURVES SHOWING LOSSES OF SILVER DURING CUPELLATION, USING DIFFERENT MATERIALS.

five rows of six buttons in each across the muffle, the first row three inches from the front, this row only acting as a shield for the others. The cupels were heated to 925 or 950 °C. before placing in the buttons. Until all the buttons were molten the muffle door was kept closed. Then it was opened, and the temperature of the cupellations lowered by reducing the muffle temperature, also by 'coolers' put in the muffle. 'Feathers' of litharge formed around the cupel. This heat was held until a minute before the 'blick,' when the coolers were withdrawn and the furnace temperature raised so that the cupellations finished at between 850 and 900°C.

Of the boneash used in the cupels 21.7% passed through a 260-mesh screen, while 14.2% remained on 65, 22.5% on 100, 9.3% on 150, and 16.2% on 200-mesh.

*Abstract from Bulletin of the School of Mines, University of Missouri, at Rolla.

cupel has little or no effect on silver losses; that is, whether the surface was well glazed or rough.

It was thought that the size of the boneash may affect the losses, but many cupellations showed that, provided the boneash passes 60-mesh, the size of the particles makes practically no difference. The time of cupellation with different sizes of ash was almost the same.

The final experiments were made to determine whether any losses were due to the chemical composition of assay slags. The conclusion arrived at was that under ordinary conditions of assaying the chemical composition of the resulting slag has very little effect on the silver recovery, provided the four requirements of a good fusion are fulfilled, namely: complete decomposition of the ore, formation of a fluid slag, furnishing the proper amount of collector (lead) at the proper time, and keeping out of the lead button undesirable impurities.

Notes on Flotation

By Rudolf Gahl*

COAL-TAR AS FLOTATION AGENT

It was to be expected, when the flotation process was installed in our test-plant, that there would be ups and downs in the recovery because the process was rather new, especially in its application to chalcocite ores. For the month of June 1914, the recovery obtained in the test-mill showed a sudden drop, and the serious problem confronted us of establishing the cause and finding a remedy. Some of the flotation experts suggested that it might be due to the fact that a new shipment of cresylic acid might not fill the specifications of being 98% pure. We did not feel competent to say whether the impurities actually amounted to more than 2%. We were, however, inclined to think that perhaps cresylic acid, which is one of the products resulting from fractional distillation of coal-tar, might not represent the fraction most suitable for the flotation of our ores. Having no coal-tar available, we proceeded to make some by distilling a sample of ordinary New Mexico soft coal and separating the tar thus formed into the fractions distilling off at different temperatures.

Our facilities for testing oils were limited. The Minerals Separation representative did not believe in small-scale tests, and for this reason did not recommend experiments with small testing-machines. Nevertheless, it seemed desirable to have something with which to carry out small-scale laboratory experiments. Dr. L. D. Ricketts, who was aware of our troubles and realized the importance of such tests, was kind enough to send us a little electrically-operated emulsifying machine, which served admirably for qualitative tests. We also built a testing-machine based on the principle of the standard Minerals Separation machine, with the difference, however, that instead of sending the pulp from one agitating-compartment to a spitzkasten and then into another agitating-compartment and spitzkasten, we made the pulp return from the first spitzkasten to the original agitator, forcing it to revolve in a closed circuit. Lately, a machine based on the same principle has been put on the market and is sold by the Denver Fire Clay Co. Thus, we had a chance to try the different fractions of our home-made coal-tar.

The chemist who conducted these tests (Mueller) hit on the idea that it might be well, in addition to trying the different fractions, also to test the coal-tar as a whole. The results were surprising, since they showed that by the addition of crude coal-tar we could effect a

greater recovery than we were able to obtain by the use of highly refined cresylic acid. From this point dates our experience that it is better to use coal-tar than soluble flotation agents like cresylic acid to save coarse mineral. Cresylic acid is an extraordinarily good agent for producing froth, but the froth does not seem to have as much carrying power for coarse mineral as that produced by coal-tar. Not all coal-tars are equally good for this purpose. Tests in laboratory machines easily show the difference between coal-tars of different origin.

It is difficult to utilize coal-tar in plants using flotation supplementary to gravity concentration, on account of the fact that it is not easy to effect a good amalgamation of tar with the pulp in agitating-tanks, and even in mechanical flotation-machines. The use of coal-tar lends itself very well indeed to the system of feeding tar into the grinding machines, a system that, as mentioned above, had been worked out in our small test-mill and patented by G. A. Chapman.

The company is indebted to Mr. J. M. Callow for proving the merits of coal-tar creosote as a flotation agent by using it in his demonstration plant at Inspiration. After we had established the value of coal-tar by laboratory tests, and while efforts were being made to obtain it commercially, he applied creosote successfully. We have continued to use it for a long time, mostly in combination with coal-tar, and have only recently dropped it, as we find crude coal-tar cheaper and better.

INFLUENCE OF IRON ON FLOTATION

While these tests were in progress, we made another useful discovery. In our tests on the most economical way of reducing the ore to the fineness necessary for flotation, we had, among other machines, a ball-mill in competition with pebble-mills. In the ball-mill, steel balls performed the duty that in pebble-mills was done by flint pebbles.

For a while, the ball-mill discharge was treated on one flotation machine, while the pebble-mill discharge was treated on a group of others. While this flow-sheet was being followed, we thought we noted that a flotation machine treating the ball-mill product showed the influence of the primary slime to a less extent than the flotation machine treating the pebble-mill product. In a discussion with Dr. Ricketts and Mr. Mills, the question was raised as to whether the iron introduced in the pulp by the attrition of the balls might not have something to do with the fact. The question was accordingly made the subject of some laboratory experiments. The results of a series of such experiments are represented in Table I herewith, and proved conclusively that the iron had a beneficial influence on flotation in counter-

*Excerpts from paper entitled 'History of the Flotation Process at Inspiration,' to be presented at the Arizona meeting of the American Institute of Mining Engineers (September 1916).

acting the harmful effect of the primary slime. This discovery was one of the inducements for installing ball-mills in the big concentrator plant, while originally pebble-mills had been considered for this purpose.

proved by the use of the magnet. If necessary, the effect of the iron could be increased by removing the iron contained in the tailing by means of electro-magnets and returning it to the mills or the flotation machines.

L30	750	1 10	12 75	83	5 06	4 20	32 9	Identical conditions as L27 and L28 but added 10 g. zinc filings.

We have not yet reached a point where we can safely give the reason for the action of the iron introduced into the pulp. It is sure, from the experiments, that the same results as by grinding with balls could be obtained by introducing the iron in finely divided form, say in the form of filings, into a pebble-mill pulp. We supposed for a while that the metallic iron might react on the impurities contained in solution in the mill-water and introduced therein with the primary slime. We find, as a matter of fact, that our ore contains little in the nature of soluble salts, and that whatever it does contain is mainly confined to the primary slime. For this reason, in laboratory tests we have tried repeatedly to substitute pure water for the water contained in the pulp. In every case, we have noted some improvements in results. We have also found that when we separate the water from the refractory pulp, treat it with iron filings, and add it to the original pulp again, we get a certain improvement in the recovery, but we have not been able to get an improvement equally as good as that obtained by direct introduction of finely-divided iron. For this reason, we have often thought that the effect of iron is physical rather than chemical. The iron exists in the pulp, at least partly, in the metallic form, as can be

ore containing a high amount of oxide, such as surface ore, is correspondingly lower. We have worked in the laboratory with the object in view of increasing the oxide recovery; for instance, by adding certain chemicals to the pulp, but we have not yet applied this method to

an operating scale, nor have we decided on using one of the other methods applicable for this purpose, such as leaching.

The table shown above gives an average screen-analyses of the feed and the general tailings of the In-

spiration concentrator for the months of March, April, and May. A segregation is made in the copper assay between sulphide and oxide copper, because, considering the present stage of the art, we feel satisfied with our work whenever the sulphide copper content of the mill-tailing is low. As will be seen from the tabulations, a better recovery is made on the -200 material than on the coarser constituents of the ore, which proves the point that for ores of this character sliming is no longer to be feared. There was little variation in the copper-oxide content of the tailing from the material of different sizes coarser than -200 mesh.

OIL CONSUMPTION

Experience has shown that we consume up to $1\frac{1}{2}$ lb. per ton of ore. At present, the oil mixture contains around 95% crude coal-tar and a little less than 5% of oil derived from the dry distillation of wood.

The different tars that we have tested during the operation of our mill have shown greatly varying qualities as far as their flotation value is concerned. The first tar that we used was home-made from domestic coal, and happened to be a serviceable flotation agent. Since that time, we have tested tars from several States. We have obtained satisfactory tar-products from New Mexico, Colorado, Missouri, and Illinois. These States furnish at present as much as we need for our consumption. For awhile, it seemed possible that we might have to import from a long distance the large quantities of tar that we require. During that period we tried to find substitutes, and looked especially toward the utilization of fuel-oil for this purpose, but we have not been able to get as good results with any kind of fuel-oil as with crude coal-tar.

Our experience is that we can get along with coal-tar alone. It is beneficial, however, to add wood-distillation products in small quantities, for instance, those containing pine-oil. While coal-tar makes a strong and heavy froth, such as appears to be required to keep coarse mineral particles in suspension, the wood-distillation products have the characteristic of producing a multitude of bubbles, such as seem necessary to furnish the large surface required to save the finest mineral particles. Because the finer ore particles expose a large surface, it is evidently necessary to produce a correspondingly large surface of froth in order to save them by flotation.

OPERATING COST

The number of men necessary for the operation of large flotation machines is remarkably small. At the Inspiration plant, one operator supervises four sections of flotation machines. Two Mexican helpers assist him in washing the bottoms, thus insuring a free passage of air through the porous medium. At the prevailing high prices of American and Mexican labor, this means an expense of somewhat more than 1.5c. per ton of ore treated. The total expenses representing flotation proper were as follows for the months of March, April, and May, 1916:

	Cents per ton
Labor	1.62
Oils	1.65
Other supplies	0.35
Power	2.14
Total	5.76

The subsequent table treatment of flotation tailings, the filter treatment of the concentrates and other operations connected with the process of concentration, belong more or less to flotation treatment, and their expense should also be considered when the cost of the flotation process is to be established. The total milling cost, exclusive of crushing and grinding, has been for the past few months in the neighborhood of 20 cents. When the cost of crushing and grinding is included, the cost is about 40c. per ton of ore. Royalties for the use of the flotation process are not included in any of these cost figures.

Iron as a Barometer of Industry

There is such a disposition in some quarters to regard the activity of the iron and steel industry as being based chiefly on the War demand for steel, it might be inferred that iron is not at this time the barometer of general trade; but the statement can be defended that iron and steel activity is at this juncture as close a reflection of general trade activity as has been the case at various times in the past. The production of steel ingots is at a rate considerably more than 40,000,000 tons per year, against only 30,000,000 tons in 1912 and 1913, hitherto the best years, and the War demand for steel does not account for all of the excess tonnage. Another and very important factor must be considered. There have been times when such general business activity as existed ran largely to new construction work, a line in which steel is particularly prominent. At such times the steel industry was more active than were many others, and if taken as a barometer it rather exaggerated the degree of general prosperity. At the present time the divergence is in the other direction. The employment of steel for strictly new construction is relatively small, and the consumption of steel for various miscellaneous uses, more directly and closely associated with the activities of the people, is relatively large. The function of the barometer, however, is not to tell of an existing condition, but to furnish means for a forecast, and it may be inquired what light the state of affairs in the steel market throws upon the question, how long the War is to last and how long business activity is to last. If one is to judge by the attitude of buyers of steel he may be confused, for some buyers are taking a decidedly conservative, if not pessimistic, view of the future of their particular lines, if high prices for steel are to continue indefinitely. Others are buying with confidence. If we are to judge by the attitude of steel producers there is no occasion to be confused. The steel producers are engaged in new construction, and prosecuting it when costs are extremely high.—*The Iron Age*.

Sinking Through Sand

By Edward A. Sayre

*A common method of sinking through difficult ground employs a steel shoe pushed ahead of the shaft-timbers; another is the drop-shaft method. These two methods were used at the Eagle No. 3 mine, Des Moines, Iowa, and the following data show the relative cost of the two methods under the same conditions. The material to be penetrated was 73 ft. of drift and sand, including several clay streaks.

STEEL-SHOE METHOD. The method of sinking the main shaft by the steel-shoe method was to agitate the sand and force the shoe through it by means of jack-screws. Two methods were used to agitate the sand. First, while the men could reach the bottom of the shoe, they stirred the sand with spades. Later the pumping system was used. The discharge of the No. 6 Cameron pump could, when desired, be sent through five $\frac{3}{4}$ -in. pipes, and the five jets of water could be played upon the sand at the bottom of the shoe. It was found that these jets would agitate the sand sufficiently to permit the jack-screws to push the shoe down, except when the sand was at too high a level inside the shoe, in which case sand would have to be excavated before the jet process could be resumed. In using this process the men would stir the sand with the jets for about 10 min., and then tighten the jack-screws. When sufficient space was obtained between the timbers in the shoe and the curbing above, the two jack-screws of one side were removed, and timber put in place on top of the timbers in the shoe, and then the other jack-screws were moved. An advance of 18 in. per day was exceptional, more often it was less than a foot.

Necessarily some sand had to be excavated. This tended to cave the dirt around the shaft, which in turn caused an excessive down pressure and broke the curbing. An attempt was made to overcome this by supporting the curb with I-beams and cables from the surface. Ten 12-in. beams were supported on cribs at the surface, and ten 8-in. beams were swung under the angle below the ties, being connected by twenty $\frac{3}{4}$ -in. steel cables. When the sinking was resumed, the curbing continued to break, the I-beams bent, and two cables were broken. Since it appeared impossible to hold the curb, it was decided to timber the shaft solid from the 8-ft. level (where the most uniform break occurred) to the bottom of the shoe, and then drop this portion of the shaft through the remaining 5 ft. of sand.

To do this, the ties were driven back into the wall and solid timbering put in between the shoe and the upper curbing of the shaft. The entire shaft curbing from the 8-ft. level down was then tied together with 2 by 6-in. stringers. At the 8-ft. level planks were spiked to the lower curb, the upper ends projecting above the break preventing the loose material from falling. The

jet system, using occasional excavation of sand, was resumed, and the shoe, with 50 ft. of curbing, was lowered.

In landing the shaft on solid rock, seven boulders 1 to 2 ft. in diameter were encountered. Six of these were under the cutting-edge of the shoe, and were removed only after being broken by chisel and sledge.

While lowering the shaft through the last 5 ft., the upper timbers buckled 18 in. out of line. This necessitated re-timbering from the sand to the surface, an expensive undertaking because the old timbers had to be cut out and replaced in sections.

On completion of the re-timbering, sinking through the shale was commenced. Three shifts were used making a daily advance of 5 ft. The only problem in the shale was the elimination of the water, most of which stopped

STEEL-SHOE METHOD USING JACK-SCREWS.

when the solid rock was reached. This water was taken care of by placing a water-ring at the 85-ft. level with a pump to elevate the water to the surface.

DROP-SHAFT METHOD. The air-shaft was located 350 ft. from the main shaft, and conditions were similar except that the surface at this point was 10 ft. lower, making the distance to be traversed to rock 63 $\frac{1}{2}$ ft. The equipment was the same used at the main shaft. The air-shaft followed a drill-hole tapped by an entry from the main shaft, so that most of the water was drained through this hole and then pumped to surface. The steel shoe was similar to the one in the main shaft, except that it was 10 ft. high instead of 5 ft. The timbering for the first 30 ft. above the shoe consisted of 4 by 6 members laid flat, tied together by $\frac{3}{4}$ -in. lag-screws 10 in. long, spaced 2 ft. apart. The shaft was divided into three equal compartments by 4 by 6 buntons. The middle compartment was left free and was used for hoisting.

An excavation 10 ft. deep was made, the shoe assembled and lined with timbers. Sinking was continued until

*Abstract of paper prepared for the Arizona meeting of the American Institute of Mining Engineers.

the shoe was hung up by the friction on the sides. Then a platform was built every 5 ft. in the end compartments. These 5-ft. chambers were filled with sand to give additional weight, and sinking continued. The ground surrounding the shoe gradually broke in an oval shape. At one place it was necessary to fire a small charge of powder in order to loosen the ground sufficiently at one end of the shaft. As the shoe was sunk, timbers were added at the top of the curbing. This method of building the curb at the top is better than that of adding at the bottom since the timbers are placed more expeditiously.

One difficulty experienced was to keep the bottom of the shoe level. When one side got lower than the other it kicked the opposite side onward. To right it, the lower side was blocked until the higher side caught up. This greatly reduced the trouble.

The progress through the drift material, until the sand was reached, was slower than at the main shaft.

DROP-SHAFT METHOD.

The drop-shaft went faster, however, after reaching the sand. In fact, the difficulty at that time was to keep the bottom of the shaft from moving faster than the top. When within 10 in. of the bottom of the sand, the shaft broke apart 20 ft. from the shoe. This was due to the movement of the shoe being faster than that of the top of the shaft, and to the insufficient strength of the straps connecting the top and bottom of the curb. At this point (20 ft. above the shoe) the curb separated from 6 to 8 in., and the upper part of the shaft kicked over 9 in. A temporary platform of 8 by 8 timber was put in the end compartments and time given for the upper part to settle before starting again. Sinking was then continued and the shoe landed on the solid without further difficulty, aside from hitting two small boulders at the bottom of the sand.

As the excavation was larger than necessary for an air-shaft, it was decided to cement the shaft for a distance of 28 ft. from the bottom of the shoe, in order to stop the water. A wall of cement 4 to 8 in. thick was accordingly constructed. After the cement was given time to set thoroughly, the excavation was again started in the shale and continued without difficulty to the coal. Sinking through the shale in the air-shaft cost slightly

more than in the main shaft because work in the mine prevented careful supervision being given.

One difficulty, encountered in drop-shaft sinking, was in keeping the position of the shaft vertical. At one time this shaft was 2 ft. out of plumb. By regulating the movement at the bottom of the shoe, the shaft partly righted itself, until at the finish in a total depth of 63½ ft. to the shale the bottom of the shaft was 16 in. to the south and 10 in. to the east of the top. Part of this variation was remedied in the cementing.

A much larger amount of sand was removed in sinking the air-shaft by the drop-shaft method than in sinking the main shaft. This could be done without danger of a cavity forming, because the surface dirt followed the air-shaft down. When sinking through the sand was completed, the surface directly surrounding the air-shaft had caved to a depth of 15 to 16 ft. and for a distance of 20 ft. in all directions. In fact, all the shale that was removed through the remaining 92 ft. to the coal did not fill this space at the surface.

A comparison of the two shafts is shown below. The main shaft was sunk 92 ft. by the steel-shoe method, the air-shaft was sunk 82 ft. by the drop-shaft method.

Labor:	Main shaft	Air-shaft
Through drift material	\$917	\$789
Through sand	1,942	542
Through shale	1,065	1,213
	<hr/> \$3,924	<hr/> \$2,544
Superintendence	600	435
Re-timbering	1,343
Cementing	208
	<hr/>	<hr/>
Total labor cost	\$5,867	\$3,187
Materials:		
Curbing	\$1,879	\$1,195
Supplies	900	643
Power, light, water, insurance, etc....	1,249	650
	<hr/>	<hr/>
Total curbing, etc., cost	\$4,027	\$2,487
	<hr/>	<hr/>
Total costs of shafts	\$9,894	\$5,674

CONCLUSION. There was no question of the superiority of the drop-shaft method. It made a net saving of \$4300 in the total cost of the air-shaft compared with the main shaft. A saving of \$2700 was effected in labor, while in the cost of materials, power, etc., the saving was \$1600. A saving in time also ensued, 30 days being required to traverse the sand with the main shaft, while the air-shaft was dropped through in 17 days. The drop-shaft method seems to be the safest, most economical, and most successful that can be adopted for sinking through soft material that lies within 100 ft. of the surface. At greater depths a variation of the method can be used by first sinking a larger shaft close to the soft material, and then telescoping a drop-shaft within it.

SMEETING operations at the Mt. Morgan mine, Queensland, Australia, are improving. One furnace had a continuous campaign of 54 weeks. The matte gravity system is giving satisfaction. It required 52.46 tons of ore to yield 1 ton of blister copper.

Dredging in Montana

By Hennen Jennings

The history and development of gold dredging in this State is described in Bulletin 121 of U. S. Bureau of Mines by Mr. Jennings, who is consulting engineer to the Conrey Placer Mining Co. Mention was made of this company's work by him in an interview published in the PRESS of December 25, 1915. Some of the early dredging appliances used in New Zealand and California are summarized in the introduction, the first dredge having been built on the Clutha river in New Zealand in 1865. The earliest bucket-dredge in the United States was erected near Bannack, Montana. The Alder Gulch and the Ruby districts have produced many millions in gold.

In 1898 the Conrey Placer Mining Co. was formed, to

places: first 16 tables, 85.32%; last 8 tables, 2.6%; tail-slucies, 8.94%; undercurrent, 0.55%; and well, 2.59%. The bullion from the four boats varies from 822 to 873 fine.

Many improvements in dredging have been started in the Ruby district, including the mooring-head or aerial-spud, large buckets, one-piece manganese buckets, manganese baffle-plates in the revolving-screen, 2200-volt motors, and the direct gear-connected motors for the bucket-drive. The technical operations of the Conrey commenced in the earliest days of gold-dredging in this country. The company tested steam against electric dredges, and the sluice-dredge against the stacker type.

Costs in 1915 totaled 5.99c. per yard, there being

SECTIONS OF WASHING-SCREEN, NO. 4 CONREY DREDGE.

exploit a gravel deposit at Ruby, $1\frac{1}{2}$ miles from Alder, and 80 miles from Butte. Since 1899 the company has dug over 37,000,000 cu. yd., yielding 16c. per yard. This represents 80% of the dredging done in Montana. Seven boats were operated, but at present there are four, details of which are given in the table appended.

No. 4 dredge was designed to dig large quantities of ground of low value to a depth of 55 ft. below water-level. Its best record month was in May 1915, when 411,000 cu. yd. was dredged in 82% running time, at a depth of 54 ft., and at a cost of 2.66c. per yard. The buckets hold 16 cu. ft., and weigh 5200 lb. each. The digging motor is of 550 hp., while the total motor rating is 1285 hp. Pumps are of 16 and 14-in. size, and raise 12,000 gal. water per minute. The accompanying sketch shows the washing-screen, which is 50 ft. long and 8 $\frac{3}{4}$ ft. in diameter. It weighs 110 tons, and is probably the heaviest trommel used in gold-dredging. The spuds weigh 44 tons each.

The four dredges cost \$955,000. In all, there are 85 men employed, 36 actually on the boats.

The gold recovered on No. 4 is saved in the following

3,632,677 cu. yd. dredged. Items were as follows: labor, 1.13; fuel, 0.06; power, 1.15; supplies, 0.08; upkeep of chain, 0.98; repairs, 1.65; indirect charges, 0.94; a total of 5.99 cents.

The gravel at Alder Gulch and Ruby is not so hard and compact as that at Oroville and Natoma in California, but is more difficult than that of the Yuba river, though not so deep. Large boulders are found embedded in clay. The bedrock is favorable. The winter temperature of 25 to 30°F. below zero is a great handicap, but this has been successfully overcome. Wages per 8-hr. shifts are higher than in California.

Outside of the Grasshopper and Alder Gulch districts little gold dredging has been done in Montana. Attempts made in other places met with little success. A 5-cu. ft. boat on Cold creek worked part of two seasons in 1905. About 19 miles from Helena the Magpie company operated in 1910. In the same year the Kansas City Commercial Co. started a 7 $\frac{1}{2}$ -ft. boat 10 miles from Iron Mountain; it has run intermittently since. Three other dredges were built by various concerns, but only worked a few weeks.

A New Flotation Oil

As mentioned in the PRESS of August 12, sage-brush will probably supply oil for flotation purposes. For the Arizona meeting of the American Institute of Mining Engineers, Maxwell Adams of Reno prepared a short paper on the subject.

During 1915, a study of the essential oil in desert plants was begun in the chemical laboratory of the University of Nevada. None of the oils so far studied possesses properties of special interest to engineers, except the oil of sage, *Artemisia tridentate*, which has exceptional power as a flotation agent. This plant, known as common sage-brush, also called black sage, is widely distributed over the semi-arid West.

The method of extracting the oil in the experiments was simple. The leaves, twigs, and small branches, are placed in an air-tight drum, having a capacity of 27 cu. ft. Steam is admitted through a number of small openings at the bottom of the retort, and the pressure maintained at 20 to 25 lb. per sq. in. for three hours. The escape of steam from the retort is regulated by allowing it to pass through a stop-cock into a condenser. The water in the receiver is drawn-off from time to time and the oil, which is insoluble and floats upon the water, is thus collected. At the end of two hours most of the oil has been driven out, though traces continue to come over for a much longer time. By raising the pressure, the time required could probably be shortened and the yield increased, but the lack of laboratory equipment prevented the carrying out of this experiment.

The stock-wood, bark, and branches contain no oil, the distribution of oil being limited to the leaves and young shoots. There is a seasonal variation in the amount of oil contained. Samples collected on different dates gave

the following amount of oil: May 1, 0.42%; May 27, 0.6; June 30, 0.72; August 1, 0.9; and September 10, 0.1%. The increase appears fairly constant from early spring, when the leaves first appear, until light frosts occur in the autumn. When the plant is air-dried there is some loss of oil, as the following will show: Two 100-lb. samples were collected at the same time; one was distilled when green, the other was air-dried for 10 days before distillation. The green sample yielded 275 grams, and the dried sample 248 grams of oil, showing a loss of about 10%.

The laboratory can give little data useful in forming an estimate of the commercial cost of production. A man working for six hours, using a pair of common pruning-shears, collected twigs which yielded one pound of oil. Since only a small quantity of the oil is lost if the brush is dried, the most economical method of production would perhaps be to collect it in large quantities, by using a tractor-engine and a drag, in some such way as land is cleared for farming. When the brush is dry, the leaves and young shoots are easily shaken from the limbs. Thus the amount of material to be distilled would be greatly diminished, and the oil obtained at a cost and in sufficient quantity to make it available as a flotation oil, if not alone, possibly as an ingredient, to increase the flotative power of other oils.

The crude oil is dark in color. When re-distilled with steam it is water-white at first, changing gradually to a straw-yellow color on standing. It has the following physical properties. Density at 15 C., 0.9206; refractive index at 20 C., 1.4732; rotation at 20 C., -4.69.

The chemical properties of the oil are as yet undetermined. The important question for the engineer is: Can the oil be produced in quantity and at a cost that will make it available for ore flotation?

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

CUPRO-DESCLOZITE is the vanadate of lead, zinc, and copper. It is a rare mineral found at Camp Signal in San Bernardino county, California.

A TON of Atlantic Ocean water, evaporated, yields 81 lb. of salt; while equal quantities from the Pacific Ocean and Great Salt Lake, Utah, gives 79 and 175 lb., respectively.

THE LATENT HEAT of fusion of gold is 163 calories. In the case of most metals the latent heat of fusion is about one-third the heat required to raise the metal from absolute zero, -273°C ., to its melting-point.

GOLD in ore of south-eastern Alaska, principally in the Juneau district, averaged \$1.79 per ton in 1915, and silver 1.5 cents, against \$2.43 and 0.8 cents in 1914, respectively. Nearly 3,000,000 tons was treated.

BURNING POWDERED COAL is the best method by which to obtain perfect combination of the air and coal, and by which the highest degree of perfection in combustion may be obtained. The greatest precision is required in its control in order to produce satisfactory results.

GLASSWARE for chemical purposes, equal to the famous Jena, Germany, product, is now being made in the United States, according to Allen Rogers, of the American Chemical Society. The domestic glass is to be exhibited at the Second National Exposition of Chemical Industries at New York on September 25. Many other American products will be on view, also moving pictures showing certain industries.

FIRES have been common in the United Verde copper mine for 22 years. The soft and highly pyritic (mostly chalcopyrite) nature of the ore is responsible for most of these outbreaks. The Plenum system of fighting the fires has been successful since 1905. Briefly, this consists of forcing air under pressure, 2 to 5 lb. per sq. in., into the fire area. The air pressure varies with the gas pressure, and must be sufficient to keep back the gas and to cool the ground, so that work can be done.

COPPER RELICS of a pre-historic age have been discovered in a mine of the Cottonwood district near Salt Lake City. Besides copper, iron, and flint tools, a marble tablet decorated with crude drawings and hieroglyphics apparently of Indian origin has been found. Native copper ore exists in the rocks near-by, suggesting the source of the copper in the tools. The exact location has been kept secret. Many interpretations have been devised to account for the drawings and hieroglyphics on the marble tablet; one story concerns a black-eyed Indian

princess called No-ni-shee, 'the maid who put the salt in Great Salt Lake' by her weeping. As is well known, the Emma, an old copper mine in the Cottonwoods is being re-opened, and not far away are the great copper mines of Bingham Canyon.

NOT MORE THAN 30% of the timber in the forests of the United States is ever utilized as lumber, according to figures recently compiled by the office of Industrial Investigations of the Forest Service. Seventy per cent, chiefly in tops, limbs, stumps, bark, saw-dust, slabs, and small and defective trees, is for the most part wasted. Of the wood in the individual tree, 33.5% is made into lumber, and of the logs that reach the mill 40.3% is worked up into lumber. How this waste occurs is well illustrated in the saw-kerr or saw-dust, which averages 13% of the log. This means that for every seven one-inch boards sawed from a log, one board is wasted in saw-dust.

GUN-COTTON was discovered by Schonbein at nearly the same period that nitro-glycerine was discovered by Sobrero. Trials were made in 1846 by the French war department to utilize gun-cotton, but though chemists like Pelouze worked for years, an unfavorable report was made, as too many spontaneous explosions ensued. Later in Austria, a careful investigation after improvements by Baron von Lenk indicated the practicability of using gun-cotton for fire-arms as well as blasting. Schonbein's discovery indicated that when cotton-wool is steeped in a mixture of strong sulphuric and nitric acids, a transformation into gun-cotton takes place almost without change in appearance. Gun-cotton is not so powerful nor so cheap as nitro-glycerine and is therefore not so much used in mining, but has the advantage of not freezing. Blasting gelatine, an important modern explosive, is made by dissolving gun-cotton in nitro-glycerine.

DYNAMITE of the variety known as 'straight dynamite' and of the strength known as 40% contains 40% of nitro-glycerine, 44% of sodium nitrate (which is the principal ingredient of black powder), 15% of wood pulp, and 1% of calcium or magnesium carbonate. A typical 60% dynamite contains 60% nitro-glycerine, 23% of sodium nitrate, 16% of wood pulp, and 1% of calcium or magnesium carbonate. Low-freezing dynamite or the ammonia dynamites are not so powerful in action as straight dynamite. A low-freezing dynamite of 50% strength contains only 38% of nitro-glycerine, the other 12% being a nitro-substitution compound. Ammonia dynamite absorbs water readily, which is a disadvantage. A 50% ammonia dynamite contains only 27% of nitro-glycerine, with 25% of ammonium nitrate, and 36% of sodium nitrate. A gelatine dynamite of 50% strength contains 42% of nitro-glycerine, 1.5% of nitro-cellulose, and 45% of sodium nitrate. The gelatine formed by the addition of nitro-cellulose to nitro-glycerine is impervious to water, and this explosive is adapted for wet blasting.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

ANOTHER DRAINAGE SCHEME.—ANOTHER DREDGE TO BE BUILT.—

ALLEGHENY, PROGRESSIVE, AND GARBUTT IMPROVEMENTS.

Drainage of the entire Leadville district to a considerable depth is now practically assured. The Down Town section has been unwatered through the Penrose shaft to a depth of 978 ft.; Fryer hill and the Big Evans basin have been drained through the Harvard shaft to a depth of 800 ft., and sinking of the shaft is about to be started; the Mikado shaft on Iron hill is being prepared for unwatering that immense area to a depth of 1100 ft.; and another large unwatering enterprise has been launched for draining part of California gulch and Rock hill through the La Plata.

Still another drainage project is being perfected to operate through the Wolfstone shaft, where the Empire Zinc Co. and Western Mining Co. recently completed unwatering to the 1000-ft. level, and through the Greenback shaft adjoining. Layne-Bowler electrical deep-well pumps have been installed in both properties under the direction of W. E. Jones of Los Angeles. The pumps in both shafts will be lowered together early in the week, and pumping will be continued until the water-level has been forced below the Wolfstone shaft-bottom, at a depth of 1320 ft. The sinking-pumps will be connected with large station-plants of steam machinery that are installed at 1000 ft. in the Wolfstone and at 900 ft. in the Greenback. These relief pumps will throw the water to the surface. The two plants will pump 2500 gal. per minute. The Wolfstone-Greenback scheme is regarded as being the most important pumping project that has yet been undertaken in the district, because it will open to mining a more extensive area of rich territory and at greater depth than any previous unwatering has done. Together with the Mikado, which is expected to be pumping within the next three months, the Greenback and Wolfstone will form the strongest combination in the district. When these enterprises are completed, the district will be drained from Rock hill on the south to Prospect mountain on the north, and from the Down Town section on the west to Adelaide park on the east, a territory about 16 miles square.

The second dredging company to enter the Leadville district is now being formed by John R. Champion, former superintendent of the Yak Mining, Milling & Tunnel Co., who has secured control of a large tract of placer ground in the mouth of Iowa gulch. For several weeks he has been prospecting this area with shafts from 10 to 15 ft. deep, yielding from 45c. to \$1.50 per cu. yd. so far. These results are regarded as ample justification for the installation of a dredge. At present the water problem is delaying progress, as it will be difficult to secure enough to float the boat, especially when it begins to advance up the gulch. This obstacle will, however, be overcome as the gold-content is too high to be discarded. Operations may not be undertaken until next spring, but not later.

A long term lease has been secured by W. E. Bowden on the Allegheny mine on Yankee hill, in the centre of one of the richest, and at present, most active sections of the district. The property is surrounded by the Mikado, Robert Emmet, McCormick, and El Paso, and directly in line with the great ore-shoots that have been developed through these and other nearby properties. At present work at the Allegheny is confined to re-timbering the shaft, which is 700 ft.

deep. A steam plant has been installed at the shaft, but as soon as the re-timbering is finished, a modern electric plant will be put in. The sinking of the shaft several hundred feet will follow, as it is proposed to cut the Ponsardin ore-shoot, which dips under the Allegheny to the north-east.

In charge of Warren F. Page, the old Progressive mine on Fryer hill has been re-opened and the shaft is being re-timbered. A new electric surface plant has been installed, and work is being done as rapidly as possible. The Progressive was one of the bonanzas of the early days, when Fryer hill was the scene of the greatest excitement in the history of the district. At that time the mine was a consistent producer of high-grade silver ore. Ten years ago it was operated by lessees, who also extracted some similar grade ore, but the closing of other mines adjoining, which were then pumping,

GREENBACK SHAFT AT LEFT, WOLFSTONE AT RIGHT; NEW DRAINAGE SCHEME AT LEADVILLE.

drowned the high-grade stopes. Since then no work has been done, and undoubtedly it would still be idle but for the draining of Fryer hill through the Harvard shaft, an undertaking just completed by the United States Smelting, Refining & Exploration Company. An extensive campaign of development has been planned by Mr. Page for the re-opening of the rich stopes supposed to be uncovered in the bottom levels.

The manager of the Garbutt mine, John Cortellini, is now completing plans for the construction of a 250-ton mill for concentrating the gold-bearing ore that is being extracted from the Garbutt and Ilex No. 3 shaft adjoining, and which is under lease to Cortellini and his partners. The orebody, which is an immense porphyry cap, is the largest now open in the district. The daily output is 250 tons, and it is stated that the ore will average \$20 per ton. Production is now shipped directly to smelters, and is subjected to a heavy treatment charge that would be saved if the ore were concentrated before shipping. It is estimated that the plant proposed for the Garbutt will cost between \$60,000 and \$70,000. At the present rate of production, this amount would be realized on reduced costs in one month. A small but continuous fissure of rich gold-copper ore has been opened recently in the Garbutt, and is now being developed through 10 levels. The vein averages 3 ft. in width, from which 50 tons per day is being extracted.

BUTTE, MONTANA

BUTTE & BACORN AFFAIRS.—SLAG TREATMENT.

The re-organization of the Butte & Bacorn has put the property under the control of the newly formed Great Butte Copper Co. The failure of the Butte & Bacorn's fiscal agents in 1907 left the company \$14,000 in debt. This, with the cost of maintaining the property, of perfecting title to unpatented claims, of taxes and litigation, has resulted in a debt of \$50,000 and interest. The indebtedness is secured by a mortgage that has been overdue since 1912. Foreclosure proceedings were commenced some time ago, and a re-organization of the company would have been effected through the courts if the shareholders had not been successful in their efforts to re-organize it. The new company has a capital of \$1,000,000. The shares have a par value of \$1; 200,000 of them are in the treasury. All of the property of the Butte & Bacorn was sold to the new company for 400,000 shares, or one-half of the stock which is to be issued. This gave holders one share of new stock for each 10 shares of Butte & Bacorn stock. The remaining 400,000 shares were sold at 66c. per share, and the fund so realized amounts to \$264,000. The plan had the same effect as though each holder had given up half of his stock to be sold for the benefit of the enterprise. Out of this fund the old company's debts will be paid. The Calumet shaft has been bought back for \$19,000. It was sunk to a depth of 1000 ft. just outside of the company's line, but on ground which was held under option at that time. For this \$19,000 the company will get only the shaft and such surface as is necessary, but it will hold an option on the mineral rights of the three adjoining claims on the same terms that the Butte & Bacorn had in 1907. The company will have \$180,000 available for continuing development. The shaft will be pumped out and repaired, and some driving and cross-cutting done on the 1000-ft. level. Sinking of the shaft to the 1500-ft. level will be started, and the company has enough money to drive 5000 ft. of drifts and cross-cuts at that depth. Several large veins outcrop on the company's ground, and good copper ore has been shipped from one of them. The property is one mile north of the Butte & Superior. It is presumed that the veins have been leached of most of their mineral content from the surface to the 700-ft. level; below that level either copper or zinc may be found. The copper-bearing veins of the Butte district contain iron oxide at the surface, while the outcrops of the silver-zinc veins consist mainly of quartz, stained with manganese oxide. The surface conditions indicate that the veins will be copper bearing at depth, and as the management is capable and efficient the Great Butte Copper Co.'s chances of becoming a copper producer are considered good.

The high price of copper makes it possible to ship some of the slag dumps accumulated at the old smelters near Butte. The slag that contains the most metal is usually in the lower parts of the dumps. This is the slag that was made when the smelters were first blown-in, and after covered to a depth of 20 ft. with slag that is too low in copper to be profitably worked. The lower stratum is being mined and the overburden held in place by timbering. The tailing dumps from the old concentrators have been worked for years. The acid mine-water is used to leach them and the copper precipitated on scrap iron. In some cases tailing was covered with slag, and in places where the slag is not too deep it is being removed and the tailing that seems to be worth more than the average is shipped to a smelter. The slag is useful as an ingredient in concrete, and about 100 tons per day is used for that purpose. Granulated slag from the Anaconda smelter has been tried as ballast, but it does not pack well and is not generally considered satisfactory for that purpose.

Two electric motors, a tube-mill, beister tables, and other machinery have arrived at the Ophir mill for the Butte-Detroit company. A flotation plant may be erected to treat the zinc-silver ore. The shaft is completed to 980 feet.

JOHANNESBURG, TRANSVAAL

CINDERELLA CONSOLIDATED AFFAIRS.—FAR EAST RAND.—SUNDAY WORK AT THE MINES.

The optimism of the mining financier is an asset to the Rand. The chairman of the Cinderella Consolidated assures the shareholders that fresh funds to re-start the mine will be found, and there is little doubt he will manage it. Already £1,250,000 has been spent on the mine. The net result being that after a lengthy but hand-to-mouth existence as a producer, the mine was closed-down, because it failed to pay operating costs, let alone debenture interest and redemption. However, George Denny has made a report on the mine, and shareholders—poor beggars—have been regaled with crumbs from the rich man's table, the said crumbs being assorted fragments from what is believed to be a very bulky document. According to the chairman, Mr. Denny reports most favorably on the future prospects of the mine. The reasons given for the former failure being:

(1) Insufficient working capital to develop the mine properly.

(2) Mistakes in mining, the management leaving the most profitable portion of the orebody in the foot or hanging wall, I forget which.

Mr. Denny may be quite right and bad mining may be the real reason for the mine not paying. Have the shareholders any right to grumble at the past management? Certainly not says the cheerful chairman; he assures them that the mine was most capably and carefully managed, but it required a special genius to find the hidden treasure. This having now been found all will be well. After reading Mr. Denny's report, according to the cheerful chairman, mining on the Cinderella Con. will be made quite easy and under the same three Cs management as in the past the right and not the wrong orebody will now be worked.

A lot yet remains to be done on some of the mines, especially the 'deep-levels' of the Far East Rand, to make them reasonably healthy. A man I know well was out of a billet and secured a shift-boss's job on one of the most highly boomed and advertised mines in that district. The pay was £40 per month, free house, water, lights, coal, etc. He stayed just three days and left of his own accord, saying that he would not stay if they gave him £60 and fed him. Smoke and dust simply awful, phthisis in six months, is his verdict, and he is by no means a particular person, and is an old hand at mining. He is now working for less money on an outcrop mine, where proper attention is paid to health. On the deeper 'deeps' this sort of thing seems common.

I am sending you a copy of the State Mining Engineer's report on the Far East Rand. The Government has not yet accepted any tenders, and report says that the American syndicate did little or no business. A great many amiable people are insisting that all the wonderful millions guessed at by the Government engineer must be kept in the country and none of it wasted in paying dividends to overseas shareholders. The only way, according to these enthusiasts, is for the Government to develop and mine the areas, and keep all the profits for the good of South Africa. It is a great pity that the Government is frightened to take a bold line and let the leases to responsible people and get the work going. Of course, they, the members of the Government, are suffering from a failing common to some of their ancestors "of asking too much and giving too little," and they are a bit spoiled by the wonderful terms they got for leasing the Modder areas. But the personal element entered very largely into the last deal. Everybody supposed to be interested had been consulted and it was arranged that the Mines Selection Company should be the only tenderer, but the Corner House and their associates had forgotten to consult Barnato Bros., who at the last moment put in a more favorable offer, and obtained the lease. This sort of thing is not likely to be repeated. The

least speculative areas are probably Brakpan 16 and Springs 15 and the bit of Geduld adjoining the Geduld mines and Springs 15. Outside of this area the ground is very speculative, and it is absurd of the Government to hang up the exploration and development of the district by being so greedy. It would be a great deal more to the advantage of South Africa if they gave fairly generous terms to the enterprising firms that having done well in the past are prepared again to take chances, but in return for really good terms it should be a *sine qua non* that every possible precaution should be insisted to lessen the dust and smoke which in most of the 'deeps' is a crying scandal.

Your correspondent's remarks on Sunday labor in your number of June 24 seemed like very ancient history to us over here, the ridiculous idea that mining should be kept going every day of the week has long ago been abandoned, and it seemed funny to read that such ideas should persist on your side. For our local conditions, however, we have not to thank any particular virtue of our own or any excess of brain-power, but simply that long ago the Government made strict regulations, and any manager who broke them would soon lose his ticket and his job. The only way Mr. Brown will get the matter reformed is, I think, by the strong hand of the law, although I admire his faith in human nature in thinking it possible without compulsion to knock sense into shareholders and directors. Experience has taught us here that eight hours underground and no Sunday work, also compulsory holidays away from the mines, are really aids to economic working, but we should never have had a chance to learn this if the law had not compelled us to do so.

PLATTEVILLE, WISCONSIN

SITUATION IN THE ZINC REGION DURING AUGUST.

During August operating companies struggled against lower offerings for zinc ore and high costs of supplies and labor, but maintained working schedules without interruption at all points in the field, production and shipments comparing favorably with periods of higher prices.

The month opened with 60% zinc concentrate and premium grades on a basis of \$60 per ton. This price was shaded to \$50 per ton on second and medium-grade ore. Products assaying 40 to 50% zinc-content, offered by independent companies, were in fair demand part of the month, and some found its way into the bins of the zinc-ore refineries offering a market. Most of the ore that tended to help continue nearly normal production came from the groups of mines operating in combination with zinc-ore refineries or the smelter companies. A careful estimate of surplus on August 26 showed over 5000 tons. This is held entirely by small independents who can ill afford under present conditions to hold such a dead investment. No talk of a shut-down has been heard anywhere in the field, and new companies just completing and equipping mines are going ahead undismayed at the rather discouraging conditions that confront them. Leading mine managers declared that it is less profitable mining and selling ore on present offerings than it was two years ago, when jack sold at \$10 per ton, 60% basis. Prices for mining supplies have increased from 30 to 40%, and labor is high, machine-men being paid from \$3.50 to \$4 per shift; miners \$3; mill-men, \$25 per week; muckers, 16c. per ton; trammers, \$2.75 per shift; engineers, \$100 to \$125 per month; underground bosses, \$100 per month; and cartage 25c. per ton-mile. At the same time the managers consider that it is impossible to lower wages, as men of all classes are in great demand throughout the region. It is predicted that a change for the better must come soon, otherwise many zinc mines will be compelled to suspend operations. There does not appear any combination of circumstances that invite a change, and while the field is making the best showing in its history, there is a feeling of suppressed discouragement. Many concerns that have earned enviable

reputations as dividend-payers with lower markets have declared no distribution of profits for several months.

The marketing of pyrite was nominal. Production is bound to continue without abatement, as this is impossible in the Wisconsin field, where nearly all of this is secured as by-product at the zinc-ore refineries. Such sales as were made came from one or two refineries that have been discreet enough to secure contract arrangements. One of the largest refineries here submitted a statement near the end of the month that there is held in the field at all plants more than 15,000 tons of iron pyrite, all fine secured from separation of zinc ore.

Shippers of carbonate of zinc ore experienced another dull month, prices apparently being good but the demand indifferent. The Hard Fibre Co. of Delaware entered as a new buyer. Deliveries of ore during August, up to and including the 26th, were as follows:

Districts	Zinc pounds	Lead pounds	Pyrite pounds
Benton	18,662,000	564,600	90,000
Galena	5,808,000
Milfin	4,144,000
Cuba	3,928,000	60,000	2,169,600
Linden	3,504,000	77,970	160,000
Hazel Green	2,940,000
Shullsburg	2,352,000	30,000
Platteville	2,216,000
Highland	850,000
Montfort	342,000
Mineral Point	228,000	728,000
Potosi	70,000
Total	45,054,000	732,570	3,138,600

The gross yield of crude ore from all mines for the field exceeded 17,500 tons; several mines that had accumulated large stocks of concentrate unloaded this surplus, which at the beginning of the month stood at nearly 10,000 tons. Net deliveries out of the field, nearly all high-grade refinery product, totaled 9500 tons.

SUTTER CREEK, CALIFORNIA

CENTRAL EUREKA MINE.—ARGONAUT MILL.

Delay in the arrival of power drills is given as the reason for deferring the proposed sinking of the Central Eureka shaft. The sump has been cleaned-out, and the shaft-timbers put in good shape for sinking for one or more new levels below 200 ft. The orebody now yielding good ore on the present lowest level gives indication of persistence, and a comparatively short cross-cut from the shaft should reach this ore after the shaft is deepened. Twenty stamps of the Central Eureka 40 are in operation. V. S. Walsh of San Francisco, the president of the company, has been in Sutter Creek during the week, conferring with superintendent Fred Jost.

It is now expected that the beginning of the year will see crushing started at the new Argonaut mill at Jackson. The batteries are now being erected, the idea being to complete the installation of the extra 20 stamps with which this mill is to be equipped, before beginning the removal of the present 40 to their new place, and by moving 20 at a time, there need be no cessation in the operation of at least 40 stamps while the change is being made, a portion of the ore going to supply batteries at each mill while the change is in progress. Cars on a steep inclined track will be used to convey the ore from the bins at the shaft to those at the new mill 800 ft. west, and this will be so arranged that one employee stationed near the shaft can regulate the cars going to the mill and returning, as well as the division of ore for the different batteries. A number of improvements will be incorporated in this mill. Flooring has yet to be laid and concentrating machinery has not yet been installed, it being deemed expedient to do this after everything else is complete.

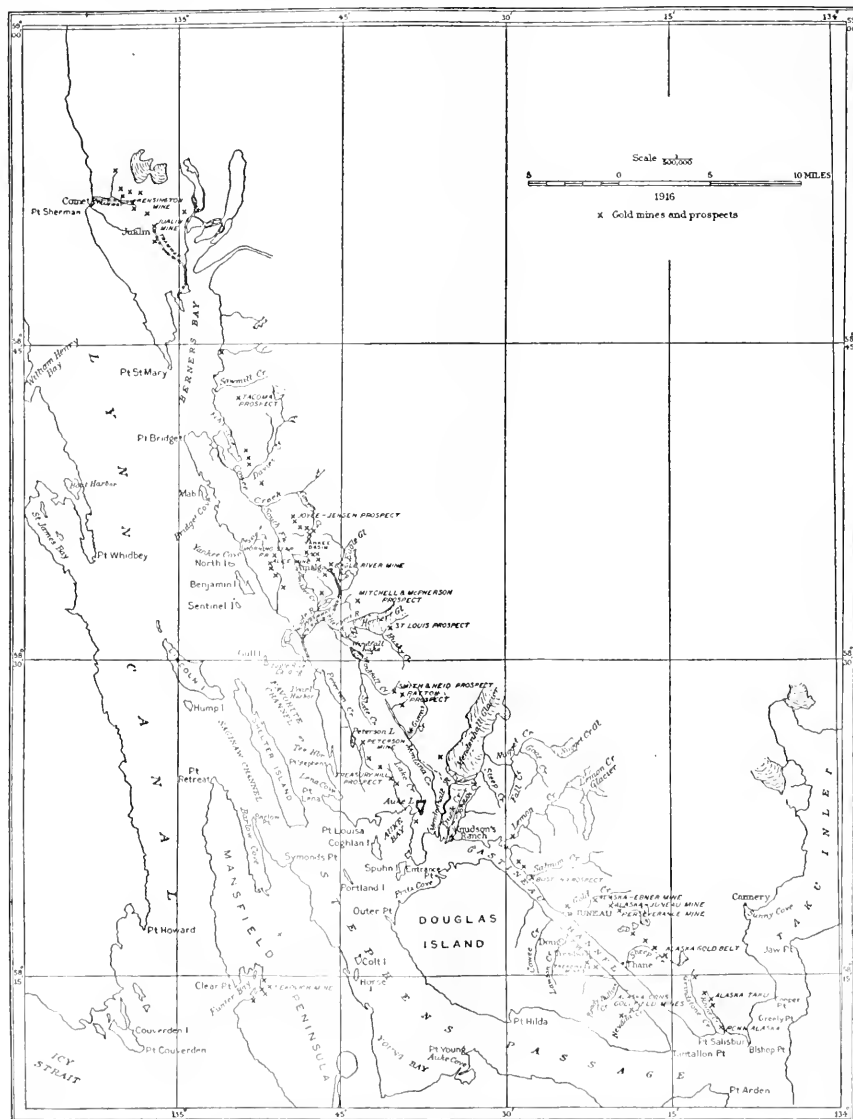

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Mining developments and water-power investigations in south-eastern Alaska are described in Bulletin 642-B of the U. S. Geological Survey by Theodore Chapin and George H.

Canfield. Some useful maps are included. Progress at the gold and copper mines of the Juneau, Wrangell, Ketchikan, Prince of Wales, and other islands is detailed. The value of the mineral output in 1915 was \$5,435,586 of gold, \$302,431 of copper, and \$352,554 of silver, marble, lead, and other. The

MAP OF THE NORTHERN PART OF THE JUNEAU GOLD BELT.

Juneau district produced most of the gold, which amounted to \$5,353,255 from 2,989,730 tons of ore, compared with \$4,157,191 from 1,712,530 tons in 1914. The Kasaan peninsula was the centre of copper mining in the south-east. From 50,406 tons of ore the yield was 1,728,182 lb. of copper, also \$33,000 of gold and silver. The streams of the Territory are important factors in its growth.

In Bulletin 642 of the U. S. Geological Survey is a report on progress of investigations during 1915 into the mineral resources of the Territory, by Alfred H. Brooks and others. As we have abstracted freely from advance chapters there is no need to give this useful publication further mention.

JUNEAU. During the first 10 days of September the Alaska Gold Mines reports that the average grade was \$1.51 per ton, an increase of 9c. per ton over August. There was treated in the period 50,150 tons, equal to 5000 tons daily, also an increase.

ARIZONA

BISBEE. On the 20th the American Institute of Mining Engineers met at Bisbee. E. C. Harder discussed the manganese situation. He said that the situation in the United States at the present time regarding the supply of manganese ores and alloys of manganese is one of great seriousness, and is likely to become increasingly so while the War continues. The dependence of America on foreign countries for this supply is being forcibly indicated. Other papers dealt with the exhaustion of oil and gas in the United States, geology of the Warren district, co-operative effort in mining, and gold and silver deposits in North and South America.

DOUGLAS. The first of the technical sessions of the convention of the American Institute of Mining Engineers, which is meeting in Arizona this week, were held on September 19 on the general subjects of smelting and leaching. Before the opening of these sessions the several hundred attending members, who are traveling through the State by special train, visited the reduction works of the Copper Queen Consolidated and of Calumet & Arizona Co. A. G. McGregor, of Warren, in an address on the 'New Copper Smelting Plants in Arizona,' told the engineers that in Arizona during the past five years there has been more activity in copper-smelting plant construction than in the same length of time in the history of the world. Mr. McGregor said that in this period five new copper-smelters had been constructed and put in operation. The monthly output from these plants, he said, averages from 5,000,000 to 18,000,000 lb. He then described new problems that had been met successfully and new features in plant design and equipment which had been developed. At the evening session on leaching, Frederick Laist and Harold W. Aldrich described the 2000-ton leaching plant at Anaconda, Montana. A paper on 'Possibilities in the Wet Treatment of Copper Concentrates' was read by Lawrence Addicks, and 'Leaching Tests at New Cornelia' were discussed by H. W. Morse and H. A. Tobbelmann. In the course of the day's proceedings John C. Greenway welcomed the members to Arizona and L. D. Ricketts, president of the Institute, responded for the delegates. The party left for Bisbee where the next day's sessions were held. Mining and geology were the subjects to be taken up in the technical discussions.

GLOBE. On the 21st the American Institute of Mining Engineers met at Globe and mainly discussed flotation. The Old Dominion mine and works were inspected.

(Special Correspondence.)—The Gold Dust mill has started on custom ore, treating that from the Gold Dust, Gold Key, Big Jim, and Lexington mines. For a month the work will be largely experimental, trying the process of superintendent Brush. A centrifugal separator, using mercury, is part of the apparatus. The ore is reduced to *minus* 100-mesh before going to this machine.

The Big Jim mine has been the subject of rumors, and an

attempted bear raid on shares. The mine was then examined, resulting in shares rising to over \$1. Work continues at 500 ft. The general average of the mine ore is claimed to be \$20 per ton.

The Tom Reed output is now at the rate of \$125,000 per month.

Oatman, September 11.

ARKANSAS

YELLVILLE. According to J. H. Hand, August shipments of zinc ore amounted to 79 carloads. Stocks are estimated at 1500 tons. The Rush district supplied 34 cars.

CALIFORNIA

The wage situation along the Mother Lode is as follows:

On September 14 the following letter was sent to employees by Grass Valley companies:

"We have learned that some of our employees believe that they are entitled to larger compensation and are circulating a petition for higher wages, stating therein among other things, that they are not in favor of strikes, etc., but believe in presenting their matters to their employer by petition. While it is true that wages of copper miners have been increased on account of the high prices of copper, the same conditions do not prevail in gold mines where the production brings the same price and where the cost of supplies has increased. We will, however, commencing October 1, 1916, pay the miners \$3.25, and shovelers and car-men \$2.75 per day. The bonus system will be continued as heretofore until further notice. We thank you for your co-operation and goodwill of the past, which we hope will continue.

EMPIRE MINES	BRUNSWICK MINES
NORTH STAR MINES	SULTANA MINES
GOLDEN CENTER MINES	UNION HILL MINES
ALLISON RANCH MINES	POLAR STAR Mfg. Co."

The 1000 men employed in this district will receive about \$50,000 extra yearly. The increase is 25c. per day.

On September 15 the following letter was mailed from Jackson to mine operators and owners in Amador county:

"Pursuant to action taken by Local No. 135, Mine, Mill and Smelter-workers Union, of United Federation of Miners, we invite you to meet with this Union to discuss the matter of establishing a uniform wage scale for Amador county. The Union will meet you individually or collectively, preferring the latter. If any Operator or Owner does not communicate with us respecting this matter before Monday, September 18, 1916, it will be taken for granted that such operators or owners refuse to meet with us. Trusting this meeting will be agreed upon and a friendly understanding had, we remain most respectfully, Local No. 135, Mother Lode Mine, Mill and Smelter-workers' Union.

By JAMES GAMBIRG no. secretary."

An answer was requested by Monday, the 18th. The Keystone, Little Amador, and Old Eureka companies, which are paying 25c. daily more than the others are not included. The wage paid by the former is \$3.50 for miners and \$3 for car-men and muckers.

On the 15th representatives from nearly all mines in Amador county conferred on the question at Jackson.

(Telegraphic Correspondence.) Strike on today; every mine in Amador county is idle, except for pumping.

Sutter Creek, September 19.

The State Industrial Accident Commission reports that during 1915 there were 533 fatalities; 1264 permanent injuries, and 65,741 minor accidents in all industries. Total payments amounted to \$2,002,706, up to June 30, 1916, divided into compensation \$1,150,504, and medical payments \$852,203. There were 13,254 injuries out of the 67,538 that lasted 15 days and over. The death list is a decrease of 158 compared with the previous year.

ANGELS. Local and San Francisco men have organized the

Angels Deep Mining Co. to develop the Pioneer mine, near the Gold Cliff and Lindsay mines. The shaft is 100 ft. deep, and equipment is sufficient for 500 ft. J. C. Benson is in charge.

FORBESTOWN. Ore treatment problems seem to have been solved here by extensive tests made with flotation systems, according to M. J. Cooney.

GRASS VALLEY. The Union Hill Mining Co. held a meeting at San Francisco last week. F. W. McNear is president. H. E. Fluke of Pasadena, one of the largest shareholders, was re-elected a director. W. H. Hamilton was elected to the directorate in place of G. S. Johnson. E. L. Oliver is treasurer, and Errol MacBoyle general manager. Sufficient tungsten ore was extracted to pay operating charges, and there is 10 tons of it on hand. The main shaft is to be sunk 400 ft. deeper, and electric pumps are contemplated to reduce costs.

The Empire Mines Co. is surveying an electric tramway one mile in length to connect its Empire and Pennsylvania mines. A 35-lb. rail is to be used, also a 4-ton electric loco capable of hauling 30 tons of ore. The present 60-stamp mill and cyanide plant is to be increased to 100 head and extra treatment capacity. The two mines are to be connected, necessitating sinking the Pennsylvania from 2600 ft. to 4600 ft. The present output is 415 tons of ore daily.

PLYMOUTH. The Plymouth Consolidated reports as follows for August:

Ore milled, tons	10,600
Total value	\$57,585
Working expenses	25,280
Development charges	9,838
Surplus	22,467
Other expenditure	7,319

SAN BERNARDINO. A decision in the lawsuit over the Searles Lake potash deposit in San Bernardino county was given by the Superior Court of this county on September 14. The decision is in favor of the defendants, the American Trona Corporation and others, in an action to quiet title brought by R. Waymire and E. Thompson, respectively, the claim-jumpers. It is unlikely that there will be an appeal.

COLORADO

CRIPPLE CREEK. An examination of the Cresson mine by Louis S. Noble shows reserves on August 1 to be 201,388 tons of ore averaging \$31.10 per ton. The net profit in this is estimated at \$4,130,318, or \$20.51 per ton. August shipments were at the rate of 6300 tons per month. The 1203 stope yielded \$33.33 per ton.

During August there was 11,000 tons of \$5 ore moved from the old Economic dump on Squaw mountain. The Economic Dump Leasing Co. controls the material.

Lessees of the United Gold company shipped a total of 1700 tons of \$20 ore to the Golden Cycle mill in August. The mines are the Trail, Trachyte, W. P. H., Damon, and Viola.

LAKE CITY. To treat old stope-filling and ore dumps the Colorado Utah Mines Operating Co., owned by Salt Lake City people, is to install fine-grinding machinery. The present mill is treating 40 tons daily. The treatment includes table concentration and flotation, yielding copper-lead-silver-gold concentrate. G. E. Edwards is manager.

RICO. The Rico Wellington company is out of debt and has \$6000 cash on hand, also 27 cars of 4 to 16% copper ore in transit to smelters. Profits in future should be from \$15,000 to \$20,000 monthly.

SILVERTON. August was a record month for shipments, the total being 1196 tons of crude ore and 5830 tons of concentrate.

IDAHO

HAILEY. Early in October the new 300-ton mill at the North Star-Triumph, operated by the Federal Mining & Smelting Co., will be ready for work. The mine is opening well.

MILLAN. In an extension of No. 6 tunnel of the Morning

mine the Federal company has opened a new orebody, 20 ft. wide, carrying high zinc-content as a sulphide. This shoot was unexpected.

MURRAY. The O.-W. R. & N. Co. has awarded a contract for construction of its new Beaver Creek branch to Twoby Brothers, railway construction contractors of Spokane and Portland, Oregon, according to announcement made in Spokane by Robert Twoby. Work will begin as soon as crews can be recruited and machinery assembled. The contract price is said to be approximately \$200,000, and it is probable that the 10-mile line will be completed and ready to operate in the next six months. The new road will connect with the Murray branch of the O.-W. R. & N. at Idora spur, and will provide transportation facilities for the Consolidated Interstate-Callahan, Ray-Jefferson, Idora, Tuscumbia, Virginia, Sunset, Toughnut, Friend, and several other properties in the district.

PINE CREEK DISTRICT. In the Denver mine adit the ore-shoot has been opened for 140 ft. The last sample across 54 in. assayed 31% lead, 20% zinc, and 19 oz. silver per ton. A compressor is being installed. W. A. Beaudry is in charge.

KANSAS

PITTSBURG. There are over 600 smelter-men out of work in this centre. The American, Bruce, and Lanyon smelters are closed, while six of the eight furnaces of the Pittsburg company are down. The Joplin Ore and the new smelter at Weir are the only ones in full operation, and the former is also to suspend work.

MICHIGAN

Houghton. Ore shipped to mills during August was as under, in tons:

Franklin	23,400	Tamarack	33,525
Centennial	13,100	Mohawk	54,000
Allouez	41,100	Wolverine	28,500
Mass	32,700	Abmeek	106,300
Superior	16,900	Oseola	119,250
Hancock	18,500	Calumet & Hecla	275,600
LaSalle	10,900	Copper Range	111,300
		Isle Royale	77,700

These figures represent a normal output for most of the mines. Centennial is extracting more than usual. Allouez should make an increase in September. During the first half of the year White Pine has treated 600 tons of ore daily, its mill capacity being 800 to 1000 tons.

MISSOURI

JOPLIN. Last week there was a noticeable falling-off in zinc and lead concentrate sales. The 'turn-in' was 3238 tons of blende, 70 tons of calamine, and 862 tons of lead, averaging \$51, \$40, and \$65 per ton, respectively. The total value was \$235,059, and for 30 weeks, \$23,881,158.

At the D. C. & E. mine, near Webb City, a Layne & Bowler vertical centrifugal pump, an innovation for this region, is to be installed. Its capacity is 1700 gal. per minute.

MONTANA

In Bulletin 121 of the U. S. Bureau of Mines, the history and development of gold dredging in Montana is discussed by Hennen Jennings. A chapter on placer-mining methods and operating costs, by Charles Janin, is included. These were papers read at the second Pan-American Scientific Congress held at Washington, D. C., December 27, 1915, to January 8, 1916. The publication covers 63 pages, and has 30 illustrations. Montana is next to California in amount of gold recovered by dredging. The first successful bucket-lift dredge in the United States was erected on Grasshopper creek, Beaverhead county, Montana, near Bannack. Work done in Alder gulch and the Ruby district, in Madison county, is described, especially that of the Conrey Placer Mining Co. at the latter centre. Its first

operations were in 1899, since then 37,000,000 cu. yd. of gravel, yielding 16c. per yard, has been dug. This is 80% of the total yardage dredged in the State. Four boats are now at work. These are electrically driven. They handle 96,270, 82,709, 82,415, and 300,000 cu. yd. each, respectively, per

2117 ft. at a cost of \$4.97 per foot. In the Combination mine the north and south drifts at 180 ft. depth yielded 52 tons of \$24.39 and 144 tons of \$26.25 ore, respectively. On the 333-ft. level of the Laguna-Red Top, sill 10610 produced 82 tons assaying \$10.34 gold and 2.46% copper.

GOODSPRINGS. On September 15 the Yellow Pine company distributed 10c. per share, equal to \$100,000. This makes \$700,000 for the current year.

MANHATTAN. Development in the White Caps mine continues to be satisfactory, especially at 300 ft. A new vein in limestone, parallel to and 20 ft. from another, is 14 ft. wide, assaying \$21 per ton. It is more oxidized than any other ore at this depth. A 10-drill compressor is to replace the present one of 4-drill capacity. Milling machinery has been ordered.

Dexter lessees are sending ore to the War Eagle mill. Wittenberg & Mushett have resumed work at the Big Pine mine and mill. The new ore-shoot contains 200,000 tons. Instead of screening the ore as before, the crusher product is sent direct to a combination mill designed by the owners, which reduces 300 tons daily, using 65 hp. With Tonopah people W. & M. have bonded the Wall claims near the Manhattan Summit. Prospects are good.—The Train & Chase lease on the Mustang is producing \$100 ore. The shaft is down 225 ft. on the incline, showing improvement.

In the past six months the Big Four lessees had four lots of ore treated, yielding \$40, \$49, \$52, and \$125 per ton, respectively.

New ore-shoots have been opened on all levels below 250 ft. in the Union Amalgamated. The ore milled improves steadily.

The Commercial company, and lessees Nelson & McFarland, Ray & Kryder, and on the Seyler-Humphrey report good results.

ROCHESTER. In the Four J workings of the Rochester Mines Co. a 4-ft. vein of \$35 ore has been cut, 200 ft. west of any other vein in the mine. The company is constructing a 2-mile aerial tram from the mine to the mill, thus dispensing with the ground tramway. Machinery to bring the mill's capacity to 200 tons is now arriving.

SEVEN TROUGHS. After unwatering its 1700-ft. level the Coalition company has resumed mining. No great damage was done by the water.

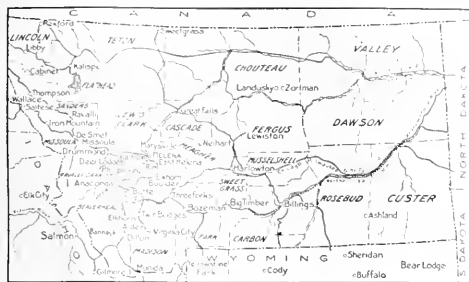

TONOPAH. Ten mines last week produced a total of 9247 tons of ore valued at \$192,326.—During August the Tonopah Mining Co.'s yield was 8098 tons averaging \$15.50 per ton. The profit was \$59,570.—The Extension company has resumed sinking its Victor shaft to 1800 ft. depth.—The Tonopah Western Consolidated Mining Co. has been incorporated by Butte and Boston capital to develop 700 acres between the Tonopah Bonanza and Great Western properties. R. H. Gross of Boston is president. Important results are expected.

NEW MEXICO

MOGOLLON. The Socorro Mining & Milling Co. shipped approximately 70,000 oz. of bullion from operations in August, and the Mogollon Mines Co.'s output for the period was over 50,000 oz., a total of more than 21 tons of gold and silver for the month, in addition to several tons of high-grade concentrate. From a portion of this district, 3 miles wide by 5 miles long, more gold and silver is being regularly produced than in all the remainder of New Mexico combined.

SOUTH DAKOTA

HILL CITY. The new mill of the Hill City Tungsten Production Co. is now receiving custom ore. The plant has a capacity of 150 tons of ore daily. It is part of the old Harney Peak tin mill. The process is as follows: storage-bin, jaw-crusher, 30 by 14-in. rolls, screens, Vexin sampler, elevator, storage-bin, pneumatic jig to remove mica (a nuisance in the Black Hills), screens, trommels, jigs, Willey tables, Deister-Overstrom slime-tables, and flotation and canvas plant for final treatment.

MAP OF MONTANA.

month. No. 4, in May 1915, moved 411,000 cu. yd. in 82½ running time. Eighty-five men are employed to operate these four boats including office, etc. In 1915 the cost per yard was 5.99c., on an excavation of 3,632,677 yards. Little success has been reported from attempts to dredge outside of these districts of Montana.

NEVADA

(Special Correspondence.)—The Eureka district, one of the oldest in Nevada, again reports considerable activity. The Eureka Mining Bureau has been formed to assist operators and investors. The California mine is being vigorously worked by lessees, and shipments of \$40 to \$50 ore are made. New shoots have been found in the vicinity of the rhyolite, an unusual occurrence in this district. Similar conditions prevail at the Mortimer.

A new shaft is being sunk at the Connolly and mine buildings are under construction. Several lessees are shipping good-grade ore. The property is worked by New York capitalists. H. G. Catlin is manager.

Other active properties are the Huebner, Marne, Bullwhacker, Barton, and Cyanide. Developments are particularly brisk on Prospect mountain and in California gulch.

Eureka, September 16.

(Special Correspondence.)—A fair potash deposit has been discovered by Henry Osborn and associates in Big Wash canyon in the south-western part of White Pine county. Numerous tests return 4½ potash. A bond has been taken on the deposit by San Diego people, and work started. An abundance of water is available.

Shipments of gold-silver-lead ore are being made from the Elliott property at Lyon Springs, near Kimberly. The mine produced rich ore years ago, but has not been active for a considerable period. It recently passed into the hands of W. S. Elliott, formerly of Goldfield.

Tungsten mining at Bonita continues active. The Bonita group is producing scheelite and the mill is working steadily. John B. Tilford is managing-owner. Some ore is going to the mill from the Richardson and Poppish mines. Prospecting is active.

Ely, September 8.

BATTLE MOUNTAIN. We have received information from Breitung & Co. Limited of New York that it has purchased the Plumas Goodwin group of claims in the Galena district, 12 miles south-west of Battle Mountain. The property is to be further developed.

GOLDFIELD. Final figures of the Goldfield Consolidated for July are as follows: 26,700 tons of ore gave a profit of \$30,016. Net costs amounted to \$5.63 per ton. Development covered

An interesting feature of the district is development of the Cowboy mine, which is estimated to contain 600 tons of 1.6% tin ore.

UTAH

ALTA. At a depth of 289 ft. the diamond-drill has passed through brecciated limestone in the Emma mine. Another hole has been started 50 ft. south. The geological results are watched with interest.

As ties and rails for the Salt Lake and Alta railway have been delivered at Wasatch it is expected that the new line will be complete within a month.

The Wasatch Mines Co. has finished the open-cut for the portal of the 4000-ft. adit to be driven, and machine-drills are now pushing ahead in solid ground.

TINTIC. August profits of the Iron Blossom were \$15,000, in spite of small shipments on account of the smelter embargo.

The Grand Central company is to use electric motors for hoisting and air-compressing. C. E. Loose controls this property.

A recent carload of ore from the Gemini realized over \$13,000. The assays of two lots returned 0.04 oz. gold, 628.63 oz. silver, 2.33% copper, and 9.6% lead; and 18 oz. gold, 5730.7 oz. silver, 6.15% copper, and 15.8% lead.

WASHINGTON

SPOKANE. Transactions on the Stock Exchange are as follows, dealings being done in Idaho, Washington, and British Columbian shares: January, 922,397; February, 780,823; March, 1,651,794; April, 1,708,191; May, 1,310,220; June, 867,836; July 266,135; and August 809,800 shares.

VALLEY. At the Spokane Belle silver mine, 32 miles north of Spokane, E. H. Belden has opened a deposit containing 20% of tungsten. The formation is granite and schist.

CANADA

BRITISH COLUMBIA

SILVERTON. In the Alpha adit of the Standard company the face now shows 9 ft. of galena that assays 75% lead and 200 oz. silver per ton, also some grey copper. The extent of the shoot is not yet known. The July profit was \$56,609. Sales of lead amounted to \$47,775, and of zinc \$63,890. Dividend No. 44 absorbed \$50,000. The balance on August 1 was \$296,381.

ONTARIO

COBALT. During August the Nipissing company produced silver worth \$203,898, from the treatment of 152 tons of high and 7254 tons of low-grade ores. The refinery shipped 306,051 oz. of bullion. At a depth of 425 and 520 ft. in No. 81 shaft the Cobalt Lake fault was encountered. It is 12 in. wide, containing calcite, and from 4 to 6 oz. silver per ton.

PORTFOLIO. Following is the Dome record for the current year:

	Tons	Gold yield	Value per ton
January	31,600	\$176,990	\$5.58
February	32,040	163,590	5.10
March	34,300	173,381	5.05
April	37,300	189,000	4.75
May	39,400	189,600	4.88
June	36,700	179,000	4.80
July	38,150	181,000	4.74
August	40,010	180,000	4.49

Costs were \$2.56 per ton during August.

In the four weeks ended August 11 the Hollinger mill treated 42,387 tons of ore averaging \$9.61 per ton. The profit was \$220,357.

The Porcupine-Crown company is sinking to 900 ft. At 850 ft. the main vein is richer than above.

A 150-ton mill is contemplated for the West Dome mine, where development has been very satisfactory.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

R. A. F. PENROSE is at Denver.

GEORGE F. OBER has returned from Hongkong to Seattle.

G. CHESTER MASTER is manager of the La Blanca mine at Pachuca, Mexico.

C. Q. PAYNE, of New York, was here this week, on his return from Oatman, Arizona.

HENRY JENNINGS is visiting the Mariposa grant, near Coulterville, California.

H. FOSTER BALN is going to China in October and is expected here on his way thither.

R. S. BURDETTE will be at San Antonio, Texas, until Mexican conditions are more settled.

E. T. MCCARTHY left London on September 4, going to the Spassky and Atbasar mines, in Siberia.

RENÉ E. RICKARD, assayer with the Seoul Mining Co., in Korea, is on his way to enlist in England.

FRANCIS CHURCH LINCOLN, Director of the Mackay School of Mines, has returned to Reno, Nevada, from Bolivia.

C. M. CAMPBELL, superintendent of mines at Phoenix, B. C., for the Granby Consolidated, is at Winnipeg, on a holiday.

WILSON W. HUGHES, formerly at Guanajuato, is superintendent for the Monitor Belmont Mining Co., at Belmont, Nevada.

T. W. GRUETTER has returned from Marysville, where the Yuba company is experimenting with his platinum-recovery process.

CHARLES F. WILLIAMS, formerly mining engineer with the Cananea Consolidated Copper Co., Cananea, Mexico, is now at Reno, Nevada.

FREDERICK G. FARISH, manager of the Lluvia de Oro Gold Mining Co., is on his way to Lluvia, Chihuahua, by way of Nogales and San Blas.

H. C. WOOLMER retires from the management of the Spassky and Atbasar copper mines, in Siberia, at the end of the current year, becoming managing director.

P. O. WELLS is at La Fundición, Peru, where he has erected a concentrator for the Cerro de Pasco Mining Co., to test its ores by gravity methods and flotation.

LYON SMITH, metallurgist with the Snyder Electric Furnace Co. of Chicago, has resigned to become assistant superintendent for the River Smelting & Refining Co. at Florence, Colorado.

H. R. HANLEY, formerly general manager of the Bully Hill mine, has been appointed superintendent of the zinc plant now under construction at Kennett for the Mammoth Copper Company.

HERMAN FLECK, for many years head of the chemistry department at the Colorado School of Mines, has resigned to engage in private business, being associated with the Chemical Products Company of Denver, of which he is one of the founders.

[Several inquiries have been received asking for a pamphlet edition of Mr. F. H. Probert's articles on the 'Superficial Indications of Copper.' We are glad to say that such pamphlets are now obtainable at this office for the nominal price of 50 cents.—EDITOR.]

ANTON HILL, the president of the South Keystone M. Co. of Amador City, died at his home at Spanaway, Washington, recently. He was a native of Germany, aged 63 years, and was identified with a number of large business enterprises in Tacoma, in addition to his Mother Lode interests.

THE METAL MARKET

METAL PRICES

San Francisco, September 19.

Antimony, cents per pound	11
Electrolytic copper, cents per pound	28
Pig lead, cents per pound	7.25-8.25
Platinum: soft and hard metal, per ounce	\$85-89
Quicksilver: per flask of 75 lb.	\$75
Spelter, cents per pound	12
Tin, cents per pound	41
Zinc-dust, cents per pound	29

ORE PRICES

San Francisco, September 19.

Antimony: 50% product, per unit (1% or 20 lb.)	\$1.00
Chrome: 45% and over, f.o.b. cars California, per ton	13.00-15.00
Manganese: 50% product, f.o.b. cars California, ton	12.00
Magnetite: crude, per ton	7.00
Tungsten: 60% WO ₃ , per unit	15.00

New York, September 13.

Antimony: This ore is firmer, but only small business has been done at prices ranging from \$1 to \$1.10, immediate delivery.

Tungsten: Business has been quieter. Small quantities are available around \$17 per unit, but most of the holders want \$20. In the recent export buying, probably 800 tons was taken for prompt shipment. Other negotiations are pending, but show a tendency to close very slowly.

EASTERN METAL MARKET

(By wire from New York.)

September 19.—Copper is active, prompt metal is scarce; lead is quiet, independents are bullish; spelter is quieter, though firm abroad.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
Sept. 13.....	68.00
" 14.....	68.25
" 15.....	68.00
" 16.....	68.25
" 17 Sunday.....	68.11
" 18.....	68.75
" 19.....	68.62
Monthly averages

July	54.90
Aug.	54.35
Sept.	53.75
Oct.	51.12
Nov.	49.12
Dec.	49.27

The above quotations indicate a market with a firm undertone, the fluctuations probably being due to demand and speculation.

Writing on August 21, Samuel Montagu & Co. of London said, "The amount of disposable silver has been so small, and the prospect of larger supplies coming out at an advance in price so slight, that buyers for coinage—a demand as implacable as ever—have not found it worth while to compete for what was offering. This policy was the more justifiable owing to the large amounts obtained from China recently, when sales were made freely from that quarter. During the week the China exchanges had a hardening tendency, and further sales seem unlikely at present. The hindrance to Mexican mining, which may be prolonged, will have the effect of further reducing the annual output, and a strong statistical position will be created. Demand promises to be more urgent than ever, especially should China be compelled to replace, or even more than replace, the heavy sales of the last year or so, while the quantity of supplies will be decidedly less."

COPPER

Prices of electrolytic in New York, in cents per pound.

Date	Average week ending

Tin is steady at 38.50 cents.

Eastern Metal Market

New York, September 13.

The market in general presents a better aspect.

Copper is active both on domestic and foreign account, and prices are stronger. Near-by metal is scarce, some of the producers having little or none to offer until November.

A great deal of zinc has changed hands, brass mills and export agents having been good buyers.

Independents have been taking premiums for prompt deliveries of lead, and it is anticipated that the leading interest will advance its quotations.

Tin has been dull and uninteresting.

The antimony market has continued to sag, and some producers are unwilling to sell at quoted levels.

Aluminum is stronger.

The iron and steel market continues to gather strength. A most serious problem for all concerned is that of deliveries. Small boiler-makers who do not buy far ahead are in distress for want of material, and some say they may close their shops. Eastern Pennsylvanian mills have inquiries for at least 75,000 tons of plates from consumers who fear that the Government naval program will absorb 1917 capacity to an extent which will leave them in the lurch. Prompt-delivery plates command 4c., Pittsburg. Now steel capacity in operation since January 1, or to be in operation by the end of the year, represents an additional tonnage of about 3,200,000 tons of steel ingots, yet it has made but little impression on the situation. The foundry pig-iron market is more active, but prices show little change. The metal-working machine industry is about normal.

COPPER

With producers asserting themselves to be well sold-up on near-by metal, some saying they have none to offer, that is, any quantity of consequence, this side of November, the making of prices for near-by deliveries has been practically left in the hands of re-sellers, and it begins to look as if the latter's stocks were becoming small. Near-by metal is unquestionably scarce. September and prompt copper is held at 28 to 28.25c. by re-sellers, while first-hands quote 28c. for November, 27.75c. for December, and 27c. for first quarter. Domestic consumers have been active in purchasing fourth-quarter metal, and there are in existence many inquiries calling for that position. The market has been strengthened by the placing of new orders for brass rods and other munitions' materials, while the Allied governments are negotiating for a large quantity of copper, stated to be 125,000 tons. The contemplated order has been under consideration for some days, price apparently standing in the way of its consummation. It is reported that Great Britain is willing to pay 26c. Late last week Russian interests placed an order for 5000 tons. The foreign business is mostly for 1917. For some October metal for shipment to Russia, 28.50c. was paid. The brass and copper mills are busier than they have been at any time in recent months. Two or three are out of the market for the remainder of the year. For rods, one interest asks 39c., although up to the present time others have asked 34c. Many of the rod mills are using brass turnings, which are suitable providing they do not contain over 3% of lead. France, through J. P. Morgan & Co. has been an eager buyer of these turnings. Brass wire is difficult to procure. It is quoted at 38 to 39c. per lb. The London copper market is stronger. Spot electrolytic, the base of quotations, was cabled yesterday at £132 against £130 a week previous. Exports from September 1 to 13 totaled 10,472 tons.

ZINC

The market has been active in the past few days, and a large quantity of metal has changed hands. Foreign interests have

bought heavily, while the domestic brass mills have placed orders to cover new War orders. Prompt zinc was quoted yesterday at 9.25c., New York, and 9c., St. Louis. For last quarter about 9.12c. New York, and 8.87c. were asked, and paid. Near-by metal is scarce, not so much because of any actual shortage, but because of the disposition of producers to hold rather tightly to what they have. There is a feeling on their part that higher prices are logical to expect. A strengthening influence on the market is a prospective demand from Canada to fill a large munitions' order. It is said that the order will require 50,000 tons of prime Western, but the business has yet to be placed. Strength also has been imparted to this market by an advance at London, where the spot quotation yesterday was £52, against £49 a week previous. A London authority says that a fair business has been done in Great Britain at "very full" prices for early delivery, and that the Allied countries have bought for early shipment; also that the European markets will be chiefly influenced in the near future by sailings from America, which at present are most unsatisfactory. Exports to the 13th totaled 4015 tons, showing that heavy shipments are being maintained. Sheet zinc is unchanged at 15c., f.o.b. mill, carload lots, 8% off for cash.

LEAD

Briefly the situation is that the leading interest is not selling except to regular customers, and then only in restricted quantities, while independent producers are getting premiums. The principal producer's nominal quotations are 6.50c., New York, and 6.55 to 6.60c., St. Louis, a circumstance which has led to the prediction that the A. S. & R. Co. would announce an advance at an early date. Most of the buying has been for prompt and early deliveries. On the surface the market appeared quiet, but it gradually became known that a good business was being done, some of it with foreign consumers. In the case of a special transaction, 6.87c., Philadelphia, was paid. At London supplies are reported to be not over-plentiful. The London quotation for spot yesterday was £30, or £1 less than a week previous.

TIN

The market has been dull almost continuously since the last report, but prices have remained fairly firm, despite weakening influences. One of these is the continued offering of Banca tin at prices considerably below those for Straits. Banca has been offered as low as 36.50c. Straits (spot) was quoted yesterday at 38.25c., but consumers were not interested. Most of them are supplied with metal for which not a few paid prices considerably above those ruling today. Arrivals this month, up to the 13th, total 865 tons; there is afloat 3980 tons.

ANTIMONY

The market continues to sag, and offerings are reported as low as 11c., duty paid. The dullness is most acute, and one large Chinese producer will not take business at present levels. Needle antimony is very scarce, and holders are quoting up to 16c. per lb. with the probability that they will get this price unless supplies are augmented by new arrivals.

ALUMINUM

The quotation for virgin aluminum, 98 to 99% pure, is strong at 60 to 62 cents.

IN THE HALF-YEARLY REPORT of the A. S. & R. Co., the president, Daniel Guggenheim, states that the profit (\$11,145,694) makes an abnormal comparison with earnings \$5,019,982 in the first half of 1916. Last year prices were depressed; this year the War produced a reverse effect. Costs have advanced considerably.

Book Reviews

HOW TO BUILD-UP FURNACE EFFICIENCY. By Jos. W. Hays. P. 156. Ill., index. Jos. W. Hays, publisher, Rogers Park, Chicago, 1916. Price, \$1.

This work is in its 10th edition, revised and enlarged, and is described as a hand-book of fuel efficiency. This is an important topic, frequently discussed in technical papers, and the subject of numbers of text-books. The author apologizes for the frequent use of the personal pronoun, but says that the whole book is the result of his own experience. The author speaks straight out on boiler firing, and engineers should find something of value in the book. Some of the sketches are out of the ordinary.

THE PHYSICO-CHEMICAL PROPERTIES OF STEEL. By C. A. Edwards, professor of metallurgy, Manchester University. P. 226. Ill. Charles Griffin & Co., Ltd., London, and J. B. Lippincott Co., Philadelphia, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$3.50.

This is a well-written book, thorough, and comprehensive. Much information has been sifted into readable form. The chemical and structural constitution of steels is described, likewise the internal changes that occur when steels are heated and cooled under varying conditions, and the transformations of the iron-carbon system. High-speed tool-steels and the various alloy steels are discussed, also the theories of hardening steels, and the effects of sulphur and phosphorus.

MOLESWORTH POCKET BOOK OF ENGINEERING FORMULAE. 27th edition. P. 865. Ill., index. Spon & Chamberlain, New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.50.

This standard English pocket-book has been thoroughly revised for the latest edition and an electrical supplement has been added. To those who are unacquainted with the source and character of the book, we might say that if we took Trautwine, and added a dash of both Kent and Foster and boiled down the mixture, eliminating much of the text and leaving little besides the tables and formulae, the final result would be similar to the present volume. Part of the contents is, naturally, more applicable to English than to American practice, but most of it is equally useful in both countries.

TACHEOMETER SURVEYING. By M. E. Yorke Eliot. P. 145. Ill., index. Spon & Chamberlain, New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.

The American engineer is so used to considering a transit as incomplete without a vertical arc, level on the telescope, and stadia hairs, that it might be well to explain that a transit without these attachments is called a tacheometer in England. The book is devoted to a thorough explanation of the elementary principles of stadia surveying, which the author states is not sufficiently treated in the standard English treatises on surveying. However, the material contained in the present volume is similar to that contained in several American books. In fact, the book is of slight interest to American engineers except as indicating that English practice is far behind American in some branches of surveying.

PRACTICAL SAFETY METHODS AND DEVICES. Manufacturing and engineering. By George Alvin Cowce. P. 434. Ill., index. D. Van Nostrand Co., New York, 1916. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$3.

If all the safety-first publications issued regularly by large corporations and the new books on the subject are studied by employees and the public, valuable results must follow.

Statistics are proving this so, but more lessons are needed. In the preface the author states that industrial accidents in the United States cost 35,000 lives and \$500,000,000 yearly. Also 350,000 injuries; while the minor accidents exceed 2,000,000. In the volume under review, accompanied by well-chosen pictures, the chapters deal with safety committees, buildings and fire, boilers, engines, elevators, electricity, shafting, belts and ropes, grinding tools, iron furnaces, handling materials, construction, railroads, mining, and explosives. Hand in hand with safety goes sanitation, welfare work, and first-aid, which are here well discussed. A useful book for mining and industrial companies' safety departments.

ELEMENTS OF MINING. By George J. Young. P. 628. Ill., index. McGraw-Hill Book Co., New York. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$5.

The author has fulfilled his promise when he says, "the objective of 'Elements of Mining' is to give the reader a comprehensive view of the mining problem." Although the book does not contain a great deal that is new and original, it does present a vast amount of valuable information not usually found within the covers of a single volume. It is more a compilation of known and useful facts than a treatise on the problems of mining.

Simple problems of geology and different types of orebodies are discussed in such a way as to be useful to the prospector as well as to the engineer. Considerable space has been devoted to the subject of boring and drilling. Machines used in diamond drilling, prospecting for oil and metal mining are discussed and illustrated. Separate chapters have been written on Rock Breaking, Transportation, Hoisting, Mine Drainage, Ventilation, Timbering, Different Types of Mining, Developments, Stopping, Organization, Costs, Accounting, Accidents and Miners' Diseases, and Examination of Mineral Deposits.

A better book could not be found by anyone desiring an encyclopedia of useful and practical information such as is needed in solving the problems encountered every day in mining operations.

ECONOMIC GEOLOGY. By Heinrich Ries. Fourth edition. P. 856. Ill., index. John Wiley & Sons, Inc., New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$4.

While the arrangement and method of treatment remain the same in this edition, considerable revision and additions have been made to the book. Many new illustrations have been added. The statistical data have been revised and brought up to date, as well as the complete bibliography to be found at the end of each chapter. The book is divided into two parts, one dealing with non-metallic minerals and the other with ore deposits. Considerable space has been given to the discussion of coal, with brief mention of the new fields in Alaska and Canada. The two opposing theories of the origin of petroleum—organic or inorganic—are fully discussed. Separate chapters are devoted to the consideration of cement, clays, lime, building-stones, salines, fertilizers, abrasives, asbestos, graphite, underground waters, and the minor minerals. The different types of ore deposits, the theories of their formation, and their classifications, are thoroughly and clearly discussed. Of particular interest is the section dealing with veins, the alterations, chemical reactions and secondary enrichments taking place in them. Typical and well-known deposits of the metals are cited and described to furnish examples of the theories of ore deposition. The chapters on the ore deposits of iron, copper, lead-zinc, silver-lead, gold, and silver have been considerably enlarged to include modern practice and recent discoveries. The more important minor metals as tungsten, mercury, nickel, cobalt, antimony, aluminum, and manganese have been given considerable attention. The book especially recommends itself as a valuable reference work, clearly and concisely written, with an unusually complete bibliography.

Recent Patents

1,182,320. METHOD OF TREATING FLUE PRODUCTS. Francis C. Ryan, Hammond, Ind., assignor of one-half to United States Metals Refining Company, Chrome, N. J., a Corporation of New Jersey. Filed Feb. 24, 1914. Serial No. 820,650.

1. The method of treating flue products, or other finely divided mineral bearing materials consisting in roasting the materials with excess of sulfuric acid, boiling the roast in an acid solution, separating the solution, precipitating basic salts by the addition of sufficient quantity of a neutralizing agent to leave the solution slightly acid, and separating the solution from the precipitate for further treatment to recover the metallic values therein.

1,192,806. ORE-CLASSIFIER. William Henry Weigand, Trojan, S. D. Filed June 19, 1914. Serial No. 846,080.

1. In a classifier, a concave vessel having a raised central outlet, a nozzle in said outlet, a plurality of annular, upwardly-expanding frustocone-shaped members removably associated with each other and with said nozzle and forming therewith a funnel, the level and size of which funnel in the vessel may be varied by means of said removable frustocone-shaped members, and a stirring mechanism associated with the vessel and adapted to direct the mass within the vessel from the central outlet toward the periphery of the vessel.

1,184,585. PROCESS OF TREATING ORES. Edward Harrison Snyder, Pioche, Nev. Filed Mar. 31, 1915. Serial No. 18,355.

1. A process of treating oxidized ores containing lead, zinc and other metals, which comprises leaching the oxidized ore with a hot liquid containing an alkali sulfate, and containing sulfuric acid in amount sufficient to dissolve a part only of the zinc contained in said ore, separating the resulting liquid from the ore, and rendering the same slightly alkaline to precipitate zinc hydroxide, treating the digested ore with a strong solution of caustic alkali to extract a further amount of zinc from the ore, and adding to the liquor thereby produced, an acid in amount at least nearly equivalent to the alkali present in said solution, to precipitate lead therefrom.

1,195,698. PROCESS OF CONCENTRATING CARNOTITE SANDSTONE. Herbert N. McCoy, Chicago, Ill. Filed Feb. 12, 1916.

1. A process of concentrating carnotite sands, which consists in subjecting the grains thereof to a process of attrition, and separating the value-bearing slime from the denuded grains, in water.

Industrial Notes

Information supplied by the manufacturers.

The Venturi Waste-Detector

A useful piece of apparatus for the detection of leakage and waste from the distribution mains and services of a water system, towns or mines, has recently been perfected by the Venturi Department of the Builders Iron Foundry, Providence, Rhode Island. It consists of two Venturi-meter tubes, having different but over-lapping ranges in measuring capacity, together with a mercury manometer, the whole being mounted on a frame. The smaller meter-tube is on a by-pass line above the larger tube. The manometer is of the barometric type. The inlet pressure-chamber of each meter-tube is connected by small piping to the mercury-well at the base of the instrument and the pressure from the throats of the meter-tubes communicates in a similar manner with the interior of the vertical glass-tube. The mercury is thus caused to rise and fall in the glass-tube in proportion to the difference between the inlet and throat pressures. The corresponding rates of flow in gallons per minute, or other units, may be observed on the fixed scale, the graduated portion of which is 22 in. long.

When a leakage test is conducted, the section is isolated from the general system by closing the main shut-off valves. A hydrant on the isolated main pipe is then connected by a hose line to the outlet end of the waste-detector. The inlet end is similarly connected to another hydrant entirely outside the district, the supply from which, therefore, must pass through the detector into the isolated main. This work can be done to the best advantage during the late hours of the night, when the use of water for domestic and other purposes is a minimum and when there is the least likelihood of drafts that may interfere with observations. Water is passed through the larger meter-tube first, and if the flow is so small that it fails to give satisfactory observations on the manometer, it can be diverted through the smaller meter-tube.

All possible intermediate gates are then closed successively and the changes in the manometer readings noted. Thus sensitive observations may be secured upon the amount of flow and especially upon the changes in the rate of flow into the isolated district as the various parts of the system are successively isolated. In this way the points where leakage or waste occurs may readily be determined.

The CHICAGO PNEUMATIC TOOL Co. sends us the following drilling results:

Some interesting tests of 'Hummer' drills were made recently in the igneous mica rock which is being excavated at the corner of East 149th street and Eagle avenue in the Bronx, New York. The first test was made with a type A66 little Hummer, using $\frac{1}{2}$ -in. hexagonal hollow steel, collared drill, with the following result: 20-in. hole, in 2 minutes 7 seconds; using $\frac{1}{2}$ -in. starter; 16-in. hole, in $1\frac{1}{2}$ minutes, second drill, $\frac{1}{2}$ in.; total, 36-in. hole in 3 minutes 37 seconds. The second test was made with a type C66 big Hummer, using $1\frac{1}{2}$ -in. hexagon hollow steel, collarless drill, with the following result:

	Length of drill inches	Kind of bit inches	Depth drilled inches	Time occupied min. sec.
Starter	30	*2 $\frac{1}{2}$	24	2 10
Second	54	†2	26	2 15
Third	62	†1 $\frac{1}{2}$	34	3 10
Fourth	120	†1 $\frac{1}{2}$	36	4

Total 120 11 35

EDITORIAL

T. A. RICKARD, Editor

WHILE gold is depreciating, in terms of supplies, the labor-unions in gold-mining districts are agitating for a further increase of wages, mainly because the copper miners are being better paid.

MACHINERY for use in the Siberian and Ural gold-mining districts will be admitted free of Russian customs duties for the next ten years, according to a recent decree issued by the Minister of Commerce at Petrograd.

PRESIDENTIAL years are usually considered to mark a period of low-pressure business activity, but this year the approach of the election synchronizes with optimistic expansion. This is due, in part, to the recognition of the fact that no alarm is felt over the selection to be made in November.

OUR contemporary at New York, through the McGraw-Hill Publishing Co., has issued a book called 'The Flotation Process,' ignoring the fact that this title had been used for a book copyrighted by another publisher. Apart from the legal question, we desire to record a protest against this breach of good custom: the title of a previous publication should be respected, to avoid confusion and prevent imposition.

ENGINEERS and other representatives of capital sent to Bolivia to look for new mining business report that it is difficult to make a deal on the basis of developed ore, most of the likely-looking prospects having no reserves of ore or not enough to warrant purchase for the large sums in cash asked by their sanguine owners. Good opportunities exist for those willing to take hold of prospects and bring them to the next stage of development.

ANACONDA's electrolytic zinc refinery at Great Falls is making good progress, the second section, out of five, having been set to work this week. It is expected that the entire plant will be in operation early in November, producing 2500 tons of spelter per month. The first section, using 144 cells or 'tanks,' is yielding daily from 20 to 25 tons of cathodes, which are sent to Anaconda to be melted, the furnaces required for this purpose at Great Falls not having been completed. Another electrolytic zinc plant, that at Trail, across the line in British Columbia, is now producing 25 tons of spelter per day and is increasing this output as the stages of construction are slowly completed to a capacity of 100 tons daily. The electro-chemical process is the same at Great Falls as at Trail, and in each the product is a metal of great purity, which is destined to command the

market for high-grade spelter. In both localities also the cheapness of production is conditioned on the low price of electrical energy, the power-plants being controlled by the smelting companies themselves.

AMONG the curiosities of the War is the refusal of the Australian miners at Kalgoorlie to work with Slavs holding provisional certificates of naturalization issued by the Russian consul. Patriotism is expressed in a variety of ways, but we question whether this is one of them. The essential patriots have already gone to the front from Australia, so that these sensitive souls consist largely of 'slackers' or those unfit for military service. The truth is, this action at Kalgoorlie is a protest of the local labor-union against the employment of foreign labor and an effort to eject such labor from the West Australian goldfields. We are glad to add that the strike was short-lived.

DIAMONDS and other precious stones to the value of \$35,433,811 were imported into the United States during the first eight months of the current year, this amount being \$9,000,000 in excess of importations during the whole of last year. The wholesale value of these gems is about \$50,000,000 and their retail value about twice as much. As *Commerce and Finance* says, "there is no particular point to these figures except that they emphasize our extravagance." Our contemporary estimates American contributions to the various European relief funds at 5 cents per capita and the spending on jewelry this year at \$2.50 per capita, and on candy about \$2 per capita. The comparison is not pleasant, but it is true that America gave to Belgium more than money; executive ability of the highest order.

STATEMENTS are current that in Germany zinc is being substituted for copper as an electric conductor, more particularly in buss-bars. The conductivity of zinc at the ordinary temperature is about one-third that of copper and its melting-point is lower, but the chief objection is the tendency of zinc to re-crystallize under stress when used for overhead transmission of electricity. It has been suggested that a core of iron wire with outer strands of zinc be used; a steel core with aluminum strands has been employed in this country. The Germans are also using steel conductors, but this is not new; galvanized iron (more accurately, steel) wire has been used for some time in this country; when using thin wire for transmitting low voltages, the greater tensile strength of steel gives it an advantage; but for high voltages the relatively greater thickness, and weight, of

the steel wire renders it objectionable. The skin effect and corona hinder the use of iron and steel wire, particularly on high voltages. The choice of wire for a new line of electric transmission is determined nowadays only after consulting graphic diagrams showing the ratios of cost, quantity, and efficiency of the various metals usable.

COPPER received another impulse from the big deal made at New York last week, it being announced that 200,000 long tons of the metal was sold, at a little under 27 cents per pound, through J. P. Morgan & Co., to the British government. This purchase involves the sum of \$120,000,000 and represents about one-quarter of the annual production of copper in the United States. Domestic consumption also is active, the brass and wire mills having come into the market with large orders. The good fortune of the mining companies is checked only by the capacity of the refineries, which is being taxed to the limit. The erection of new plants for the purpose cannot be accomplished rapidly. At the beginning of this year the total refinery capacity was about 85,000 tons of metal per month and in September it had increased to 90,000 tons, and plant for 10,000 tons more per month is under way, but the monthly production is now 75,000 tons of American copper, to which must be added about 14,000 tons of imported crude copper, chiefly from South America and Mexico, that comes to this country to be refined.

TAXATION of mines under the British flag has become so burdensome owing to the War that a meeting of representatives of the industry was held in London on August 8 to discuss the question, under the chairmanship of Mr. J. H. Corder-James. Special objection is taken to levying the Excess Profits Tax on gold mines, which suffer from the rise in prices occasioned by the War, and the output of which, so necessary at this time, would become restricted if penalized by the proposed tax. The meeting had been convened by the Institution of Mining and Metallurgy, of which Mr. Corder-James is one of the vice-presidents. He made a clear statement of the case and referred to the joint request made by the three mining and metal societies to the Imperial Government, asking for the establishment of a Department of Mines and Minerals. This would be a great step forward in co-ordinating information and, more particularly, in recognizing the part played by mining in the economies of the Empire. Not much could be done at this first meeting, but a committee was selected from among the leaders of the non-ferrous metal mining business centred in London. We give the names because they were selected by a special committee of the Institution and indicate 'Who's Who' in the financial world interested in gold, silver, lead, tin, and copper mining at the British metropolis. The committee consists of Lord Harris, Sir Lionel Phillips, Sir Alfred Mond, Sir Trevor R. Wyne, Messrs. F. W. Baker, Edmund Davis, F. A. Govett, F. H. Hamilton, Henry C. Taylor, Leslie Urquhart, Oliver Wethered, and Robert Williams.

Copper Quotations

We have received a couple of letters asking us to explain why our average quotation for copper in July was 25.66 cents per pound while that of our contemporary at New York was 23.86 cents. A similar query was addressed to the editor of the *Engineering & Mining Journal*, and his reply was that he quoted "always the major market, i. e., the sale of the bulk of the copper. If somebody else did not have such comprehensive data as we have every week, and consequently gave undue weight to the relatively small sales of copper for prompt delivery, he would get a higher average than we would on the bulk of business." Our own reply has been delayed by the absence of the present writer in British Columbia. We reply now.

The prices reported to us by our New York correspondent, who is not connected directly or indirectly with any dealers, brokers, or producers of copper, are intended to be a guide to the consumer, not to establish a basis for contracts, whether for ore or labor, legitimate as this may be. As to that we must postpone discussion until next week. We give the average of prices prevailing for prompt or near-by metal, thereby fixing a definite and tangible base. When prompt or near-by metal becomes so scarce that excessive premiums are asked, the delivery quoted has been advanced to include a more marketable position. The determination of this is largely a matter of good judgment, just as all market-reporting involves sensing a situation. In other trades the usual basis of quotations is the price of material for prompt or early delivery. The matter becomes complicated when future months and quarters are considered; these are treated in the text of the market report, which we publish weekly with the quotations. The editor of our contemporary says that he quotes "always the major market," meaning the sale of the bulk of copper. His returns from the producers and selling agencies must be very complete indeed if he can determine what constitutes the bulk of sales and their deliveries and prices. The sellers must bare their very souls. And their unanimity! Usually in market-reporting, where you find one man like an open-faced watch, you find ten of the hunting-case variety. It is true that the bulk of copper is sold under contracts specifying deliveries several months away, but it is true also that some choice business is done in comparatively near deliveries, and at high prices. Further, spot metal does not usually consist of 'seconds' or re-melted copper. The producers ordinarily can furnish some 'spot,' there are also dealers that buy to hold for higher prices—speculators they may be termed—also manufacturers that have overbought and are tempted to sell on an advance. All these are factors at times. As already stated, a quotation for prompt delivery is something definite, in contrast to an average price for unspecified future deliveries at a time when sales might be made for delivery in October, November, December, the last quarter, first half, and so forth. Of what use can such quotations be to a con-

sumer, and if they are not for the consumer, why not say so?

A letter from Mr. Walter Douglas has been featured in the Arizona press, and a copy of it has been sent to us. He explains why his company and others have adopted the *Journal* figures in their sliding-scale agreement with the miners. He says that the quotations of the *Journal* are "as accurate as it is humanly possible to compute them," and he compares them with those received for copper sold by Phelps, Dodge & Co. His evidence is not convincing. In 1915 the *Journal* average was 17.27, while Phelps, Dodge & Co. received 16.05 cents per pound. A discrepancy of 1.22 cents suggests inaccuracy somewhere. Referring to the *Journal's* July average of 23.865, he says that "the producing companies have been receiving, during that month, a considerably higher price for the copper which they delivered." Did they receive the 25.66 quoted by us? Certainly July was a dull period, but we do not believe that the bulk of sales went on the *Journal* average for the month, especially in view of the fact that the producers were declared to be well sold ahead and in a position where they could afford to lean back while re-sellers made their sacrifices. It is in periods of dullness that second-hands become uneasy and endeavor to force sales by offering commissions. Later in the month the re-sale metal was pretty well absorbed, and small producers were suspected of using the dealers to get business, thereby saving their own face. Ostensibly they were holding the umbrella. All this was duly recorded in our market reports. Mr. Douglas acknowledges that there was little doing that month. We have every reason to believe that our quotation reflected conditions accurately.

A Successful Engineer

On another page we publish an interview with Mr. J. Parke Channing. This, like similar autobiographical records, conveys several lessons, more particularly to the younger members of the profession. To those experienced in mining the interview does not need to be recommended, for Mr. Channing's reputation is such that anything he says is sure to provoke keen interest, especially when he has been driven by the editor into a reminiscent mood. The story of this engineer's life is an endorsement of a special training. Mr. Channing is a representative product of the Columbia School of Mines. Having known a number of the men in his class at Columbia and in the classes immediately preceding or following that of '83, we have concluded that the 'early eighties' was a good time for the incubation of talent at our premier mining school. In analyzing the causes contributing to the professional success of the Columbia men at that time, more especially, we have decided that it was due to two factors: first, they came from the older mercantile communities of New England, from New York or Boston, from among families endowed with keen wits and business acumen. In later years the Columbia Mines students have been recruited from all over the continent, but thirty years ago the attendance was pre-

dominantly from the Eastern seaboard. We are more certain about the second factor: an excellent schooling in mathematics. "Do ye ken Van Am?" Undoubtedly the thorough mathematical teaching given to two generations of graduates by J. H. Van Amringe played a notable part in giving the United States a number of highly efficient men, in every walk of life, particularly engineering. For instance, in the latest victim to our interviewing campaign, we detect the ability to employ mental arithmetic, skill in selecting salient figures and making correct inferences therefrom, and above all, that constructive imagination whereby the engineer can foresee his work before he starts to do it. Mr. Channing is an assiduous collector of information on technical subjects, and he is a willing exchanger. He has the co-operative trait, which blesseth him that giveth no less than him that receiveth. We have been told by some friends of his, with whom he pioneered the first automobile into the Nevada desert, that he has the quality of persistence and indubitable skill as a mechanic. On that memorable occasion—12 years ago—he exhibited the marks of a 'good sport,' under trying conditions. We know that he has the sense of humor, without which life would be a Nevada desert, for he tells Cornish stories with a verisimilitude that would deceive anybody not born at Camborne or Redruth. But he learned more than this from his Cornish friends in the copper and iron regions. He imbibed some of their inherited sense of mining when in his younger days he consorted with such worthies as John Daniell and Joseph Sellwood; and yet he escaped the reactionary conservatism of the Cousin Jack, as is indicated by his effort to get the Calumet & Hecla staff out of a weary rut. That was a striking episode in his career. We sympathize heartily. His criticism, then and now, was thoroughly sound. It is delightful to see the young man whom those Bourbons of mining denounced, because he tried to introduce progressive methods, able now, by reason of success and reputation, to pay them his compliments. It appeals to our sense of justice. Since the date of our interview, the Calumet & Hecla deal for the purchase of the Tamarack has been declared off. Next we come to copper mining in Utah, Nevada, and Arizona. Each of these episodes proves the value of cumulative observation and experience. Acquaintance with copper deposits at Butte and Clifton permitted Mr. Channing to come to a quick decision as to the value of the Highland Boy mine. In the Tennessee undertaking, he drew upon his Lake Superior experience of mining and his Montana experience of smelting so as to incubate a highly profitable enterprise. Again, the Nevada Consolidated story shows how the three days spent at Clifton, with its hint as to how a disseminated copper deposit could be exploited to advantage, paved the way for another success. Incidentally, it makes a mining engineer feel old to recall the days when a 2 or 3% copper orebody made capitalists sneeze. Only a dozen years have passed, but a great change has come over the face of the copper industry. Finally, we have the Miami story. That suggests that if you throw your bread on the waters it may return to you buttered

after many days. In short, a small incident may be fruitful of big results. Above everything, it proves the usefulness of a knowledge of men: of becoming acquainted with as many of the personnel of mining as possible. Thus the chance meeting with Mr. Alsdorf in 1885 gave Mr. Channing the opportunity 11 years later to develop and exploit the Miami mine. He made fine use of it. The Miami business likewise illustrates the successful working of an exploration company, and the manner in which, under proper guidance, such speculative ventures can be made highly remunerative. The reader will find that the interview closes with interesting replies to some of our leading questions. The American mining engineer nowadays does, we believe, spend more time underground than he used to do twenty or thirty years ago. We agree with Mr. Channing that it is there—in the finding and breaking of ore—that the best scope for economical betterment is to be found. Yet, we query whether metallurgical ingenuity has been exhausted. The revolution made by the flotation process is too recent for the belief that we have reached the limit of perfection in that art. As to the finding of ore, all we know is small indeed when compared with the knowledge we lack on this vital subject. There is also the basic problem of human efficiency and the adjustment of the human relation between employer and employee. In this department Mr. Channing takes a keen interest. He has contributed, in many ways, to the campaign for 'welfare.' In matters appertaining to his profession, he has proved public-spirited. For instance, he was a founder of the Mining & Metallurgical Society of America, an organization that, like the Progressive party, was destined to discipline the older institutes rather than lead its members to see a higher light. Mr. Channing has taken part in the effort to reform the mining law. In short, he has shown how a mining engineer can be a highly specialized instrument of industry and also a good citizen. He has justified his education.

Suggestions to Authors

In this issue we publish a lengthy excerpt from a bulletin just issued by the U. S. Geological Survey in which the official editor of the Survey's publications, Mr. George M. Wood, has embodied much excellent advice to the members of the staff on the writing of geological reports. We have selected that part of the bulletin which seems most immediately interesting and useful to our own readers. That it will prove useful we have no doubt; advice of this kind is badly needed among mining geologists and others; therefore we take particular pleasure in giving publicity to Mr. Wood's brochure. We recommend our engineering friends to write to the Director of the Survey and obtain a copy of this publication. It contains a great many valuable hints and much pertinent suggestion. Numbering ourselves among those anxious to improve the expression of technical information in writing, we are glad to find so little with which to express disagreement from the editor of the

Survey. Only in one detail do we differ: he seems to have scant appreciation of the function of the hyphen. An editor that approves 'clay slate,' 'basalt tuff,' 'field notes,' 'rewriting,' 'surface water,' 'building stone,' and 'oil lands' must have no more use for a hyphen as a mark of connection than a patriotic American in a political campaign. Mr. Wood explains the scheme adopted by the Survey for the employment of hyphens in petrographic names, but it does not commend itself, and his ignoring of the hyphen where it is clearly demanded warrants the belief that he misunderstands the use of it. But in that respect he is not singular. The discriminating use of the hyphen would do a great deal to improve the clearness of technical writing, in which the compounding of words is so frequent by reason of the effort to be concise. However, that is a minor matter. The advice quoted in four pages of this issue represents only 9½ pages out of a pamphlet having 120 pages. We have reproduced the advice originally prepared by S. F. Emmons, with later revisions by Mr. F. L. Ransome, himself a geological writer of recognized literary distinction. 'Suggestions as to Expression' is the heading of another chapter in which general counsel of the most practical kind is offered to those desiring to learn how to improve their writing. Then come hints on the fundamental principles of composition, illustrated by quotations showing common blunders in construction. Words and phrases that are habitually misused are passed in review. We note with pleasure that the unintelligent use of 'value' is condemned and 'ore' is defined as 'mineral or rock from which one or more metals may be profitably extracted.' It is a notable step forward when the official geologist accepts this definition, for it was the idea of a mineral deposit without reference to its economic value that formerly caused so much confusion. A vein of quartz containing a trace of gold may be an interesting geologic structure, and the sinking of a shaft or the driving of a cross-cut into it may afford information of scientific value, but 'ore' it is not, because it cannot be exploited to advantage. This fact is recognized in the definition accepted by the Survey. Grammatical errors and problems are discussed in an enlightening manner; the author gives a summary of the features of a good manuscript; then typographic style, proof-reading and correcting, with directions for the typewriter, occupy the closing pages. There is no geologic information in this bulletin, nevertheless it constitutes one of the most valuable contributions of the Survey to the science of geology. Much current knowledge on the subject is either lost in turbid expression or discounted by inept writing. Sundry publications of the Survey itself, in former years more particularly, give point to such reflections. It would be ungenerous not to recognize that during the last two decades the style of the Survey's reports has improved to a level far above the average of the technical writing appearing in professional transactions and we do not doubt that the sincerity of purpose exhibited by the editor of the Survey in this publication has been a factor in promoting that result, of which the public has been the beneficiary.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Prospecting: A Suggestion

The Editor:

Sir—To the gentlemen who have discussed my suggestions on syndicated prospecting, which appeared in your issue of July 22, I freely admit that my ideas are open to criticism from the prospector. Frankly, I took the viewpoint of the investor who finances the prospector, the engineer, and all the contingent expenses. If my estimate that \$5000 would be sufficient to employ a party of from three to ten men as they were needed on a three months' prospecting trip seems too low, I can only say to those who differ from me that I would not undertake the business on such a bedrock basis unless I were otherwise disengaged. Nevertheless, from my own experience, I believe that the scale of compensation indicated would be a sufficient inducement for many men of the right kind, who would be glad to prospect on a daily wage with the assurance of a bonus of a thousand dollars in the event of a discovery.

In this hypothetical prospecting trip, financed by a small syndicate of investors who pooled their funds in sending a party of experienced men into one of the still open mineralized districts of the public domain, I assumed that the chances are in favor of their co-ordinated efforts resulting in the finding of an orebody that would make a dividend-paying mine. On the other hand, I discounted the loss by dividing it among 20 investors.

Let me quote two instances from experience. In the summer of 1900, after a couple of years' prospecting and other technical work in Alaska, I found myself 'out of a job' at Nome. Applying for work to the Wild Goose Mining & Trading Co., I was told that if I cared to 'mush' across country for nearly a hundred miles I could have the privilege of working 10 hours per day shoveling into sluice-boxes on Ophir creek for "five and board." I 'mushed.' A few weeks later, at the end of a long shift, I suggested to the superintendent that he send me with a helper into the hills prospecting, at the same wages as before. He agreed, and let me sink a few holes on a neighboring bench. From the third to the eighth hole, ranging from 10 to 18 ft. in depth, I found 'pay' in an old channel, with the result that sluicing operations in the streambed ceased for the time and the entire 'gang' was put to work running cross-cuts into this old channel and wheelbarrowing the richer gravel therein down to the sluice-boxes. While I flattered myself that I had made a rich strike, the superintendent took the natural view that I was entitled to

no more than my daily wage, and at that time I was glad to work on that basis. Since then, the Lane interests for whom I worked have increased their clean-ups materially by employing 'grubstakeless' prospectors to work similarly under the direction of their superintendents.

There would be a wider field today for experienced prospectors if mining companies would retain more of the prospector type of men. Undoubtedly there are rich deposits near many operating mines lying undeveloped because such exploratory work is not conducted as a 'side-line' by the management. A striking instance of such lack of perspective is given below, not in the spirit of criticism, but as a simple statement of fact.

Mr. John B. Platts, of Oatman, one of the contributors to this admittedly hypothetical symposium, will appreciate the following brief history of the Tom Reed mine in the Oatman district and the development of the orebodies adjacent to it. For a full decade the managements of the Tom Reed and Gold Road properties, two miles apart, were content to confine their exploratory work to the opening up of new orebodies within the limits of their respective boundaries. On the payroll of the Tom Reed company were two efficient miners, George W. Long and J. L. Melver. From their intimate knowledge of the vein in this mine they became convinced that the continuance of the ore-shoot would be found on adjoining property. Imbued with faith in their theory, they severed their connection with the company and sank a shaft on their nearby claims. In the summer of 1914, they won their reward at a depth of 463 ft. when they struck the continuation of the Tom Reed vein and opened up the bonanza orebodies of the United Eastern mine. All honor to such men of initiative! The success of such prospectors has made the West what it is today. Yet, there may be a possible difference of opinion on the part of their former employers. It is almost needless to state that in the light of their discoveries, the stockholders and managers of the Tom Reed property must realize that the company could have been the beneficiary of such a development on the extension of its vein had it employed Messrs. Long and Melver to prospect contiguous territory on the basis of a daily wage. It may be said that under the wage system men of this type would lack incentive that leads them to explore. But I suggest that the miner working underground is actuated by much the same spirit as the free prospector. Every man who is worth his three or four dollars per day underground is

normally anxious to make a good showing, and many a wise manager gives such zealous miners more or less free rein to 'follow the ore' as their judgment dictates. When such men make a 'strike' they should be rewarded with a bonus in cash or stock that will inspire others to follow their example.

The conclusions to be drawn from these instances are obviously that the mining corporations may well afford to employ skilled miner-prospectors to explore other claims or properties on the basis of a fair wage and an equitable bonus in the event of their making a real discovery. That such procedure is becoming more practical is being demonstrated by the results of exploration companies, organized in some instances as subsidiaries of operating mining companies and in other cases financed by officials of the parent enterprise. The development of some of the rich deposits adjacent to the United Verde at Jerome was initiated by far-sighted salaried employees of the older corporation. There is a wide field still open for the exploration syndicate to systematize prospecting according to modern conditions of co-ordination and efficiency. Although the 'good old days' of the prospector have gone beyond recall, there is still a great deal of work for him to do if he keeps abreast of the times, even though his status of partnership with a 'grub-staker' is being changed to that of a skilled employee of a company engaged in thorough and systematic methods of searching for hidden mineral wealth.

HAROLD FRENCH.

San Francisco, September 18.

Blasting Practice at Chuquicamata

The Editor:

Sir--In the article on this subject, published in your issue of July 8, 1916, I find several errors that might lead one astray in planning blasting operations of this kind for the first time, using the method described.

The cost of churn-drilling per foot is given as \$9.80, which is \$2 more than the drilling of our 1200-ft. holes has cost, and the cost of driving is given at \$5 per foot. The actual costs are \$3.60 maximum down to \$2.50 minimum for blast-hole drilling. The tunnel-driving costs \$10 per foot, in place of \$5, the price to the contractor alone being \$5 per foot. The tunnel-blasting is very much cheaper per cubic yard of material blasted, for the reason that less footage has to be driven between charges and because the expense of springing operations in the case of the well-drilling is dispensed with.

The factor of 463 lb. for a linear metre of line of least resistance is not a fixed quantity, but varies from this as a minimum to 600 lb., depending upon the material to be blasted. The factor of 2.61 for 60% strength dynamite compared with black powder should read 2.25. The black powder referred to is manufactured in the country and compares in blasting strength to 40% dynamite in the proportion of 1:1½ by weight.

This ratio has been proved by repeated trials. The 60% being 1½ the strength of the 40%, would give the factor 2.25.

The plan of the wiring (Fig. 1, 3, and 4) is in error, the caps here shown connecting in multiple. The article describes the caps as being connected in series, but the plan does not conform.

Further along the article states: "From careful experiments it was found that for a series of 20 caps, a current carrying 0.75 amperes under 110 volts should be used for a successful 'fire'." This is an error, for the reason that experiments pointed out that by stepping up from one-fourth of an ampere the 0.75 of an ampere was the least current that would explode the 20 caps in series. From these and other experiments, and from experience in blasting, it was determined never to use less than a safety factor of 4, which would be three amperes.

In plan No. 1 it will be seen readily that should the charges loaded be blasted the collar of the shaft indicated would be lost in the slope resulting from the blast, with the bank height indicated, namely, from 24 to 30 metres. An entrance, therefore, to the second drift could not be effected. The spacing of 15 metres has since been increased to 30 with banks whose heights are at least 1½ times this distance.

As soon as the experimental stage of this method has passed and further blasting demonstrates the most efficient spacing, charges, etc., a paper covering the details of the work will be submitted for publication in the 'Transactions.'

The method is unique in that the usual method of tunnel-blasting, namely, the 'T' or 'gopher' method, is reversed, the entrance being placed well back of the working-face and the tunnels driven from cross-cuts to the face, so that access to the second tunnel is not delayed and steam-shovel work may be continuous.

Mr. Pope Yeatman suggested, soon after operations began at Chuquicamata, that a method of tunnel-blasting would probably be more economical if the details could be worked out, and that we ought to experiment with this end in view. The results obtained to date are far better than was even anticipated, and I wish to thank Mr. H. E. Treichler and Mr. James S. Wroth for their co-operation with me in bringing this method to its present development; also Mr. Burr Wheeler and Mr. Arthur Boynton of the electrical staff, for their assistance in conducting the many electrical experiments leading to the determination of the proper current, arrangement of wiring, etc.

It is unfortunate that a work of this kind should be presented to the profession before the method was completely developed and before complete data were available.

E. E. BARKER.

Superintendent of Mines for the
Chile Exploration Company.

Chuquicamata, Chile, August 16.

MACHINERY EXPORTS in July were worth \$18,971,052.

J. Parke Channing, and Copper Mining

An Interview. By T. A. Rickard

Mr. Channing, you are a Columbia man, are you not?

Yes, of the class of '83 of the School of Mines.

I was present when you received the honorary degree of Master of Science at the semi-centennial of the School of Mines in 1914. You are a New Yorker?

Yes, I was born in New York City, in 1863, and graduated from Columbia when I was 20.

What was your first job?

My first job was with Allan Stirling, the inventor of

for the firm. The principal work was that of keeping the accounts, taking orders, collecting bills, and very frequently, helping in the foundry. We used to cast the heavy shoes that were needed for the steam-stamps; these weighed about 1000 lb. apiece, and were made with a good deal of manganese and cast with a very high 'header.' The peculiar iron from which these shoes were made contracted a great deal in the process of cooling, and the loss by contraction was supplied by the melted iron from this header. In order to keep the header flow-

THE SCHOOL OF MINES BUILDING, COLUMBIA UNIVERSITY. THIS BUILDING WAS THE GIFT OF ADOLPH LEWISOHN.

the Stirling water-tube boiler, who was at that time manager of the mines of the Hudson River Ore & Iron Co. at Linlithgo, a few miles below Hindson, in New York State. My work was that of chemist and surveyor, for which I got the munificent sum of \$1.50 per day.

Did you remain long at these iron mines?

No. I remained there about three months, and then, through Professor H. S. Munroe of Columbia, I secured a position at Houghton, Michigan, as draftsman and book-keeper for the firm of S. E. Cleaves & Son, manufacturers of mining machinery.

This experience as draftsman, I expect, you found useful in your later career?

Well, to tell the truth, I didn't do very much drafting

ing, it was necessary to pump it up and down with an iron rod. This required the services of nearly every one connected with the institution, including myself. Very frequently in the evening of the casting-day, I would stand for over one-half or three-quarters of an hour with two iron rods in hand, pumping the headers of these shoes.

This gave you some useful experience?

Certainly, I obtained a good deal of practical experience regarding shop-work and mining machinery. After about a year with the firm I was taken on as an assistant to Frank Klepetko, at that time mining engineer to the Tamarack and Osceola mines of the Clark-Bigelow syndicate. The manager or agent, as he was known, was

Capt. John Daniell, one of the old-time worthies, really one of the most distinguished and progressive men that has ever operated in the Copper Country. At the time of my employment with Mr. Klepetko, the Tamarack was engaged in sinking its first shaft, and I remember that the Calumet lode was struck one Saturday night; on Sunday morning I went to the office and Capt. Daniell told me that the night before one of the drill-holes had encountered conglomerate and he had with him the sludge from this drill-hole. He proceeded to van it on a shovel, and thus produced the first copper of the Tamarack mine. I carefully saved the copper from this first vanning, and for a great number of years had it as one of my choicest possessions, but I regret to say that in the turmoil of moving from place to place it has disappeared. *In what year was that?*

That must have been in 1885. By the way, there was one little piece of work I did before going with Klepetko, and that was in the autumn of 1884 when I acted as assistant in the Copper Country for A. P. Swineford, Commissioner of Mineral Statistics; I wrote for him that portion of his report covering the copper properties. This, in itself, gave me access to all of the mines of the district.

The Tamarack workings became the deepest metal mine-workings in the world, did they not?

They did, but at the time No. 1 Tamarack shaft was sunk, cutting the lode at 2270 ft., this then deep level was considered a tremendous achievement. The No. 5 shaft eventually reached a depth of 5268 ft. vertical.

Is it likely that the Tamarack mine will be re-opened, having regard to the favorable copper market?

The Tamarack is now owned by the Calumet & Hecla Mining Co., but it is so deep that under ordinary conditions, with the low price of copper, it hardly pays to operate. I have no doubt now, with copper selling at 28 cents*, that conglomerate is being mined from it. Provision is also being made to treat the large accumulation of tailing.

By what process?

Re-grinding, water-concentration, and the new ammonia leaching process, which has been developed by C. H. Benedict. This same process is also being applied to the tailing from the old Calumet & Hecla mine itself.

Has flotation been used at Calumet?

No. Some experiments have been made upon it, but native copper doesn't lend itself easily to the process, although there is a possibility that it may be adopted for the White Pine mine on ore from the Nonesuch lode, in which native copper is found in a very finely divided form.

Do you recall any interesting incidents of your work with Mr. Klepetko?

During my stay at the Osceola, we concluded to move the stamp-mill from Portage lake, where the tailing was

filling the channel, to Torch lake. For that purpose it was necessary to construct a railroad from the mine to the mill, and to build a new mill. This was done during the summer; the mine was shut-down, and the Cornish miners put at work, much to their disgust, at grading the railroad. As it was necessary for them to shovel dirt into wheelbarrows, I remember hearing one of them say: "I'd as soon take a snake by the tail as the 'andles of a wheelbarrow." In the rock-cuts it was interesting to hear them joke about taking a "1-ft. stope off the bottom," and such similar underground phrases. I have no doubt, however, that late in the autumn when the railroad was finished, and the new mill in operation, the miners returned to their work underground with at least five years added to their lives. They went to work on the railroad thin and white, and came back increased in weight and well browned.

When did you leave Calumet?

In the autumn of 1885 I was asked by John Duncan, the assistant superintendent of the Calumet & Hecla, who, together with John Senter and several old-timers, were interested in a concession in Honduras, to visit that country and report upon their properties, and, incidentally, build a steam-boat for them on the Uluva river, so as to hold their concession. In October of that year I sailed from New Orleans on the *City of Dallas* with all the materials for a stern-wheeler steam-boat, which was to draw 2½ ft. of water, and a crew of boat-builders. We arrived at Puerto Cortez, and after starting the men at work on the boat, I made my first trip into the interior. The narrow-gauge railroad was running from Puerto Cortez to San Pedro, and from there the trip was made on mule-back. The results of my investigation of the placer deposit were disappointing; the quartz veins were so far from transportation that it was impossible at that time to exploit them profitably; the mahogany concessions proved to be mythical forests; and the amount of freight on the river was not sufficient to keep the boat in commission. I returned in May 1886 to Calumet, and at a meeting of the directors of the company they told me the only fault they had to find with me was that they had not sent me down about a year earlier.

What did you do then?

The new Gogebie range was then opening up, and these same people were interested in options in that district. They sent me over to take charge of them, and I landed in Bessemer, Michigan, in May 1886, when that town was just being carved out of the wilderness, and the streets were axle-deep in mud. Some of the prospecting was unsuccessful, but I succeeded in striking the first ore upon what was later known as the Mikado mine. On the Gogebie it was my good fortune to meet and become associated with another Cornishman, who was as good a friend and advisor to me as was John Daniell; this man was Joseph Sellwood, at that time manager of the Colby mine. I think that Joseph Sellwood was probably as progressive in the Iron Country as John Daniell had been in the Copper Country, and I have always felt that

*The date of the interview is indicated by this quotation for copper.

my career was very much influenced by the good practical advice I got from these two Cornishmen.

I am glad to hear you say that. It does seem to me that the combination of the hereditary mining sagacity of the Cornishman added to the technical education that Columbia gives ought to fit a man for doing the work of mining. What next?

In 1887 Michigan passed her first mine-inspection law, which provided for county mine-inspectors, and I was chosen for the position in Gogebie county. I look back now and consider that I must have had a great deal of assurance to accept a position of such responsibility, considering my limited experience. However, I got as many of the English publications as I could on mine accidents and their prevention, and the reports of Her Majesty's inspectors, and I believe that for the three years that I

ing mining themselves or having their sons educated in mining. Technically-educated mining engineers in the Lake Superior region were then few and far between. I wrote a letter to the *Marquette Mining Journal* on this subject and this was seen by J. A. Hubbell, then a member of the State legislature. He spoke to me on the matter and proceeded to get the first appropriation of \$50,000 for what is now the Michigan College of Mines at Houghton.

What was your next appointment?

In March 1890 I resigned as Mine Inspector and was made superintendent of the East New York iron mine at Ishpeming. At that time, and also for the last year that I was on the Gogebie range, I did considerable underground work for Messrs. R. D. Irving and C. R. Van Hise, who wrote the now famous Penokee-Gogebie mono-

THE STEAM-STAMP AS USED TO CRUSH NATIVE-COPPER ORE AT THE CALUMET & HECLA.

graphed the position. I did it with benefit to both the miners and the operators.

Your work as an inspector must have given you a good opportunity to gain insight into the character of those operating mines, both above and underground.

It did; not only in my own district but in that of the other districts, for we mine inspectors exchanged visits. I think that probably more than anything else my position gave me an opportunity to learn the point of view of the laborer himself, so that in later years, when I was put in positions of responsibility, I felt that I could look upon the question from both sides.

You became interested in mining education, did you not?

During my term as Commissioner of Mineral Statistics I had an opportunity of talking with a great many of the miners, and numbers of them expressed to me the wish that they might have some opportunity of either study-

graph, which was the first American work actually describing the formation of an ore deposit. In 1893 I took charge of a series of explorations for iron ore in northern Michigan; these were conducted by the Chicago, Milwaukee & St. Paul Railway Co. Most of this was in new districts, and while the commercial results amounted to nothing, a great deal of pioneer work was done which, in later years, has been of inestimable value to that portion of the State.

When did you go to the Calumet & Hecla?

In the autumn of 1894 I accepted the position of assistant to S. B. Whiting, who was then the general manager for the Calumet & Hecla Mining Co. I took this position with considerable misgiving, as it was notorious that the Calumet & Hecla mine was an Augean stable, and the task of cleaning it was Herculean. I was young and impulsive and tried to do too much in too short a time;

the consequence was that about the middle of the next year I was summarily dismissed, and I thought that my career was at an end. On the way toward Chicago I stopped at Iron Mountain and spent a day with my old friend, James MacNaughton; he was then the superintendent of the Chapin iron mine. Mr. MacNaughton was born at Calumet and knew the Calumet & Hecla mine well. He encouraged me; told me not to despair; he knew that I was right; that it was not my fault that I had been discharged. A few years later Mr. MacNaughton himself was made manager of the Calumet & Hecla, when the situation, on account of high cost and inefficient work, had become most precarious. With a ripper experience than mine, because of his successful management of the large Chapin mine, with his knowledge of the people at Calumet, with the further advantage of being a native-born son, he made the Calumet & Hecla what it is today. I remember his writing me a letter after he had been there six months, in which he said: "Channing, yesterday I gave the tree a gentle push and 500 rotten apples fell off; what will happen to it when I give it a real shake, you can imagine." By this he meant that 500 unnecessary employees had been let out. I am probably violating no confidence by saying that at the time I went to Calumet the cost per ton of 'rock' treated was about \$3.80; at the time Mr. MacNaughton had taken hold, it reached \$4.50, and under his régime the cost, in a few years, was reduced to \$2.25. I remember that when I went to Calumet I found them laboriously dumping timber into the skips, sending them down to the various levels, and then pulling them out, one at a time. I designed a timber-car, something like a flat car, which could be hitched to the rear of the skip. It had stakes on the sides and carried about 100 pieces of timber. It was no trick to hitch one of these onto the skip, lower it to the level, and dump off the timber, but the old crowd at the mine decided that inventions of this kind were not to be desired and so my skips were relegated to the boneyard. After MacNaughton took over the property, he saw these cars one day and asked what they were, and was told they were the "Channing timber-cars." He said they looked good to him, put them on, and they have been in use ever since. This simply shows the old-time reactionary spirit against which Mr. MacNaughton and myself had to fight.

Were you not, Mr. Channing, later employed by the Calumet & Hecla company to do some special work?

Yes. In 1910 the Calumet & Hecla, which had acquired interests in 11 other Lake Superior copper properties proposed a consolidation of the 12. It was necessary to have some independent engineer make a report as to the relative value of the properties for this consolidation, and so, 17 years after I had been dismissed from the employ of the company, I was selected to do this work for them. Unfortunately, there was sufficient opposition to the consolidation to prevent its becoming an accomplished fact, but I, on my part, felt that the company had more than redeemed any reflection which it might have cast upon me in 1893.

So that was your first real set-back. What followed?

As I said, I left Calumet heart-broken, returned to New York, and found nothing to do. I had some money, and so instead of moping in an office, I spent my time in traveling through the various mining districts, seeing what I could see, making notes, and occasionally getting the job of a mine-examination. During the summer of 1895 I helped Professor Peele of Columbia with his summer school of mining in Gilpin county, Colorado, at which time I had the pleasure of first forming your acquaintance, Mr. Editor, and also, incidentally, of meeting F. C. Alsdorf, who afterward brought to me the undeveloped property which is now the Miami mine. In the summer of 1896 I helped Professor Peele again with his mining school, this time at Butte. There I again met Mr. Klepetko, who was manager of the Boston & Montana. He had just finished and was operating the then new reduction works at Great Falls. I became his assistant, and my thanks are due to him for whatever knowledge of practical metallurgy I have acquired. I remained with him for nearly a year and in '97 returned to New York, and did my first consulting work for the old firm of Lewisohn Bros.

And you have been connected with them ever since, I believe?

Yes, for 19 years now. One of the first examinations I made for them was in Arizona, in 1897, when, as a matter of curiosity, I visited the Clifton-Morenci district, where I saw the first 'porphyry copper' mining in the United States. James Colquhoun was then in charge of the Arizona Copper Co. and was sending down the incline to his concentrator ore that looked more like burned lime, with occasional specks and veins of black in it, this being the chalcocite. The three days that I spent in this locality impressed upon me the fact that huge masses of such low-grade material (and in those days we called 3% ore 'low-grade') could be made of commercial value. It was either on this trip or the succeeding one that Lewisohn Bros. had me examine the Highland Boy mine, at Bingham. It was owned by the Utah Consolidated Copper Co., and had been floated in London by Samuel Newhouse at 7s. per share. The mine had been started as a gold mine, using the cyanide process, but the large amount of copper in the ore seriously interfered with cyanidation. In driving one of the lower adits to develop the mine, which at that time showed only oxidized ore, they encountered a large body of sulphide copper ore. Shipments were running as high as 18% copper, with large values in gold and silver. At the time of my visit quite an area of ground was opened up on No. 5 adit, the average of my samples being something over 7% copper. At the time the idea of secondary enrichment was vaguely known, and while I recognized that undoubtedly some of this copper was secondary, yet I could see that enough of it was primary to warrant me in assuming reasonable persistence in depth. Lewisohn Bros. had an option on a large block of shares that had not long to run, and my first examination of the mine

simply occupied some two or three hours. I took no samples, but immediately returned to Salt Lake City and sent them a message in code that it was the best copper mine I had seen for a long time, and for them to be careful under no conditions to let their option lapse. I then

Lewisohn Bros. to drill the properties, and during the summer of 1898 this work was done, with Louis D. Huntington in direct charge of the drilling. The result showed that the ore did not run 3%, but only a trifle over 2½%, and as the price of copper was low, the Lewisohn Bros. abandoned the operation.

But that, I believe, did not end the episode?

No; in the latter part of the next year the late Leonard Lewisohn, who certainly was a man of great sagacity, saw that the turn had come, that the price of copper was to advance, and after consulting with me as to the possible cost of treatment, took over the properties at Ducktown and organized the Tennessee Copper Co., taking in the Polk County mine, the Burra-Burra mine, and the London mine. The shaft on the Polk County mine was deepened, and two new shafts were started upon the other two. A railroad was built, a roast-yard graded, and a smelter erected on the Ocoee river at what is now known as Copperhill station on the Louisville & Nashville railroad. Predictions were made that it would be impossible to mine and treat this ore at a profit, but I felt that by combining Lake Superior methods of mining with Montana methods of smelting, copper could be produced at 10 cents per pound. The smelter was started in August 1901, my predictions of costs were fulfilled, and the property has been a producer ever since. *You became president of the company, did you not?*

returned to the mine the next day, and took my leisure in sampling and making my formal report.

Apparently, Mr. Channing, you believe that a correct impression of the character of a copper mine can be obtained by a mere visit?

In a great many cases a man of experience will be able to pass a quick judgment on a copper mine without the necessity of laborious sampling and assaying. The Lewisohn Bros. took up their option, furnished the money for the building of a smelter, which was done under the supervision of Frank Klepetko. The mine became a large producer, and I am sorry to say that the stock was sky-rocketed from 7s. to £14, a price, however, never warranted by the condition of the mine. It was acquired subsequently by A. C. Burrage, under circumstances that were graphically, though not altogether truthfully, exploited by Thomas W. Lawson in his articles on 'Frenzied Finance.' *When did you go to Tennessee?*

In 1898 an English corporation, the Ducktown Copper, Sulphur & Iron Co. was operating the Mary mine at Ducktown, Tennessee. P. de P. Ricketts acted as their consulting engineer, and called their attention to the fact that there were several other mines in the district that it was desirable for them to add to their holdings. They stated that they had quite sufficient holdings, so Dr. Ricketts took up these options and submitted them to Lewisohn Bros. He expressed the opinion that the ore would run 3% in copper. I was delegated by the

MAP OF PART OF TENNESSEE.

ONE OF THE CALUMET & HECLA SMELTERS.

On the death of Leonard Lewisohn I became president of the company and remained so for five years.

Do you think it is judicious for the mining engineer of an enterprise to be also president of it? In other words, to what extent do you think it is prudent for an engineer to be intimately concerned in the formulation of a company's policy?

I think that the engineer, if he has business ability, should be put in direct charge of the operations of the property, and should be responsible for its outcome. It is seldom, however, that we can find "the admirable Crichton" who is a mining engineer, a business-man, an

executive, and a financial genius, but if he is a good mining engineer, a good executive, and a good business manager, then, if he is associated with good financiers, I know of no better combination.

What were your methods of smelting at Copperhill?

I was seriously tempted to begin with pyrite smelting. First, I consulted my good friend, Klepetko; he communicated with Robert Sticht; they both advised me that on a new property it was not desirable to make too many innovations, so we fortunately started with a method of smelting heap-roasted ore in blast-furnaces. After we had been running about a couple of years, W. H. Freeland, then manager of the Ducktown Copper, Sulphur & Iron Co., and now a resident of San Rafael, in your State, began the experiment of treating his ore pyritically. He froze furnace after furnace, tried hot blast and cold blast, and finally, after a year's patient experimenting, succeeded in smelting the ore successfully by the heat of its own combustion, with the addition of barren quartz and a very small amount of coke. He soon changed from roasted-ore smelting to pyrite smelting. I was glad to profit by his experience and follow in his wake. We altered the Tennessee plant so as to perform pyrite-smelting without making any changes whatever in the furnace.

Was that when the smoke troubles began?

Yes, the farmers of Georgia began to protest, the boundary of that State being only about 1000 ft. away, and the prevailing wind being from the north, it blew the smoke from the smelter in Tennessee across the boundary into Georgia. I had always felt, even from the very beginning, that there were possibilities of utilizing the sulphur of the Ducktown ores, so we started experimenting by closing up the top of the furnace, preventing the entrance of 'false air' as it is called, and started making sulphur di-oxide determinations of the gases. Much to our surprise, they ran 6% and upward. The question then arose, should we use the 'chamber' process or the newer 'contact' process. We got into communication with the Badischer Anilin und Soda Fabrik, in Germany, who sent over a corps of engineers and chemists to investigate our conditions. They were very frank in their report, and told us that our gas was so rich that it was unnecessary for us to consider their contact process, and that we would be perfectly safe in using the old-fashioned chamber process. On the strength of my recommendations the directors of our company authorized an expenditure of \$1,000,000 for the building of a sulphuric-acid plant. I called into consultation the late F. J. Falding, and between the two of us the plant was started and put into operation. We soon started making 60° B. acid, but, of course, in a new process of this kind, ran against innumerable difficulties in the way of eliminating fine-dust, and in getting the proper nitration. We succeeded, however, in getting the plant up to a capacity of 300 tons of acid per day.

To whom did you sell the acid?

To fertilizer manufacturers in Georgia and neighbor-

ing regions. A little later we made a contract with a new concern known as the International Agricultural Co. for all of our product. Later still the Lewisohn Bros. sold out, the enterprise passing into other hands. This was in 1908. Utley Wedge then took up the work where I left it. He has made many improvements, and is at present producing concentrated acid and has also doubled the size of the plant. The plant that I built has now been keyed up to a production of 600 tons of acid per day, and presumably in a year, the Tennessee Copper Co. will be producing 1200 tons of 60° acid per day from fume that ten years ago was not only a waste, but a nuisance.

Of course, the War has created an abnormal demand for acid?

It has, and, of course, it takes time to build acid plants, which is the reason that the Tennessee Copper Co. has such a good market for its concentrated acid today.

When you left the Tennessee Copper Co., Mr. Channing, if I remember correctly, you formed the General Development Co.

That's not exactly right. We formed the General Development Co. in 1906, some three years before I gave up the active management of the Tennessee Copper Co. The General Development Co. was organized for the purpose of developing prospects and taking hold of partly developed mines, with a capitalization of \$2,500,000, later increased to \$3,000,000, of which only \$1,000,000 was paid in cash. Up to date it has paid about \$1,800,000 in cash dividends and has assets of a value of practically \$5,000,000. What led to the formation of this company was that in 1904 Messrs. Requa, Bradley, and McKenzie had developed a very promising copper prospect near Ely, Nevada, this being one of the first so-called porphyry deposits, that is, a low-grade mass of silicious rock in which chalcocite is sparingly disseminated. In the winter of 1904 they were ready to raise the necessary money to develop and equip the property, build a railroad, and erect reduction works. The raising of this money was entrusted to a large banking-house in New York whose senior partner assured them that he would have no difficulty in obtaining the necessary funds in France. He went to Paris, with most excellent detailed reports by Requa, Bradley, and MacKenzie, but when he confronted the French engineers with the proposition of making money from a deposit that ran 23% copper, they laughed at him, and refused to consider it. It simply showed that they were not up-to-date, for they did not realize what could be done. So, in the summer of 1905, I was asked by the firm of S. D. Loring & Co., of Boston, to make an examination and report upon the property of the Nevada Consolidated Copper Co. It was here that my three days spent at Clifton, Arizona, in 1897 were of incalculable value to me, for I saw that with Lake Superior methods of mining and Arizona Copper Company methods of concentrating, plus the smelting practice of the Boston-Montana and the Utah Con-

THE MIAMI MINE AND MILL IN ARIZONA.

solidated, the property would be a successful venture. On the strength of my report, Messrs. Hayden, Stone & Co. and other people took stock, I believe, in the neighborhood of \$4 per share. A block of these shares was offered to Adolph Lewisohn, who declined to take them. Later on, seeing the shares advance, he approached me and suggested the organization of the General Development Co., with myself as consulting engineer.

When did you find the Miami?

After the General Development Co. was started, we spent considerable money at Butte and other places without result, but in December of 1906, when visiting Globe, I ran across my friend, F. C. Alsdorf, whom I had met in Gilpin county, Colorado, in 1895. He called my attention to some ground six miles west of Globe, which,

in his experience of the Clifton district, he thought might be underlain by a copper deposit. I went over the ground with him, and looking at it in the light of my Clifton experience, and of experience with the Nevada Consolidated at Ely, I agreed with him. The General Development Co. took over the property and began development work in January 1907, and in May struck ore, at the No. 2 Red Rock shaft, at a depth of 220 feet.

What was the ore?

The copper was in the form of chalcocite, disseminated through schist, and ran about 3% copper. Although the Miami and Ray mines are both in schist, still the term 'porphyry' has become so well established that the name is used notwithstanding that in some cases the ore is in real porphyry, and in some cases in schist. The

THE TENNESSEE COPPER SMELTER, AT COPPERHILL, TENNESSEE.

Miami Copper Co. was floated in the spring of 1908 at \$5 per share, the company being organized for 600,000 shares. Of these 300,000 were issued for the property to the General Development Co. and the first 200,000 were sold at \$5 per share to provide initial working capital. Later, as the mine developed and the ore reserves increased, the remaining 100,000 shares were sold at \$10 per share. Afterward the capital was increased; and 150,000 shares were issued at about \$17 per share; it consists now of approximately 750,000 shares issued, and the total initial cash invested in development and equipment amounts to \$4,500,000, so that the original purchase price becomes relatively insignificant as compared with the cost of development and equipment.

So the price of the property was small compared with the cost of making it a mine?

No, that is not exactly right. If you consider the bare cost of this undeveloped property to the General Development Co., then Yes. The General Development Co. took the risk of prospecting and had lost money in previous ventures leading up to this one, but it sold the developed Miami property to the Miami Copper Co. for, at that time, a consideration that was \$1,500,000, namely, 300,000 shares at \$5 per share.

This venture has proved a complete success?

It has. The Miami Copper Co. is now producing over 4,500,000 lb. of copper per month at a cost of under 9 cents per pound, and it is estimated that it has ample ore resources to maintain this output for many years.

Mr. Channing, I believe your company is a defendant in a case brought by the Minerals Separations for infringement of patent rights governing the oil-flotation process.

Yes, this is a fact. The case was tried in the spring of 1915 in the U. S. Circuit Court at Wilmington, Delaware. No decision has as yet been rendered.

I take it that you are impressed with the great usefulness of the flotation process?

Yes, I am, but in view of the fact that the matter is in Court, I do not care to discuss it.

You consider mining engineering a good profession for the American boy?

I do, but I doubt whether the possible prizes are as great as they were at the time that I graduated. Still, the tendency at present is to demand more and more that technical graduates be employed at the mines, even in such subordinate position as shift-bosses, so that there always is an opportunity for a capable man to start at the bottom and work his way up. I have tried, year after year, to impress upon the graduates of mining schools that they must not think that when they get their degree they are finished engineers. They must realize that they have only the ground-work for learning the business of mining and that it is as necessary to work in the mine or reduction works to learn the business of mining as it is to work in a grocery store to learn the grocery business, or in a bank to learn banking.

Then I shall ask you whether you agree with me in considering that the American mining engineer as a rule does not get enough underground experience; in other words, that he shines most at surface, and appears to have a dislike of work underground?

No, I would not say so. I think the younger graduates who are coming out are just as ready to go underground as they are to go into the mill or smelter, and there have been such refinements in milling and smelting that the great economies of the last ten years and probably for many years to come are going to be in mining methods; there's where the great improvement is to be achieved.

What prospects can you see for the acquirement of additional skill in the finding of ore, which is, after all, the first step in mining?

The easily recognizable metal deposits of the United States probably have all been discovered. There undoubtedly remain a great many, not only of copper, but of other metals, in which a careful study of the surface conditions is required in order to lead to correct inferences. Take, for example, the question of oil. I was impressed, some four years ago, on my visit to Russia, to find that there was little 'wild-catting' or venturesome prospecting in Russia, such as there is in the United States. If there was any supposition that a certain district contained oil, possibly a year or six months was spent by trained geologists in thoroughly studying the geology, in putting down short drill-holes to determine the formation, to establish the dome or the anticline, and not until all this work had been done carefully was the first deep drill-hole started. The result has been that in Russia there are probably fewer dry holes than in the United States.

In other words, careful scientific investigation is recognized now as a first step in intelligent mining?

It is. The days of the rich deposit that anyone could exploit are over, and we are reduced to the necessity of extracting our metals from material that in the past was passed over as waste rock. To make material of this kind pay one must have a large deposit and careful geological work must be done in connection with its development. The method of mining and the method of treatment to be adopted must be the subjects of careful study and experimentation, and after the work is under way one cannot let well enough alone but must be ever on the alert to improve extraction and reduce costs.

FINELY POWDERED ALUMINUM forms a part of two of the most destructive explosives known, one of which, ammonal, is a mixture of five to eight parts of ammonium nitrate with one part of aluminum powder and is used to charge shells. It is one of the few explosives which presumably can never be used as a propellant, as its action is so sudden and the force so tremendous that no gun would be able to stand it.

GOLD OUTPUT of the Rand in August was 781,000 oz. fine, an increase of 20,000 oz. over that in July.

Future Development of the Flotation Process

By Rudolf Gahl

*The flotation process is in its infancy. For this reason the Inspiration concentrator must be necessarily in the first stages of its development. In what direction future changes may take place, is perhaps indicated by tests which have been made partly on a laboratory scale and partly on a somewhat larger scale, but which have not yet been incorporated into our regular milling process. Of these latest developments, I will try to give an outline in the following:

THE POROUS BOTTOM is, as one may imagine, the most essential part of a pneumatic-flotation machine. Our experience with the porous bottoms of the different constructions brought out clearly the principal difficulty attached to them, which is, that the pores have a tendency to contract gradually and thereby to retard the passage of air through them. This tendency was more pronounced in the solid porous bottoms employed in the Flinn-Towne flotation machine than it was, for instance, in those of the Callow type, although the latter also show a tendency in this direction. Our first supposition was that the choking was due to the fact that the air entering below the blankets carried particles of dust, which would settle in the fine pores and reduce their area. Indeed, a canvas blanket will, after a certain length of service as a porous medium, always show some ring-shaped spots of dark color opposite the air-inlets, clearly indicating that a deposition of dust particles on the blanket actually does take place. To make sure of this point we cut out round disks from a Callow blanket that had been used for some time, and investigated their porosity by using them as porous bottoms in a glass tube standing in a vertical position. Air under pressure could be applied to an air-chamber fixed underneath these disks, and the air passing through the porous blankets could be measured by a gas-meter. The quantity of air discharged through the porous medium offers a measure of the porosity of the blanket, and for this reason, the velocity or speed with which the counter of the gas-meter revolves, gives an indication of the porosity of the porous disks being tested. To our surprise, we found that the darkest points of the blanket were not those of lowest porosity. On the contrary, the points farthest away from the air-inlet showed the greatest tendency to choke. An explanation of this paradoxical behavior seems to be offered by the fact that an air blanket is kept in a state of more or less agitation near the air-inlet (in the Callow machine this happens to be a point remote from the places where it is held rigid) while farthest away from this point the

blanket assumes a state of comparative rest. Incrustations, due perhaps to the presence of soluble salts in the water in conjunction with fine slime, always form to a greater or less extent in the top layer of the blanket. Evidently, the agitation counteracts the formation of the incrustation, while there is no such influence in the portions that are essentially at rest. For this reason, we concluded that a solid porous material is not suitable as a diaphragm in a flotation machine of the pneumatic type, if a bottom of long life is required. As a matter of fact, the experience of everybody who experimented with solid bottoms seems to have pointed in the same direction. Mr. Cole for a while tried carborundum tubes in his machine. We tried carborundum stones in the flotation machine of the Inspiration type and abandoned them, and I believe that even Messrs. Flinn and Towne have, in the meantime, given up the solid bottom of their original design.

A necessary condition for a serviceable flotation-bottom appears, therefore, that the porous medium be of a flexible nature. The 4-ply canvas stitched every half-inch or so, which Mr. Callow's first cells contained and which we have used for considerable time in the Inspiration machines, seems to answer this purpose fairly well. We find, however, that to keep it in good working condition and prevent incrustations from forming on the top, we have to clean it frequently. This is done by dipping an iron pipe connected with a water-hose into the compartments and sweeping the canvas bottom with the jet of water discharging from the lower end of the pipe. The canvas blankets seem to last for about 6 months at the most. As they are inexpensive, the replacing of a bottom after that time is not a serious item in the operating costs. The giving out of the canvas is due to the wear caused by the frequent cleaning. The top layer wears out first, the holes created by the stitching forming nuclei for the formation of larger holes. By the time the top layer has a number of holes the canvas blanket is generally discarded. In the interest of greater economy, we intend giving up inter-stitching the layers of canvas. We are trying to decide whether it is better to use single sheets of thicker fabric or to use canvas similar to the kind that we have been using and to put several layers on top of one another without inter-stitching them. The latter has the advantage of requiring the discarding of only one layer, when it becomes defective.

There will always be some tendency to form incrustations so long as canvas is used for flotation mediums. Their formation will be entirely prevented only by substituting an altogether different material. We have made experiments in this direction. One of my former

*Abstract from 'History of the Flotation Process at Inspiration,' a paper presented at the Arizona (September 1916) meeting of the American Institute of Mining Engineers.

assistants. R. H. Haskel, deserves credit for suggesting them. For instance, we substituted for the canvas blankets, thin rubber sheets perforated with a multitude of needle-holes and obtained an excellent froth. The objection to their use is that their life is limited. When sheets of rubber of an increased thickness are used, the needle-holes require too much pressure to form openings of sufficient size for the passage of air, and to make a thick rubber sheet suitable for this purpose, slits several millimetres long have to be substituted for needle-holes. We have had one or two rubber bottoms of this design in operation, but, just at present we are not ready to substitute them for canvas blankets. We also tried a blanket made from a material that goes under the name of sponge-rubber and can be produced with rather fine texture. We have not been able, however, to obtain lastingly good results from the use of this medium. Furthermore, we tried a woven fabric containing rubber threads in one direction and threads of cotton or the like in the other direction and a rubberized canvas made by the Goodrich Rubber Co. We are not prepared to use any of these materials on an operating scale.

The advantage of rubber should be, in the first place, that on account of its smoothness it would have less tendency than canvas to permit the formation of incrustations. Besides, an elastic medium should have the additional advantage of avoiding the danger of catching small sand or slime particles in the pores of the medium, as an expansion of the medium (which may be effected, for instance, by increasing the pressure) would widen the pores and remove such particles. We think that our experimental work in this direction is encouraging.

THE RECOVERY that it is possible to effect in a flotation plant depends largely on the grade of concentrate desired. With a low grade of concentrate, a low tailing can be made, but when a high grade of concentrate is stipulated, increased tailing-losses cannot be avoided. A question that suggests itself in this connection, and which we have tried to answer by laboratory experiments is, "How can we raise the grade of our concentrate—that is, reduce the percentage of insoluble matter contained—without entailing additional copper losses?" We know from laboratory experiments that this can be done by expensive methods—for instance, by heating the solutions—but such a procedure would be undesirable from an economical standpoint. Experience has shown us that concentrate produced in the first compartments of the cleaner-cells is always freer from insoluble matter than the concentrate produced in the last compartments. The problem then resolves itself into finding a suitable cleaning process for the concentrate from the last compartments of the cleaning-cells. By treating this low-grade concentrate hot, with the addition of caustic soda, we have been able to separate it into a high-grade concentrate and a fairly low tailing. This method necessitates only the expense of heating a small fraction of the pulp and may be a commercial possibility.

CARBONATES. Another subject on which we have spent considerable time in our laboratory is the problem of re-

covering copper carbonates by flotation. When we started our flotation plant, we discovered, to our astonishment, that the machines not only saved a high percentage of copper sulphide but that they also recovered some of the carbonates. Ever since that time, we have tried to find means of improving the carbonate recovery.

In the first place, we studied all of the oils that seemed to have a tendency to cause the flotation of such minerals. Later on, we tried other means in addition to the variations of the oils. One way in which copper carbonates and similar minerals might be recovered was outlined by Alfred Schwartz in his U. S. patent No. 807,501. The process consists in first artificially producing a sulphide coating on such oxidized minerals by the introduction into the pulp of soluble sulphides, and then adding suitable 'oils' and effecting the flotation. If it were possible to thus chemically produce coatings of sulphide identical with the surface of the minerals formed by nature, this process would work well, as evidently the nature of the surface is the only characteristic that determines whether a mineral will float or not.

Minerals Separation owns a number of patents covering this subject. Their English patent No. 26,019, issued to Sulman & Picard, describes the flotation of oxide copper minerals by similar means.

I am not aware that equivalent patents have been issued in the United States. The English patent in question is of a later date than the Schwartz patent above mentioned. The representatives of Minerals Separation have experimented with this system, while demonstrating their machine to the Inspiration company. As far as I know, they have not proved its practicability. In the course of their experiments, they tried the application of sodium sulphide and sodium polysulphide for this purpose. The latter was produced by treating sulphur with hot caustic soda. At the time these experiments were made, I was not familiar with the chemical action taking place, which, as much as I know now, actually results in the formation of polysulphide mixed with thio-sulphates and other oxygen-sulphur compounds. The failure of their experiments, I ascribed to the fact that perhaps a polysulphide which they were anxious to make was not actually produced. I proceeded to make sodium polysulphide by the treatment of sodium sulphide solution with sulphur powder. When we applied this reagent to some of our carbonate ores in laboratory flotation experiments, we noted that a good recovery was obtained. The composition of the compound was varied in order to find just what composition gives the best results in the flotation of carbonates. Our experience seems to indicate that sodium sulphide alone encourages the flotation of carbonates, but that sodium polysulphide, or sodium sulphide containing more sulphur than would correspond to the chemical formula Na_2S gives better results. The addition of caustic soda to the sodium polysulphide was found beneficial.

The question then arose as to why we succeeded in effecting the flotation of oxidized copper when the experiments of the members of the Minerals Separation

staff failed. Tests along these lines brought out the fact that the Minerals Separation compound when applied to our carbonate ores also worked successfully, but that it did not on our regular milling ore. Our own compound when added to our mill-ore mixture increased the recovery of the carbonates, but evidently interfered with the sulphide extraction, and for this reason seemed to be of as little use as the compound of the Minerals Separation Company. When applying reagents of this character to tailings resulting from ordinary flotation treatment, with a view to effecting a sufficient sulphide extraction by the regular flotation process, and using the compound in question only for the purpose of increasing the carbonate extraction, we have found so far that the increase in copper-carbonate recovery over the one obtained without the addition of such chemical compounds is not worth the additional expense.

But this is only a consequence of the fact that carbonates exist in very small amounts only in our mill-ore and are partly saved by the ordinary flotation process.

There is no real difficulty about saving carbonates by the method mentioned if they exist in quantities that make it worth while to save them. That copper carbonates can be recovered may easily be demonstrated by treating a deslimed feed in a series-flotation machine. If at the point of the machine, where the sulphide recovery is nearly finished, sodium sulphide is added, the decidedly green color of the concentrates in the following compartments leaves no doubt on this point. The desliming of feed seems to assist the carbonate recovery.

It would be well to establish why sodium sulphide and polysulphide tend to increase the recovery of copper carbonates. A coating that might be expected to form cannot be detected. The concentrate resulting from the treatment of pure carbonate ore is decidedly green; besides, when an alkaline condition of the pulp is used there is very little, if any, tendency for any sulphide coating to form, and the alkaline state of the pulp is (as explained above) exactly the condition under which the best carbonate extraction results. Another fact that seems to contradict the explanation of these results by the assumption of a sulphide coating is, that when we proceeded exactly as suggested by Schwartz—namely, when the application of soluble sulphide was followed by the addition of flotation agents and by the actual flotation—we seemed to obtain poorer results than when the procedure was reversed by applying the oil first and following with the application of some soluble sulphide, although the latter method would certainly seem less favorable to the formation of a sulphide coating, and perhaps for this reason has not been suggested by Schwartz.

Another theory that has been mentioned as an explanation of this phenomenon is that colloidal sulphur is formed by the solution of sodium polysulphide in water, which, as is known, is a good flotation agent. For instance, it is pointed out in the U. S. patent No. 1,140,865 taken out by R. F. Bacon of the Mellon Institute in Pittsburgh, that by setting free colloidal sulphur, say, by the reaction of a soluble sulphide with sulphur dioxide, good

flotation results may be obtained as far as sulphides are concerned. To make the process available for the flotation of carbonates and other oxidized copper minerals, he suggests that a sulphide coating be first formed on the minerals, that is, to follow Schwartz's idea. Whether the colloidal sulphur by itself has a beneficial influence on the recovery of the carbonate (as has been suggested in explanation of our observations) seems rather doubtful when it is considered that we have obtained good results in alkaline solutions in which colloidal sulphur does not seem to separate out from polysulphide containing only a limited amount of sulphur such as was used in our tests. The full theoretical explanation of these facts must therefore be left to future investigations.

SILICATES. In our experiments with the object of saving the oxidized copper minerals, we soon found that we could save some of these minerals, while others were entirely refractory to the method above mentioned. To establish which minerals could be saved and which not, we attempted an analytical separation into carbonates and silicates. The chemical methods which we tried for the purpose of distinguishing between the two proved unreliable, however, and we had to resort to the separation by specific gravity (panning). The carbonates of copper (malachite and azurite) are heavier than gangue, and the silicate (chrysocolla) is lighter. The separation is rather difficult, owing to the small difference in specific gravity, and the results are therefore far from being altogether reliable, but they seem accurate enough to indicate that the method of saving carbonate copper above referred to is of value only for the recovery of carbonates and does not apply to silicates. This fact seems to be another corroboration of the assumption made above, that carbonates of copper do not float simply because of the formation of a thin surface coating of copper sulphide. It can easily be verified in the laboratory that silicates can be coated with copper sulphide fully as easily as copper carbonates. For this reason, if the filming theory is right, it should be possible to float silicates just as well as carbonates. There is no doubt that they can be floated by transformation into sulphides, only this transformation must not be confined to the surface, but must go deeper. Our experience is, that to effect a good recovery, it is necessary to acidify the pulp so strongly that practically all the silicate of copper is dissolved and by the action of hydrogen sulphide or other soluble sulphides is transformed into the state of chemically-precipitated copper sulphide. In this form there is no difficulty about the recovery of the copper by flotation, but this procedure is not entirely without objection.

In case hydrogen sulphide gas is used, the acid combined with copper is regenerated. This tends toward a low acid consumption and a good copper extraction, on account of the fact that the treatment winds up with a small percentage of copper in solution and free acid present, both of which are desirable in the light of the law of chemical mass action. But hydrogen sulphide is not a desirable reagent. The fact that it is a gas and

not a liquid introduces complications in the apparatus which are accentuated by the fact that it is poisonous and obnoxious otherwise.

Other soluble sulphides used in place of hydrogen sulphide will neutralize some sulphuric acid with the result that the acid consumption will be higher and the copper extraction lower than in case of hydrogen sulphide gas.

As far as acid consumption is concerned, it is pointed out that the free acid lost with the pulp may be settled in ponds and re-used. However, the re-use of acid diluted to such an extent is a more serious problem than is generally realized.

The treatment of concentrates that are colloidal, to a much greater extent than ores which mill-men have been in the habit of calling 'colloidal,' offers additional problems, which, however, may prove not to be as serious as they look.

Everything considered, I cannot see that the flotation treatment of oxidized copper ores after previously leaching them offers better prospects than straight leaching by decantation and precipitation by other methods.

GENERAL THEORY. It seems to me that an explanation of the qualities of the flotation-oils is not as difficult as it might appear. The problem only seems so complicated because the flotation qualities of an oil or an oil mixture have not been separated into their components. In fact, it requires a combination of qualities to make a successful flotation-oil. In the first place, the flotation-oil has to coat the mineral particles. That there is a tendency for the formation of such a coating can easily be seen from simple experiments. For instance, if samples of copper sulphide (chalcocite), copper carbonate (malachite) and gangue (silica) of the same screen size are spread out on watch-glasses and then moistened with a drop of creosote soon disappears through absorption by the copper sulphide, while it takes a much longer time for it to be absorbed by the copper carbonate and a still longer time with the gangue. On the other hand, when a drop of water is placed on the same minerals, it will disappear on the gangue first, later on the carbonate, and finally on the copper sulphide. This evidently proves that in a mixture of water and oil, the oil will attach itself with preference to the sulphide particles while the water will have the greater tendency to wet the gangue.

The second quality of a flotation-oil is that it has to form a stable froth. In such a case, the stability may be secured by more firmly cementing together the mineral, air, and oil. To accomplish this, oils are used which have a tendency to float finely-divided gangue particles. The action is characteristic of the heavier pine distillates like pine-tar and the lighter ones like turpentine if they are crude, unrefined products; in other words, when they contain some of the heavier distillates. I am not quite sure, however, whether the beneficial influence of oils of this group is not perhaps rather due to the fact that they remove colloidal material from the pulp and thereby improve its tendency to float minerals.

A third quality demanded of a successful oil-mixture is that it must be able to produce a sufficient volume of froth. This property is exemplified best by oils of the soluble type—creosol, pine-oil, and alcohols. It can be proved easily that when oils of this type are used, although they may be considered insoluble, the water acquires the frothing qualities of the oil. It may be demonstrated by shaking an oil of this character, with water and permitting the oil to separate out again. It will be found that the water has acquired frothing qualities by undergoing this treatment. It is even likely that the soluble portion of the oils belonging to this group is the only one that is active in this manner. The difference between the oils of group 1 and group 3 may be studied, for instance in a flotation machine of our type. It will be noted that the heavier mineral runs over the concentrate discharge largely in the first compartments forming a heavy dark froth and the heavy insoluble portions of the flotation oil-mixtures apparently go with it. Toward the tailing end of the flotation machines, most of this dark material has disappeared and the froth is lighter and of a more watery nature. The pulp, however, has not lost the quality of forming froth even after it gets to the last compartment of the flotation machines. This permits the conclusion that the frothing characteristics follow the tailing-pulp. The water settled in tanks and tailing-ponds has decided frothing qualities. Such water behaves in a similar way to certain alcoholic solutions with which we are used to associate this characteristic, for instance, beer or champagne. The experience of mills using the flotation process, that when the tailing-water is reclaimed the quantity of frothing-oil may be considerably reduced, further supports the assumption that the formation of froth is caused by water-soluble substances.

BAUXITE is the chief source of metallic aluminum. The great bulk of bauxite used comes from Arkansas, which in recent years has produced about 80% of all the bauxite mined in the United States and in 1915 produced more than 90%. Experiments have been made to produce metallic aluminum from alumina produced in making potassium sulphate from alunite. A process has been patented for extracting aluminum from kaolin or aluminum silicates in general. The clay is fused with sodium sulphate in the presence of sulphuric acid or with its equivalent of acid sodium sulphate, in such proportion as to form aluminum sulphate and free silica. The fusion product after cooling is dissolved in water, filtered, and treated with sodium fluoride. The aluminum fluoride which separates is fused with common salt and is electrolyzed.

As a result of the War there has been a rapid development of the manufacture of potassium chlorate in Japan. An over-supply of the product has now affected the market. There are about three factories, and the total output is placed at 7000 bbl. per month, which will be increased to 10,000 bbl. when extensions now projected are completed.

Reports on Mining Districts—General Suggestions

***GEOLOGY IN ITS ECONOMIC BEARING.** The writer should bear in mind that an economic report may be used by readers who are not geologists and should therefore avoid as far as possible technical words with which they are not likely to be familiar. If the use of such words is unavoidable it may be desirable to explain their meaning briefly.

Stress should be laid on those geologic facts that are of direct economic interest. Material that is chiefly of scientific or theoretic value and that has no direct bearing on the economic problems discussed may best be reserved for separate publication. If it seems desirable, for the benefit of specialists, to include such material in an economic report, it may, by paragraphing in smaller type, be kept distinct from the main text, so that it can readily be skipped by those who would not understand it.

ORDER OF TREATMENT. The order of treatment should follow the principle of first giving the reader a general idea of the subject under consideration before proceeding to detailed description—the reverse of the process by which the author usually arrives at his results. This suggestion applies not only to the whole report but also to the treatment of individual topics. Thus, before describing the geology of the ore deposits of a district, he might give a brief characterization like this: "It is an area of granite intruded by andesite, which is in turn cut by phonolite dikes," or "The deposits are narrow, vertical veins cutting granite, andesite, and phonolite and conforming in general direction with the phonolite dikes." In this way the reader starts with a general idea of the subject and is able to see the bearing of the facts observed and presented by the author.

SUBJECT ORDER

GENERAL ORDER. The general order treatment here recommended is applicable to a complete report on a mining district, and a paper of different scope may well follow a similar general order so far as it can be applied to the facts presented. The titles of the headings may be modified according to the varying conditions in different regions and the taste of the author, but he should have some definite plan in mind before he begins to write. The general heads may comprise the following:

Preface.	Geography.
Outline of the report.	Geology.
Introduction.	Ore deposits.

PREFACE. The preface should be written and signed by the geologist in charge of the administrative unit to which the author belongs. It should indicate the character and purpose of the investigation and call atten-

tion to important features or results set forth in the report and to their bearing on regional or other broad problems.

OUTLINE OF THE REPORT. The author should write a brief but carefully prepared abstract of the report, with a view not only of giving the reader a preliminary survey of the work but of affording an authoritative outline for the press.

INTRODUCTION. The introduction may comprise a statement of the conditions under which the work was done, acknowledgment of favors, a summary of previous work in the same field, and a bibliography, if the literature on the district discussed is sufficient to warrant it. Bibliographies are more useful if the title of each paper is followed by a brief abstract of its contents.

GEOGRAPHY. The section on geography should describe location, routes of approach, topography, climate, vegetation, and other geographic features. Relief and drainage should be described as present features of the landscape, but their genesis and evolution should be discussed under 'Geology.'

GEOLOGY. The discussion of the geology should present general geologic information with regard to the region, in the following order: (a) The character and composition of different rock formations, in order of age, commencing with the oldest and distinguishing sedimentary from igneous; (b) the distribution and structural relations of the formations; (c) metamorphism; (d) the development of topographic features with special reference to lithology and geologic structure.

ORE DEPOSITS. The description of the ore deposits as a whole and the discussion of their genesis should form the principal part of the report. In this part the subdivisions suggested below may be enlarged or condensed according to the nature of the deposits, but the general order of subjects should be preserved.

(a) History of mining development. The author may relate the successive steps in the local progress of the mining art and state the present conditions. In some reports that are essentially economic this history may follow the 'Introduction.'

(b) Production. Annual and total output of mineral products, with sources of information.

(c) General character of deposits. Fissure veins, replacement deposits, contact deposits, etc.

(d) Mineralogy. Enumeration and brief description of gangue minerals, of original metallic minerals, in order of value of metal or other distinctive feature, and of secondary minerals or products of alteration, in the same order; also paragenesis or succession of minerals and its bearing on genesis.

(e) The deposits. Distribution and geologic features, structural relations, primary deposition, underground

*Prepared originally in 1906 by S. F. Emmons; revised in June 1913 and April 1916 by F. L. Ransome. From 'Suggestions to Authors of Papers for Publication by the United States Geological Survey,' by George McLane Wood, Editor.

water, secondary deposition and alteration of ore and country rock, distribution of ore in the deposits, age of original and secondary deposits, value of ores and its dependence on geologic conditions.

(f) Genesis of the deposits. The author should recapitulate the essential facts brought out in his descriptions, show their bearing on the problem of origin, and deduce such theoretical conclusions as they may warrant.

(g) Practical applications. The author may point out how his work may aid the miners in developing their orebodies or in finding new ones and may forecast, if possible, the economic future of the district.

(h) The mines. In the detailed descriptions of the individual mines or groups of mines the general order of treatment indicated above should be followed. It is well to select one or more of the principal or characteristic mines as types to be described in considerable detail.

DEFINITIONS

The following definitions of certain terms in common use are sanctioned by the practice of the Survey, and it is desirable to adhere to them in Survey reports, as a lack of uniformity in the use of such terms is likely to cause misunderstanding.

MATERIALS

ORE. Ore is a mineral or rock from which one or more metals may be profitably extracted. Material that cannot be profitably worked today may become of economic value a year or so hence without any change in character. Consequently, in using the term 'ore' it is necessary to take into account the effect of changing economic conditions and of probable improvements in metallurgical processes. According to the definition given above it is tautologic to use the term 'pay ore.'

GANGUE. The term 'gangue' is properly applied only to the earthy or non-metallic minerals that are of common occurrence in ore deposits, such as quartz, barite, chlorite, fluorite, calcite, and dolomite. The practice of describing as gangue any metallic minerals that may happen to be of no economic value is not desirable, even if they are called metallic gangue, for it permits no uniform distinction between ore and gangue.

In describing the minerals occurring in an ore deposit it is well to distinguish the exogenous gangue minerals—those that have been brought in from some outside source—from the endogenous gangue minerals—those that are the product of alteration of the wall rock or country rock.

VEIN MATERIAL. As a collective term to describe the aggregate materials which make up the orebody, the phrase 'vein material' or 'vein stuff' may be used. 'Vein stone' is a less desirable phrase, for the reason that 'stone' is used by some mining men as a technical term for ore, whereas others make 'vein stone' synonymous with 'gangue.'

GEOGUE. Gouge is a soft, clayey material that occurs in some places as a selvage between a vein and the country rock and is usually formed by the trituration of the

country rock by motion subsequent to the formation of the vein. The term should not be loosely used for any soft, crushed material.

COUNTRY ROCK. 'Country' is the miner's term for the rock which encloses an ore deposit. The term 'country rock' has been criticized as tautologic; nevertheless, it is sanctioned by very wide usage, and its use is considered advisable where the single word 'country' might lead to confusion in the mind of the non-technical reader.

FORMS

VEIN, LODE, VEIN SYSTEM. The material filling a fissure, when not injected as molten matter to form a dike, is termed a vein. Most veins are of nearly tabular form. An ore-bearing vein is a single body of metaliferous minerals occupying or following a fissure, both walls of which generally are well defined. Where several veins are so closely spaced that the ground between them becomes in places ore bearing and in its whole width constitutes an orebody, the assemblage is called a lode, although in legal phraseology lode or lead is in a broad sense synonymous with vein. The term 'vein system' may be used for a larger group of veins and may include several lodes. The fractures of the earth's crust that admit of ore deposition are so multiform that it is not possible to give stricter definitions. Usage may differ somewhat in different districts, but the general order from simpler to more complicated deposits will be vein, lode, vein system.

SHEAR ZONE. The term 'shear zone' denotes a section of the earth's crust within which the rocks have been closely laminated by yielding to a shearing stress. It is a structural feature along which ore may be deposited, but is not itself a form of deposit.

SHEETED ZONE. Where the country rock is traversed by approximately parallel fissures separated by thin sheets of rock it is said to be 'sheeted,' and the zone affected may be called a 'sheeted zone.' In a sheeted zone the fissures are generally more widely spaced and there is less crushing than in a shear zone.

FAULT. A fault, in its simplest form, is a fracture in the rock of the earth's crust accompanied by a displacement of one side with respect to the other in a direction parallel with the fracture. A fault is not a form of orebody, but, like shear zones and sheeted zones, it may influence ore deposition or determine the shape of a deposit. There has been much diversity in the nomenclature of faults, and authors are advised to follow the terminology recommended by a committee of the Geological Society of America.¹

BEDDED DEPOSIT, BED DEPOSIT. In contrast with veins, which cut across the bedding of the enclosing rocks, some deposits conform with the stratification. Such deposits are frequently called bedded deposits, but this name suggests that they were laid down as members

¹Reid, H. E., and others. Report of the Committee on the Nomenclature of Faults. Geol. Soc. American Bull., Vol. 24, pp. 163-186, 1913.

of the stratigraphic series in which they occur—that is, that they are syngenetic deposits. The term 'bed deposit' is of broader application; it will cover such deposits as may have been subsequently introduced between the beds—that is, epigenetic deposits.

GASH VEIN. The term 'gash vein' has been employed to describe a vein that fills joints or fissures in limestone in the lead deposits of the Mississippi Valley region. A gash vein does not extend beyond a single bed or similar rock mass.

TRUE VEIN. Whitney² used the expression 'true or fissure veins' in his tabular classification of ore deposits to distinguish from gash veins those veins which, according to him, "may be presumed to extend for an indefinite distance downward." Although in his text he uses the term 'true vein,' the expression he employs in his widely quoted table has probably given currency among miners to the term 'fissure vein' or even 'true fissure vein.' 'True vein' was the term in use before Whitney's table was published, and by the earlier writers on ore deposition it was employed to indicate an orebody that filled a fissure; hence the term 'fissure vein' is in a strict sense pleonastic and should not be used in classification.

STRUCTURE OF VEIN MATERIAL. The following forms of structure may be recognized in the material filling a fissure:

1. Banded structure, in which the vein shows in cross-section a banding nearly parallel to the wall. This may be subdivided, according to origin, into—

(a) Banded structure by filling, in which the filling is evidently a series of layers of vein material deposited successively on the walls of an open space. If the layers are symmetrically arranged on both sides of a medial plane, with crystals pointing inward, comb structure is produced. In the middle part of the vein there may be cavities or vugs lined with crystals.

(b) Banded structure by subsequent movement, or ribbon structure, produced by a simple sheeting of the vein material after original deposition. Such movement may result in a reopening along the new plane of movement and the deposition of new material in the opening.

(c) Banded structure by replacement, produced where the original fissure consisted of a number of parallel openings separated by thin bands of country rock and where, during or subsequent to the filling of these openings, the intervening bands of country rock have been more or less extensively replaced by vein material.

2. Breccia structure, in which the friable breccia or dragged-in fragments of country rock constitute a considerable part of the vein filling and the ore has been deposited in the spaces between the fragments, perhaps in more or less concentric shells or layers around them. Breccia structure may occur in any vein, hence it is not desirable to use 'brecciated vein' as a term of classification.

LINKED VEINS. Deposits that fill approximately parallel and over-lapping fissures, arranged in step-like form and connected or linked by small, irregular cross-stringers, are called linked veins. As the deposit pinches out on one fissure it is taken up on one of the over-lapping fissures.

STRINGER LOBE. A stringer lobe is made up of irregularly branching and anastomosing stringers or veinlets. In most stringer lobes the rock between the veinlets is so much metallized or is so inseparable from the stringers that the whole is worked as a single orebody.

CHIMNEY, STOCK. The term 'chimney' is applied to orebodies that have not the tabular form of a vein, but are rudely circular or elliptical in outline horizontally and have a very considerable vertical extent. A similar body of still greater irregularity of outline is called a stock.

STOCKWORK. A stockwork is an orebody of stocklike form made up of innumerable branching and anastomosing stringers.

ORE-SHOOT, PAY-SHOOT. An ore-shoot or pay-shoot is that part of a metalliferous deposit which is rich enough to exploit. Its outlines are not generally well defined. The ore-shoot may be considered as having three axes, at right angles to one another. The inclination of the longest axis to a horizontal plane is called the plunge and is measured in a vertical plane erected along the axis. The angle made by this axis with a horizontal line, measured in the plane of the vein, is called the pitch. In an ore-shoot that is part of a vein the dip of the vein and the plunge of the ore-shoot coincide when the pitch is 90°.

The true dimensions of an ore-shoot would be shown by giving the length of its longest axis and the area of one or more cross-sections normal to that axis. Inasmuch, however, as its true form can rarely be determined until all the ore has been mined, it is common practice to speak of its length and width or thickness as those of a horizontal section of the body on a given level of the mine. These are evidently not true dimensions unless the longest axis of the body is vertical. It is advisable to follow the usage adopted by Lindgren and Ransome in their Cripple Creek report and call the longest axis 'pitch length' and the horizontal dimension along the level 'stope length.'

CONTACT DEPOSITS. The term 'contact deposits' should be restricted to deposits which have been formed by igneous metamorphism and which carry the mineral characteristic of such action. Such use eliminates from this category many forms of deposit that have been so termed simply because they happen to occur between rocks of two different kinds. Contact deposits, as thus defined, occur mostly in limestone at or near its contact with an intrusive igneous rock. They are very irregular in form. Mineralogically they differ from other deposits by the contemporaneous formation of oxides and sulphides, principally of iron, and by the association of these oxides and sulphides with silicate minerals.

²Whitney, J. D. 'The Metallic Wealth of the United States Described and Compared with that of other Countries,' pp. 34, 49, 1854.

SEGREGATED VEIN. The term 'segregated vein' has sometimes been used to define materials that have been concentrated in a sedimentary bed. As a general rule, however, the name of a process should not be used as the definition of a type of deposit, and 'segregation' is more appropriately applied to the gathering together of material in a molten magma. In either sense reference to a deposit as 'segregated' does not sufficiently characterize it as a type.

IMPREGNATION. The term 'impregnation' has been used by different writers in many and conflicting senses. It properly signifies the introduction of mineral substances in a finely disseminated condition into rocks, either as a filling of open spaces or as a replacement of certain minerals. To describe ore occurring in small, irregular, disconnected particles throughout the mass of rock, 'disseminated deposits' is a preferable term, for it has no genetic signification.

PROCESSES

METASOMATISM. Metasomatism may be defined as the process by which, through chemical interchange, a mineral or an aggregate of minerals undergoes partial or complete change in chemical constitution. The term 'metasomatism' is of wider application than 'pseudomorphism,' for the process it designates does not necessarily involve the preservation of the crystalline form of the original mineral. It may or may not be accompanied by a change in volume.

REPLACEMENT. As a general term synonymous with 'metasomatism,' 'replacement' is preferable to 'substitution,' which is a chemical term strictly defined as "the replacing of one or more elements or radicals in a compound by other elements or compounds," a restricted usage to which 'replacement' is not confined. Replacement may be either partial or complete, according as only a part or the whole of one rock or mineral has been replaced by another.

ALTERATION. The term 'alteration' applies to the partial change of substance in a rock or mineral which does not necessarily involve its replacement by another. The process is purely chemical.

DECOMPOSITION. The term 'decomposition' signifies the decay of a rock or mineral into secondary products, usually accompanied by disintegration, so that it involves a physical as well as a chemical change and is most commonly effected by weathering.

WEATHERING. The term 'weathering' should be confined to changes in cohesion and composition of rocks near the surface by the decomposing and oxidizing action of surface waters, by variations in temperature, and by other atmospheric and surface agencies. The tendency of such changes is to destroy the rock as a geologic unit.

ENRICHMENT. In many sulphide deposits the valuable metals have been concentrated by solutions that have descended from the zone of oxidation. As commonly used the expression 'secondary enrichment,' although having some justification as an elliptic phrase, is

tautologic in form and should be avoided. The idea which this term is intended to convey may be expressed by 'enrichment,' 'secondary segregation,' 'downward enrichment,' or 'supergene enrichment,' according to choice or circumstances.

MIXING TERMS

In describing a mine it is well to state concisely the extent and character of the mine openings, for which the terms in general use, given in the following paragraphs, should be employed. If a local term, not in general use, is employed its meaning should be stated.

SHAFT, INCLINE, SLOPE, WINZE, RAISE, CHUTE, STOPE. The term 'shaft,' if not qualified, means a vertical opening starting at the surface. A shaft that follows the inclination of a vein or bed that is not vertical is called an inclined shaft, or simply an incline. In coal mines such an incline is commonly termed a slope. Passages within a mine driven upward from a horizontal gallery are called raises or upraises; those driven downward are called winzes. Inclined raises or winzes are often termed inclines. If used for sending ore down from a higher to a lower part of the mine such passages are termed chutes, ore chutes, or mill holes. A stope is an opening made in extracting ore.

TUNNEL, ADIT, DRIFT, CROSS-CUT, LEVEL. Properly defined, a tunnel is an underground gallery open to the air at both ends, an adit is open at only one end, and drifts and cross-cuts are horizontal galleries that do not reach the surface. In the United States, however, the term 'tunnel' has come into use among miners in a sense more or less synonymous with 'adit' and in this sense it is recognized by the mining law; hence it cannot be confined to its original meaning.

The following distinctions are made by miners and may well be observed in writing: A drift follows the general strike of an orebody, vein, or rock structure. A crosscut, as its name implies, crosses the trend of the ore or rock structure. Stations are roomlike enlargements of drifts or cross-cuts where they connect with a shaft. All the drifts and cross-cuts that connect on approximately the same horizontal plane with a station or with an adit constitute a level. If the level opens to the surface through an adit it is termed an adit level.

DIP, PITCH. Dip is the angular divergence of a bed or of a tabular deposit, such as a vein, from a horizontal plane. The term 'pitch,' originally used to signify the inclination of the axis of a fold from a horizontal line, has come into use among miners to express the inclination of the longest axis of an orebody or pay shoot within the plane of the vein. It should not be confounded with dip.

MINE, PROSPECT. It may be difficult to decide whether a certain property shall be called a mine or a prospect, and no hard and fast rule can be laid down for universal application. In general, shafts that are less than 100 feet in depth, with less than 100 feet of drifting, and that have not produced ore in commercial quantity should be termed prospects.

Cobalt, Ontario

Products, Supplies, and Power

The Dominion Royal Commission recently investigated conditions at Cobalt, and according to *The Northern Miner* the following notes are part of a memorandum presented to the tribunal:

Silver was discovered at Cobalt in 1903, but it was not until the following year that shipments commenced. The valuable metals contained in the ores are silver, cobalt, nickel, and arsenic. In most cases only the silver is paid for by the smelters, the other metals being saved by them as by-products enabling them to give better rates on the silver. In the early years of Cobalt all ore shipments had to go out of the country for treatment, most of it to the United States. Canadian smelters were soon started to treat high-grade ore. The latest development has been the operation of the so-called high-grade mills at Cobalt, which produce silver bullion by a combination amalgamation-cyanide process. An examination of the figures for the calendar years 1914 and 1915 shows that the percentage of silver bullion produced from Cobalt ores was in round numbers:

	1914	1915
	%	%
Cobalt mills, amalgamation and cyanidation.....	44	39
Southern Ontario smelters	39	45
United States smelters	17	16
Total	100	100

The quantity still going to the United States consists of some high-grade ore along with all the low-grade material, both ore and concentrates shipped, as the Canadian smelters are not equipped to reduce this. In the high-grade mills at Cobalt the silver only is recovered, the cobalt, nickel and arsenic being left in the residue for future treatment or sold for the cobalt-content. The Deloro and Coniagas smelters are equipped with complete refineries so that besides producing silver bullion they also produce and market arsenic, cobalt, and nickel. The cobalt and nickel have been produced mostly as oxides, but as there has recently been a market for the metals they are now also produced in that form.

The gross value of the silver ore shipments for 1915 to the mining companies was \$11,703,966; deduct dividends paid in 1915 \$4,523,414, and the cost will be \$7,180,552.

On the assumption that cash surpluses remained the same at the end of the year as at the beginning, it thus costs \$7,000,000 to operate the mines of Cobalt for one year. Of this amount it may be assumed that 40% was paid for supplies, or \$2,800,000. Some of the supplies used are given herewith showing quantity, value, and origin:

Cobalt and Porcupine combined use \$574,000 of cyanide per annum. Of this \$400,000 comes from the Cassel Cyanide Co. of Glasgow, and the remainder has been supplied by a German firm in the United States. From now on it is probable that all will be supplied by the Cassel company.

Cobalt and Porcupine use \$40,000 of pebbles per annum; all imported from Europe, mostly from France. Newfoundland had part of this market but lost it through shipments of poor material.

Cobalt and Porcupine use 200 tons of zinc, valued at \$80,000. This mostly comes from Japan at present, but soon it will be supplied from the United States.

Cobalt uses 900 tons of powder per annum, valued at \$450,000, while Porcupine takes an additional 1650 tons, and other smaller centres 80 tons more. All this is manufactured in Canada.

Cobalt uses 3,700,000 ft. of fuse per annum, valued at

MAP SHOWING PRINCIPAL MINING DISTRICTS OF ONTARIO.

\$17,000. Porcupine takes 7,000,000 ft. Of this 56% is British and 44% of United States manufacture. No fuse is made in Canada.

Cobalt uses 740,000 detonators valued at \$22,200. They are now manufactured at Brownsburg, Canada.

Drill-steel for Cobalt and Porcupine costs \$80,000. Formerly this was supplied equally by England and United States, but now England cannot supply it.

Lubricating oils, etc., \$40,000 per annum for Cobalt and Porcupine. All are American oils, but 30% is refined in Canada.

Power developments in the vicinity of Cobalt are as follows:

Hydraulic air-compressor plant at Ragged Chutes on the Montreal river has a capacity of about 5000 hp. of compressed air. The air is transmitted in pipes approximately 9 miles to the mines in the district. The main distributing system consists of 20-in. steel pipes with secondary and service lines of from 12 in. to pipes of smaller diameter.

Hydro-electric plant No. 1 is at Hound Chutes on the Montreal river 6 miles south of Cobalt, with a capacity of 4500 hp. Equipment consists of four 750-kw. generators, operating under a nominal head of 33 ft. Power is generated at 11,000 volts, and transmitted over pole-lines to Cobalt and vicinity.

Hydro-electric plant No. 2 is at Fountain Falls 4 miles below Hound Chutes. Two 1500-hp. vertical I. P.

Morris turbines direct-connected to two 1250-kw., 11,000-volt generators, operating under a nominal head of 30 ft., running in parallel with Hound Chutes and Matabitchouan generating stations.

Hydro-electric plant No. 3 on the Matabitchouan river, is 25 miles south-east of Cobalt. Equipment consists of four 1875-kw. generating units, operating under a nominal head of 312 ft. with a total capacity of 10,000 hp., at 44,000 volts. The transmission-lines consist of two circuits on separate poles extending from the powerhouse to South Lorrain and Cobalt, also operating in parallel with Hound Chutes and Fountain Falls plants.

The capacity and average power demand of various plants are as follows:

Station	Capacity horse-power	Present demand horse-power
Matabitchouan	10,000	9,000
Hound Chutes	4,500	4,000
Fountain Falls	3,300	shut-down
Ragged Chutes (air)	5,500	full load

The territory served embraces the Cobalt mining district where the company sells the bulk of its power at \$50 per hp.-year. The present demand for power is increasing owing to the higher price of silver, which has resulted in the opening of smaller mines and a more vigorous development on the part of the older mines. Also as a result of the improved methods the mines are enabled to treat their dumps and lower-grade ores. In order to find a market for the surplus power which is anticipated in consequence of mine exhaustion, there is now being constructed a transmission-line 65 miles north to the Kirkland Lake gold-field. As soon as completed this may give an additional 2000 or 3000-hp. load. This line will be designed to ultimately transit 5000 hp. The principal undeveloped water power now available is near the head of Lake Timiskaming on the Des Quinze or Ottawa river, 25 miles north-east of Cobalt. There have been several estimates made of the power, nominally amounting to about 150,000 hp. At the present time there is no market for such a development, although it is understood that a large pulp company contemplates getting power from this source.

Gold Output of the Rand for Half-Year

The total output to June 30, 1916, was as follows:

Waste sorted out, per cent	9.17
One treated, tons	14,171,862
Yield per ton	\$6.48
Working cost per ton	1.38
Total profit (95771,850)	\$27,850,000

Compared with the whole of 1915 when 28,311,579 tons averaged \$6.30 per ton, costs \$118.70, total profit of \$57,600,000 the current year shows an increased yield on a trifle less tonnage, with 20% extra cost and nearly the same profit, 2% per ton more.

Ordered orders on the U. S. Steel Corporation's books total 9,660,457 tons.

Acetylene v. Candles

By Warren G. Lenhart

With the use of acetylene, which tends to make the working-man safer and more efficient, there comes much criticism against the new and untried article, without first weighing its merits. The acetylene, or carbide lamp, when it comes to efficiency, is undoubtedly far superior to the candle. It gives a light more like the sun than any other medium. It is safer, cheaper, and allows both hands to do the work where formerly one hand had to be employed holding the candle. It holds-up its light in a draft in raise or drift. Taking safety as a basis for estimating its merits, it equals, if not surpasses, the candle. The latter at its best is a feeble light, and vitiates the atmosphere by taking-up the contained oxygen. Air in mines does not contain enough oxygen as it is, and by using a light that takes less than before, the men breathing such an atmosphere are benefited. The gas evolved through leakage is nil, and it would take 20% by volume to make the air polluted to such an extent as to make a man unconscious. The residue left in the bottom of the lamp is a disinfectant, being calcium oxide or lime, and is a good purgative when properly used. As superintendents and shift-bosses have good lights with which to inspect the miners' work, why not give the latter the same light to do their work.

This was written by an employee of the Anaconda company's Belmont mine, and the editor of *The Anode* added the following: Several hundreds of carbide lamps have been purchased for use in the company's mines, and it is expected that eventually they will entirely replace the use of candles. We are glad to publish these comments on the respective merits of carbide lamps and candles, and hope that they will remove any prejudices that may exist. The Bureau of Safety does not, however, recommend the use of spent carbide as a purgative. —*The Anode*.

PERHAPS the most marked feature in the history of power production has been the replacing of reciprocating machinery by that of rotary type. The steam turbine has invaded and captured a considerable portion of the fields of usefulness of the reciprocating steam engine. The centrifugal water-pump has replaced the reciprocating pump; rotary condenser auxiliaries are rapidly superseding reciprocating plant, and rotary air blowers and compressors have entered into successful contest with reciprocating compressors. The principal factors which have decided the issue in favor of the rotary plant are: small space, excellent balance, and low first cost and maintenance. In the case of the steam turbine there is the important additional advantage of using steam which otherwise would be wasted.—*Compressed Air Magazine*.

Iron ore imported during June were 134,151 tons. Ore is imported from Canada, Cuba, Spain, and Sweden. Exports in June were 204,558 tons.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

POWER CONSUMED by the Conrey dredges in Montana varies from 1.36 to 1.89 kw.-hr. per cubic yard of ground dug.

DOUBLING the diameter of a pipe increases its capacity four times. Friction increases as the square of the velocity.

FLOTATION of Mount Morgan gold-copper ore costs 34c. per ton of ore treated. Ten cents of this is for eucalyptus oil and residuum.

THE HEAVIEST SUBSTANCE known is osmium, which has nearly twice the weight of lead. The specific gravity of gold is about $19\frac{1}{4}$, while that of osmium is nearly $22\frac{1}{2}$.

OXYGEN in the oxy-acetylene jet ceases to cut when 16% of nitrogen is present. The cutting efficiency is directly proportionate to the percentage of nitrogen under 16%.

THE 'STANDARD CANDLE' is made of spermaceti, and burns 120 grains of spermaceti per hour. It serves as a standard for calibrating the intensity of electric and other lights.

GASOLINE HOISTS are frequently used underground in confined spaces, and miners would be wise to be careful, as fatal explosions have occurred when a dangerous mixture of gas and air is formed in such places.

OF 17,500 TONS OF COPPER produced in the United States during 1874, the Calumet & Hecla produced 87%. This was before the producing days of the great copper mines of the West, which began about 1883.

DANGER in handling calcium carbide in a mine is remote if reasonable care is observed with its use. The smallest proportion of acetylene capable of propagating flame in a mixture of acetylene and air is 2.53%; the largest proportion, 73%.

BLACK POWDER is still extensively used for blasting and mining purposes, but has lost its importance as a propellant in modern firearms, although still retained for blasting and other special purposes supplemental to the more important smokeless powder.

ALL ROCKS contain some water; but some, such as the granites, contain only an inappreciable amount. Sandstone, on the other hand, has an absorptive capacity of a gallon or more of water per cubic foot of rock, and is the best water-bearer of the solid rocks.

AIR-DRILL hose is often affected unfavorably by miners

pouring oil in the hose itself before connecting to the drill-machines. This saves them the labor of unscrewing the oil-plugs of the drill and replacing them. The oil may be good for the drill but surely is bad for the hose.

DESERT counties of California furnish the larger variety of minerals due to the climatic conditions that have prevailed there. Not only are the minerals found typical of mountainous regions, but in addition, they are typical of the dry plains and former marshes and lakes, such as the borates, sulphates, carbonates, nitrates, and chlorides.

LAST YEAR the Argonaut mine, the chief producer on the Mother Lode, California, produced gold worth \$775,928, from which a profit of \$447,317 was earned. The ore yielded \$9,268 in bullion, \$1,671 in concentrate, and 13.9c. in slime, so that the total yield was \$11,078. Therefore the cost was \$4.538 per ton. Construction expense was 35.5c. per ton.

SELECTIVE FLOTATION at the lead section of the Broken Hill South slime plant is giving satisfactory results, one week's run at the end of July showing the following: The feed averaged 10.5% lead, 7.4 oz. silver, and 12.3% zinc. This yielded concentrate assaying 61.8% lead, 45.4 oz. silver, and 10.6% zinc. The recovery was 88% lead, 90.9% silver, and 12.9% zinc.

CAUSE of the collapse of the bridge over the St. Lawrence river in Quebec on September 11 is ascribed to the failure of a cast-steel shoe upon which rested the south up-stream corner of the span being lifted into place. This shoe carried 1300 tons, one-quarter of the total weight of the span, and was part of one of the four lifting girders, one being at each corner of the span, and hanging from the ends of the cantilever sections of the bridge from each shore. The shoe should have been a forging. The whole span was of nickel-steel.

WAGES AND HOURS at Broken Hill, Australia, were adjusted by the Federal Arbitration Court in June as follows: an increase of 42 cents per day as compared with the rates under the previous agreement between the mine-owners and employees; overtime was increased from time and a quarter to time and a half and to double time, for ordinary days and Sundays and holidays, respectively; Sundays and holidays where continuous process is worked get a raise from time and a quarter to time and a half; underground men were allotted a 44-hour week, to be paid the same as if the former 48 hours were worked. Surface employees get a 16.6% increase, underground men 24.3%, and all employees 21.9%. The Broken Hill South company, which employs 400 on the surface and 875 in the mine, will have its expenses increased by a total of \$221,000 per year. Nearly all work in this mine is done on contract. During the half-year ended June 30, 1916, miners averaged \$4.12, and trammers \$3.42 per 8-hour shift.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

COMPENSATION IN MONTANA.—NEW HOIST AT BUTTE & SUPERIOR.
—NORTH BUTTE'S NEW MINING AND TREATMENT TESTS.—
ELECTROLYTIC ZINC.

The report of the State Industrial Accident Board shows that during the year ended June 30, 1916, there were 136 fatalities, 3 permanent total, 89 permanent part, and 6576 temporary disabilities. Of the last mentioned 1131 received compensation and 5145 returned to work within two weeks, and were therefore only entitled to medical and hospital attendance. It has been said that

"It is safe to say that under the old liability system not over 10% of the victims of these accidents would have had any standing in court; and if that number were able to reach a hearing before a judicial tribunal not more than one-fourth would secure a verdict, which would reduce the number recovering anything to a possible 4%. Computed on the ratio of average verdicts that have been secured in the industrial field in Montana on account of personal injuries, this would indicate a recovery of less than \$60,000, against the \$288,506 that has been paid out under the compensation system. Yet it is doubtful if the cost to the employers in paying out this enormous sum for compensation has exceeded the cost that would have incurred under the old system, with its heavy court cost and expensive army of high-priced attorneys."

The figures show that the cost of liability is between \$1000 and \$1100 per day. This is regarded as exceedingly low, and is attributed to the fact that the employers and employees are engaged in active rivalry to surpass in the safety-first propaganda. Cash prizes are offered to foremen and superintendents at mines, mills, smelters, and industrial plants, for the best records covering accident prevention. Aside from the humanitarian features involved, accidents now cost a certain amount of money and represent a fixed factor of expense. The man in charge of operation, as well as the men under him, is now held to a strict accounting for results in that line, as was formerly the case covering the amount of ground broken or the number of tons of ore extracted. There are 1518 employers actively operating under the act, which is about 98% of the employers engaged in hazardous industries who employ five men or more. The report shows that there are about 60,000 workmen who come under the act, that 17% were injured sufficiently to draw compensation, and 1% of the men killed had no beneficiaries, consequently no claims for compensation were filed.

The Butte & Superior's new hoist is designed to haul ore from a depth of 3000 ft. The 1800-ft. level is the lowest now being worked, so the hoist will fulfill all requirements for some years to come. The drums will be 9 ft. in diam. by 12 ft. face, and will wind the rope in two layers. The rope speed will be 2250 ft. per minute, and the maximum rope pull 4,000 lb. The hoist will be driven with a 100-hp. direct-current motor, receiving its energy from a fly-wheel generator set. The drums are so constructed that after reaching the 3000-ft. point new drum shells can be fitted, converting the drum into 12 ft. diam. by 10 ft. face, after which the rope will wind 5000 ft. of rope in two layers with a maximum rope pull of 52,000 lb. and speed of 3000 ft. per minute. When the change is made, and the 12 ft. drums are in use, a second 150-hp. motor will be installed on the other end of the drum shaft, and the fly-wheel set will be doubled. Control of the

hoists will be the Westinghouse standard type for limiting the acceleration and retardation. It will be operated by cams directly driven through gearing from each drum. A Welch safety-stop will also be fitted on, and it will take control when the electrical equipment fails and when no power is in use.

North Butte will develop part of its holdings in the eastern part of the district by a 2000-ft. adit that will soon be started on the Northwestern claim in Park canyon. The company owns 700 acres in this section. Part of it adjoins the Butte-Duluth, now being operated by the Frank interests of Salt Lake City. A large quantity of copper-carbonate ore is exposed at the surface on this property, but there has been no extensive development at depth. The Bertha claim of the North Butte adjoins the Bullwhacker, where silicate and oxide ores are being mined from open-cuts and where a vein carrying sulphide ore was recently cut at a depth of 100 ft. At another place the company's holdings touch the boundary line of the Butte Main Range, which is mining a narrow vein of 9% copper ore on its 500-ft. level. A compressor is being installed at the mouth of the new adit, and plans are being made to insure an average advance of 400 ft. per month. The adit will penetrate the foot-hills of the continental divide, and will cut the veins at a depth of 500 ft. This work is of a preliminary nature, and the information disclosed as to the situation, dip, and strike of the veins will be useful in determining the site for a shaft through which the property will be explored at depth. Conditions are favorable for the development of a large tonnage of silicate and oxide ores near the surface. At the present price of copper these ores could be shipped direct to a smelter. It is also probable that a method of concentrating will be devised. At present experiments are being made in coating the copper minerals with a film of sulphide, and then treating them by flotation. It is claimed that the tests have given good results, and that the silicates are successfully floated in the laboratory. The new development is two miles east of the Speculator and Granite Mountain shafts through which the whole of the present production is being hoisted.

Anaconda's new zinc plant at Great Falls made its first electrolytic zinc on September 11. Some of the aluminum cathodes were raised and stripped of their thin coating of zinc a few hours after the solution had been turned into the electrolytic tanks. The thin zinc sheet was quickly cut up into souvenirs. The plant has a capacity of 5,000,000 lb. of refined zinc per month, and all the units are expected to be in operation by November 1. The ore is mined at Butte, concentrated at Anaconda, and leached at Great Falls. The concentrates are roasted to change the zinc sulphide to a sulphate. The calcines are treated with sulphuric acid in 20 tanks, each 10 ft. diam. and 20 ft. deep. Compressed air is used for agitating, and the pulp then flows to Dorr thickeners. There are six of these 50 ft. diam. and 15 ft. deep. The overflow, after being filtered, goes to the electrolytic tanks, while the solution is taken from the thickened pulp by 12 Oliver filters. There are 720 electrolytic tanks 11 ft. long, 3 ft. wide, and 5 ft. deep. Each tank contains 281 of anodes and 27 aluminum cathodes. After the zinc is re-deposited, the solution is pumped back to the leaching tank. The electric power comes from the Big Falls and Rainbow hydroelectric plants situated a short distance down the river from Great Falls. The current is changed from alternating to direct by five rotary converters. It is expected that some ore will be shipped from the Douglas property in the Comstock district of Idaho to this plant.

TORONTO, ONTARIO

COBALT LABOR INVESTIGATION.—FLOTATION.—NICKEL REFINERY.

The Royal Commission appointed to investigate the labor difficulties at Cobalt has been in session and will shortly report. It appears that the principal difference was concerning the bonus of 25c. per day, which the miners were to receive during months when the price of silver averaged over 70c. per oz. They received this for one month, but when the price dropped the bonus ceased. The men object to their pay being regulated by the price of the product. Owing to enlistments and the high wages offered to laborers in munition factories there is a marked shortage of labor in all the mining centres, which, while it has not so far seriously affected normal production, tends to prevent the expansion of the mining industry.

The large flotation annex at the Coniagas has been started. It has a capacity of 600 tons per day, and will treat 100 tons from the mine and 500 tons of tailing from the dump. It is estimated that the accumulations of tailings for the last seven years amount to 300,000 tons, containing 1,000,000 oz. of silver.

The shaft being put down jointly by the Ophir and Peoples companies has reached a depth of 415 ft., just below the contact, where a station will be cut and exploration commenced by cross-cutting.—The Calumet & Montana Consolidated has blocked out a large tonnage on two levels, a considerable proportion of which is high grade.

It is apparently finally settled that the nickel refineries to be established by the International Nickel Co. and the British Canadian Co. will be in southern Ontario, somewhere near Lake Erie or Lake Ontario. Representatives of both companies have examined a large number of proposed sites, but are understood to have decided against construction in the northern mining districts on account of the severity of the climate during the winter. Favorable terms were offered by the city of Ottawa, but this, although considerably south of the mining centres, was regarded as too far north.

The INTERNATIONAL NICKEL Co. of New York announces that arrangements have been made for the construction of its new refinery to be built at Port Colborne, Ontario. The work will be carried out by The Foundation Company, Limited, of Montreal and New York.

SUTTER CREEK, CALIFORNIA

NOTES ON THE STRIKE SITUATION.—CENTRAL EUREKA IN AUGUST.

—SHAFT WORK AT THE PLYMOUTH AND BUNKER HILL.—
HARDENBERG MINE.

The following was written on September 19:

Later developments in the strike situation are that the miners held a mass meeting on the 19th at Italian Society park, between Sutter Creek and Jackson, gathering from all parts of the mining region in Amador county. Afterwards several hundred men paraded the streets, first at Jackson and then here, carrying flags and chanting Italian and Slavonian songs. The Sheriff had appointed and had sworn in a number of deputies. The South Eureka company has had several of its trusted employees provided with badges, not that violence is threatened but to be on the safe side. Contrary to first report, the three mines that have been paying their men the \$3.50 and \$3 demanded, are still running, namely, the Old Eureka, Keystone, and Original Amador. The other mines have simply retained their engineers, pump-men, and shaft-men, but the mine-owners' threat is to shut-down everything if the men persist in their demands for a 25-cent increase, and to have their time begin and end at the collar of the shaft. As it is now, in the more thoroughly developed mines, men claim that they lose from 15 to 90 minutes per day in getting to and from the working faces to the shaft-collar, partly due to the dis-

tance to be traveled in reaching the shaft and partly in waiting their turn on the skip.

The Kennedy, Argonaut, Bunker Hill, and Plymouth mines are the only dividend-payers along the Lode in this county; others are said to be barely keeping even, such as the Keystone, South Eureka, and Fremont; while the Treasure and Central Eureka are working on assessments, so there may be some justice in the mine-owners' claim that they cannot meet the men's demands at the present time. Little work is being done at the Original Amador. At the Old Eureka work is confined to unwatering and re-timbering the shaft and making surface improvements, so there are probably not over 100 men now engaged in actual mining, and there are said to be 1200 men out on this strike.

The Central Eureka company, whose mine is at Sutter Creek, has just issued the following report covering operations during August. The 2646 tons of ore crushed yielded an average of \$3.38 per ton. Earnings included \$4889 from 289 oz. of bullion, \$4040 from 56 tons of concentrate, and \$134 from sundries, a total of \$9063. Expenses included mining, pumping, and shaft repairs, \$9178; milling, \$1063; tailing-dam, \$518; sundries, \$1943; and indemnity insurance, \$405, a total of \$13,367. During the month 223 ft. of driving and raising was done, and a good deal of work in the shaft preparatory to sinking. There remained in the treasury on September 1 \$8596 from the last assessment levied, and when the shaft is put down for one or two new levels below 3200 ft., there is reason to believe that the property can be profitably operated. Fred Jost is superintendent.

Shaft repairs are in progress at the Plymouth Consolidated, as well as installation of the new electric hoist, which will be ready for operation by October 1. While similar to the machinery at the South Eureka mine, this hoist is much larger and is equipped with the latest improvements. The drum is 9 ft. diam., and the plant has a hoisting capacity of 1000 ft. per minute. By means of coarse crushing and re-grinding in Hardinge mills the 30 stamps reduced over 340 tons per day during August.

Reinforced concrete has been used at the Bunker Hill mine near Amador City to wall the shaft to a point 225 ft. below the collar, a new departure in Mother Lode practice. Square timbers, 14 by 14 in., and larger, are commonly used, the initial expense of concrete work being in most instances prohibitive here. However, as the shaft-sets, especially those near the surface, have to be frequently renewed, this will prove a saving in the end, particularly where the ground is loose and inclined to collapse. Only a few years ago a cave-in closed the upper portion of the Bunker Hill shaft and the men escaped through an adit or drainage-tunnel. Concrete ore-bins are also being constructed at the collar of the shaft so as to do away with the frequent re-building of the wooden structures. Good progress is being made with the installation of concentrators and rolls at the mill. The Bunker Hill mine is listed among Amador County's dividend payers, not having missed a single monthly dividend of 2½c. or more for nearly nine years. E. Hampton is superintendent and R. Christiansen foreman. Nearly all the men were laid off at the Bunker Hill mine prior to the strike, so that the shaft and surface improvements could be made without interruption.

W. J. Loring, who secured money to finance the Plymouth Consolidated, and who is interested in other properties along the Lode, has recently secured a three-months' option on the Hardenberg mine on the Mokelumne river in this county, 3½ miles south of Jackson. The Hardenberg has a 20-stamp mill, a three-compartment shaft over 1000 ft. deep, and is considered a valuable property. It extends 2300 ft. on the Lode, and has yielded good ore from a 6-ft. vein. Mrs. Kate N. Wells of San Francisco is one of the principal owners.

Up to going to press on the 26th there were no new developments in the strike situation. As reported on another page, the Plymouth mine is again in operation. There has been a little gun-play at Sutter Creek, but nothing serious.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

JEROME. Extensive work is contemplated for the Green Monster property. Two shafts are to be sunk 150 ft. on promising outcrops. The old Gorge adit on the Cliff claim has been put in order for 800 ft., and is to be extended 150 ft. to the contact. The Revenue adit is also being driven, with two cross-cuts. Camp buildings are being erected. A 6000-ft. pipeline has been laid. Electric machinery is arriving. Over 30 men are employed.

In the September Bulletin of the A. I. M. E., mine-fire

OATMAN. The U. S. Geological Survey, in charge of L. F. Biggs, is doing preliminary work for examination of this district.

On the 400-ft. level of Aztec shaft, 600 ft. east of the Big Jim end-line, the Tom Reed company has cut 18 ft. of good ore. Shares rose from \$1.59 to \$2.10.

The Golconda has let a contract for sinking its shaft 425 ft. The formation in this mine is andesite.

TUCSON. The Arizona State Bureau of Mines has received many requests from the East from people desiring to purchase

or lease talc and soapstone properties within this State. Although there are undoubtedly deposits of this mineral in Arizona, there are no records of any. To be commercial, a deposit of talc must be close to a railroad, although talc in extra pure form, such as may be worked for crayons, pencils, etc., brings as high as \$100 per ton. Soapstone is usually quarried, and while it does not bring high prices, it is easily mined and handled. The Bureau would be pleased to learn of deposits of this character.

ARKANSAS

YELLYVILLE. The Batty zinc mine, 8 miles north, has been sold to Senator Killiam and others of Locust Grove, Oklahoma, for \$20,000. New Jersey people held the property for some years, but did little work on it.

CALIFORNIA

The sequence of events during the strike along the Mother Lode since Tuesday, the 19th, is as follows:

The Mine, Mill, and Smelter Workers' Union issued the following statement:

"To the Workingmen of Amador County: The 25-cent increase in the daily wages asked by the miners has been refused by the mine operators, and all workers are requested to stay at home until the increase asked is granted. This is signed by the strike committee. All members of the Miners' Union are requested to meet in front of the Moose hall in Jackson at 1 o'clock, Wednesday afternoon, for a discussion of matters pertaining to the situation."

This affected about 1500 men, 800 of whom are unionists. About 400 men employed at the Old Eureka, Keystone, and Original Amador are working, as these companies raised wages some time ago.

The strikers are quiet and orderly.

For the first time in 30 years the Kennedy mine whistle failed to blow on the 19th. James Gianbruni, secretary of the Union in Amador county, cautioned the men not to use violence, and that they were willing to arbitrate the wage question.

Pumping is being done where necessary.

A parade of strikers was held at Amador City on the 21st, starting at Jackson and passing through Sutter Creek. Many banners were carried. It was expected that Western Federal

VERTICAL SECTION OF UNITED VERDE MINE AT JEROME, SHOWING SYSTEM OF VENTILATION.

methods employed by the United Verde Copper Co. are described by Robert E. Tally. The Plenum system is used, in which air of greater pressure than the gas from fires is forced into the fire-area.

MIAMI. The Inspiration is treating between 16,000 and 17,000 tons of ore daily. On No. 6 level a loco repair shop is being constructed. The reinforced concrete construction at shaft-stations and skip-pockets is a decided success in this mine.

MORENO. During the half-year ended June 30, 1916, the Shannon Copper Co. made a profit of \$131,220. On account of labor troubles only five months were productive. The copper output was 4,268,000 lb., at a cost of 17.2c. per lb. The price received was 27.562c. Current assets over liabilities amount to \$991,106.

tion of Miners officials would arrive on the following day, and on Sunday a big meeting would be held.

At the Plymouth mine, where all men are non-unionists, work has been resumed at the request of a majority of the employees. The force includes 225 men.

GRASS VALLEY. Three feet of good ore has been opened at the bottom, 1000 ft., of the Golden Center shaft. At this company's Allison Ranch mine the ejector has lowered the water 70 feet.

KENNETT. Material is arriving for the Mammoth company's electrolytic zinc plant to be erected above the copper smelter. Excavating is also under way.

PLACERVILLE. The main shaft at the Pyramid mine has been re-tembered to a depth of 500 ft. It is being sunk another 200 ft. Fifteen men are working in charge of Charles Evans.

For the first time in 22 years the Badger Hill deep-gravel mine is being worked. An adit 650 ft. long will be driven.

SCALES. The concrete debris dam being constructed on Slate creek, Sierra county, is expected to be completed in about four weeks. The first 50 ft. of height will restrain 4,000,000 cu. ft. of gravel. Los Angeles people are supplying the money. Karl Brehme is in charge.

TAYLORSVILLE. During the half-year ended June 30, 1916, the Engels Copper Co.'s gross earnings were \$475,579, and profit \$226,225.

COLORADO

LEADVILLE. Adjoining the Harvard on north Fryer hill, the Progressive mine is being re-opened in charge of W. F. Page. Old workings at a depth of 280 ft. are being cleaned out. The shaft is 375 ft. deep. Water and litigation resulted in the mine being closed years ago. By the drainage operations of the U. S. S. R. & E. Co. the Progressive is now dry. Diamond-drilling is to be done.

At the Harvard shaft-bottom the U. S. S. R. & E. Co. is cutting out a large shaft-station. One Byron Jackson and two Krogh pumps are to be installed, each of 500-gal. capacity. Sinking will then proceed for 300 feet.

On October 1 the Empire Zinc Co. takes over the property purchased from the Small Hopes-Boreel company. Zinc-lead ore is soon to be regularly shipped over a new spur-line that the D. & R. G. will construct.

Hartman & Mock, who recently discovered rich gold ore on Red mountain, in the Twin Lake district, have brought in a ton that will average 150 oz. per ton. Since this strike many claims have been staked around the original one.

SILVERTON. On Bear creek, 5 miles west of this place, Bliss & Ahearn have obtained a lease on the Coughlin gold-silver mine. A tram is to be built to carry the ore to rail, thence to a mill at Silverton. A mill is needed in the Bear Creek district, where are said to be several good properties.

IDAHO

Dividends paid by companies in the Coeur d'Alene totaled \$1,409,125 in September, as follows: Bunker Hill & Sullivan, \$163,500; Caledonia, \$78,150; Federal M. & S., \$120,000; Hecla, \$150,000; Hercules, \$200,000; and Interstate-Callahan, \$697,485. This makes \$2,674,961 for the third quarter, and \$7,557,807 for 9 months.

BURKE. The Hecla company is employing 300 men, and is mining 750 tons daily. A mill is leased at Wallace, but this arrangement is inconvenient and uneconomical, although justified by present conditions. The company's mill at Gem may be enlarged from 450 to 650 tons, as recommended by the president, James F. McCarthy. The cash surplus is \$400,000.

ELK CITY. At the Comstock at Dixie a two-compartment shaft is to be sunk to a depth of 500 ft. A power-plant is to be erected later on. T. H. Minear and C. E. Shepperd are owners of the mine.—Work continues satisfactory at the Mineral Zone, Black Pine, Grangeville, Gold Drop, and Black

Diamond. The last named is sinking to 1000 ft., and employs 45 men.

KELLOGG. During the second quarter of 1916 the Caledonia company's profit was \$287,932. Dividends absorbed \$234,480. Shipments were 4079 tons of ore and concentrate having a gross value of \$435,346, made up as follows: lead, 2,574,680 lb., \$188,146; silver, 294,242 oz., \$200,578; and copper, 167,233 lb., \$46,622. Smelter deductions for freight and treatment totaled \$110,927, making the net smelter returns \$324,419. The operating cost was \$36,486, of which \$29,726 was for mining, \$5852 for milling, and \$907 for shipping. Development was continued on the Keating tunnel level. So far this has been unsuccessful, finding neither the ore nor the vein. It is proposed to continue the search so long as there is a possible chance of success. There are 2 years' reserves opened.

LOON CREEK. The new 50-ton mill of the Lost Packer copper mine is giving good results. The process is simple, including a jaw-crusher, ball-mill, thickeners, and flotation machines. S. M. Morris was in charge of construction. The ore averages 4% copper and \$8 to \$10 gold and silver per ton. The plant may be doubled. Concentrate is hauled by motor-trucks, formerly by hundreds of horses, to rail, thence to Utah smelters. The local smelter is not used now. Hydro-electric power is available.

MULLAN. In a raise above the lower adit, in a distance of 4000 ft., the Silverado mine reports the opening of 6 ft. of gray copper ore assaying 50 oz. silver per ton. This is at a vertical depth of 1400 ft. A 100-ton mill is expected to be complete in about two weeks.

PINE CREEK. The option on the Douglas zinc mine in the Pine Creek district, held by the Anaconda company, has been extended for six months, according to official announcement at Butte. Development of the property under the Anaconda company's management is proving satisfactory.

MICHIGAN

THE COPPER COUNTRY

HOUGHTON. It is expected that the Ahmeek, Allouez, Calumet & Hecla, Copper Range, Hancock, Isle Royale, Lake, Mass, Osceola, and South Lake mines will produce more ore and metal during September.

At the White Pine Extension the shaft is down 200 ft. To test the ore by flotation a small plant is being erected.

Calumet & Hecla reports as follows for August and for 8 months, in pounds:

Ahmeek	2,173,439	15,375,731
Allouez	870,758	6,753,289
Calumet & Hecla.....	6,603,418	50,933,908
Centennial	207,486	1,667,445
Isle Royale	1,199,162	8,215,502
La Salle	109,032	835,220
Osceola	1,625,498	13,235,178
Superior	192,463	2,133,948
Tamarack	513,441	4,436,518
White Pine	426,152	2,894,565

The district's September output will be a good increase.

MISSOURI

JOPLIN. The largest shaft in the district, that of the Empire Zinc Co. at Galena, is down 90 ft. The opening is 6 by 15 ft. in the clear, and is to be sunk to 280 ft. Two by four-inch cribbing was used in the upper part, but 8 by 8-in. timber is now used.

Owing to better prices for ore last week there were larger 'turn-ins' of zinc and lead concentrates. The Oronogo Mutual company made a record of 488 tons. The output of the region was 6554 tons of blende, 138 tons of calamine, and 1102 tons of lead, averaging \$59, \$39, and \$69 per ton, respectively. The total value was \$471,902.

MONTANA

ANACONDA. The second of two cars of zinc carbonate ore from the old Blue-Eyed Nellie mine, 6 miles west of this centre, returned 38.85% zinc at the Bartlesville Zinc Co., Oklahoma. This is probably the first ore of this character shipped from Montana. In the late 80's this mine yielded a good deal of lead-silver ore. The ore occurs in limestone.

BUTTE. The Butte & Great Falls company has purchased the Snowdrift and Rio Tinto claims. This makes a property of 186 acres. Diamond-drilling is under way on the 500-ft. level. The shaft is next to be sunk to 1000 ft. In a 700-ft. cross-cut at 500 ft. depth are several promising zinc-lead-gold-silver veins. R. M. Green is manager.

In the eastern part of the Butte district the North Butte company is to drive a 2000-ft. adit to cut a number of veins at a depth of 500 ft. The company owns 700 acres in this section.

On the 100-ft. level of the Bullwhacker a vein of sulphide ore assaying from 4.94 to 21.24% copper has been cut. Some of the drillings assayed 3.5 oz. silver, the first time that any ore in this mine contained the precious metal.

ELKHORN. "Mining in Jefferson County" is the title of a leaflet compiled by C. H. Vorek and published by the Jefferson County Mining Bureau. The centre of the area is about 25 miles south of Helena. The districts are Amazon, Boulder, Cataract, Colorado, Elkhorn, Lump Gulch, Mitchell, Montana City, and Jefferson City. Capital and development are necessary for these districts. Elkhorn is the centre of a promising group of claims. The formation in granite, and the ore deposits are found in this and at its contact with limestone, also in limestone and andesite. The old Elkhorn mine has been a large silver-gold producer. It has large tailing dumps requiring treatment. Other mines yield copper and lead ore with the precious metals. The Golden Curry, Moreau, Montana & Dolcoath, Elkhorn Bulwer, Elkhorn Queen, Tacoma, and others are being actively developed, some shipping ore.

HELENA. Fifty-one miles from this place and eight from Flesher the O. & M. Mines Co. is completing a 150-ton mill. Ore reserves are 15,000 tons, assaying 60c. gold, 12 oz. silver, 15% lead, 1% zinc, and 1.5% copper. Development has been under way for a year. Forty men are employed in charge of H. Johns.

From October 1915 to September 1916, inclusive, the Scratch Gravel company's smelter receipts totaled \$119,947 net from 2847 tons of ore. The main shaft was sunk to a depth of 500 ft. Drifts on this level have opened 7 ft. of lode-matter which contains 12 to 30 in. of good ore. On the 250-ft. level there is 16 in. of \$65 to \$161 ore, and a stope assays over \$65 per ton.

IRON MOUNTAIN. The Intermountain company, operating the old Amador mine, pays a half-cent per share, equal to \$8000, on October 20. This is an initial declaration.

NEVADA

(Special Correspondence.)—The Nevada Consolidated is working full time, extracting 12,000 tons of ore daily, of which from 1800 to 2000 tons is from the Ruth mine's underground operations. The system of glory-holing a level underground by itself, one block at a time, appears to be working satisfactorily. This saves a great deal of timbering. Owing to the ground being of a swelling nature many of the main haulage drifts had to be re-timbered as many as a half-dozen times. One drill is prospecting the ground near Keystone acquired some time ago for dumping purposes, to ascertain if whether there is any ore underground or not. Two drills are prospecting in the bottom of the pits; also more drilling is being done continuously around the Ruth mine. It is understood that these results are satisfactory in proving the existence of more ore. At the smelter the roasting capacity is being enlarged. Work is progressing on additions to the crushing plant.

There are 45 men employed at the old Giroux, cleaning-up the Morris underground, also on the Coppermines proper, near the Star Pointer shaft. It is announced by the local management that the Salt Lake Engineering Co. has closed a contract to overhaul the old Pilot Knob Hill mill of the Giroux, to treat 1000 tons per day. They expect to be able to start with the first 500-ton unit within three months. Several millmen and carpenters are at work. The Callow system of flotation will be used. The public has been misled so many times with the Giroux that it will have to be shown, and by a new management.

The old Ward mine, 18 miles south of Ely, which has a past production of about \$5,000,000, now supposed to have 500,000 tons of low-grade silver-lead ore blocked out, is being reopened by Denver people, in charge of Mr. Johns.

The U. S. Tungsten Co. has leased most of its ground in blocks on a sliding-scale for the ore. Most of the tungsten properties, except Shepherds at Tungstonia, are closed down owing to low prices of the mineral.

Ely, Nevada.

GOLDFIELD. During August the Junbo Extension shipped 2444 tons of ore, averaging \$29.46 per ton. The net profit was \$23,000. Daily production is 100 tons, 6 days per week.

GOODSPRINGS. August shipments totaled 107 cars, containing 4815 tons. Of this, 70 cars were from the Yellow Pine, 6 from the Anchor, 4 from the Boss, and the remainder in 1 and 2 carload lots. The Boss mine has opened high-grade copper carbonate ore in a lower adit.

In Devils canyon the Christmas company is to re-erect a mill purchased from the Addison mine. A road had to be constructed through difficult country.

HORN SILVER. It is likely that a 100-ton custom mill will be erected for this district. For this purpose the Orleans Mining & Milling Co. has been formed with J. W. Dunfee as president, and E. C. Edwards of Goldfield as secretary.

ROCHESTER. At the Nenzel Crown Point mine the cross-cut was driven 415 ft. in 30 days. It is in a total of 1100 ft. Five well-defined veins of good value were cut, one being 85 ft. wide. The cross-cut will be extended to open the zero vein, which will also improve ventilation.

UTAH

ALTA. No. 4 drill in the Old Emma has passed through 21½ ft. of ore assaying 116.7 oz. silver and 8.5% lead, at a depth of 210 ft. C. S. Herzog is directing exploration, with J. J. Beeson as geologist in charge, the latter having said that the ore shows galena and pyrite disseminated through a compact mass of quartz, with here and there small cavities lined with well-formed crystals of quartz and galena. Argentite, the sulphide of silver, apparently is also present. This is further evidenced by the high silver-content in the first part of the core which was assayed. The unoxidized nature of the ore, the apparent absence of secondary minerals, and the large amount of quartz in the gangue, leads to the conclusion that the high-grade ore encountered will persist to depth. The character of the quartz as shown in the core indicates that the mineralization has been effected by deep-seated solutions coming up through fissures in the rocks and replacing the limestone. It could not possibly have come from waters infiltrating from the surface. In hole No. 2, 80 ft. away, the half-inch of galena is evidently connected with the body cut in hole No. 4, as was intimated at the time hole No. 2 was put down. The importance of this strike cannot be over-estimated. The actual visualizing of this ore is the only remaining proof that was needed in the chain of facts which have been gathered.

No. 6 drill hole has since cut 5 ft. of better ore than that passed through by No. 4. The ore contained more galena.

It is proposed to consolidate the Old Emma Mines Co. and the Emma Copper Mining Co.

PARK CITY. The Silver King Coalition Mines Co. distributed 15¢ per share on October 1, equal to \$187,500.

TINTIC. The Eagle & Blue Bell shaft is down 1876 ft. Production is restricted by the smelters to 50 tons of ore daily.

WASHINGTON

NORTHPORT. Two more furnaces have been blown-in at the smelter. Treatment problems are no longer a trouble, and the coke supply from British Columbia is more regular.

REPUBLIC. According to S. H. Richardson of the Knob Hill mine the silicious ore of this district is in great demand at the Trail and Grand Forks smelters, British Columbia. Greenwood and Northport also require some of the ore.

CANADA

BRITISH COLUMBIA

Dividends paid in September totaled \$413,877, as follows: Consolidated Mining & Smelting, \$210,688; Hedley Gold, \$60,000; Standard, \$50,000; and Crow's Nest Coal, \$93,189. For

IN THE HEDLEY DISTRICT OF BRITISH COLUMBIA.

the third quarter the total is \$855,738, and for 9 months \$2,520,591.

HEDLEY. On September 2 the Hedley Gold Mining Co. will pay its quarterly dividend of 3%, also an extra of 2%.

ONTARIO

COBALT. During August the Kerr Lake company produced 244,020 oz. of silver, an increase of 33,020 oz. over that of July.

PORCUPINE. The Hollinger is employing 1200 men. Foundations for the new mill are nearly finished. This will consist of 100 stamps, 10 tube-mills, etc. The new central shaft plant will be ready next March. The consolidated properties are being connected at the 425-ft. level.

On the 400-ft. level of the McIntyre the Jupiter vein has been cut. The mill is treating 400 tons daily. An aerial tram is to be constructed across the lake to haul 75 tons of ore per hour.

MEXICO

In the president's half-yearly report of the American Smelting & Refining Co. he states that the company has again to record the entire lack of earnings from its very valuable properties in Mexico.

The AMERICAN MINING CONGRESS will hold its 19th annual meeting at the Hotel La Salle, Chicago, during the week of November 13. A large attendance is expected, and interesting exhibits are to be shown. Papers are to be read by well-known mining men. J. F. Callbreath is secretary.

The MICHIGAN COLLEGE OF MINES at Houghton has issued its year-book of 113 pages for 1915-16, with announcement of courses for 1916-17. The fall term begins on October 2. A good map of the copper country is included.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

R. A. KINZIE is on his way to Arizona.

EDWIN E. CHASE and son are in southern Nevada.

ROBERT THOMSON, JR., has returned from Siam to Scotland, to enlist.

W. W. MEIN has been visiting the Mother Lode district, California.

HOWARD D. SMITH has returned from a visit to New York and London.

EDWARD H. COOK is returning to the Topia district in Durango, Mexico.

VICTOR C. ALDERSON and JOHN M. BAKER called at this office during the week.

W. H. STAYER has been at Silver Plume, Colorado, but is now at Washington, D. C.

T. M. SKINNER is assistant manager for the Potash Products Co. at Alliance, Nebraska.

J. O. CLIFFORD was in San Francisco on his way from Salt Lake City to Miami, Arizona.

W. D. ABEL is superintendent for the Three R Mining & Milling company at Patagonia, Arizona.

W. D. MANCHESTER is superintendent of the crushing department of the Chile Copper Co., at Chuquicamata.

FREDERICK R. BURNHAM is at the Pasadena hospital, where he has undergone the operation for appendicitis.

H. C. HARRISON is now operating the Three R mine at Patagonia, Arizona, having left Mexico for the present.

FRED HELLMAN has been appointed consulting engineer to Guggenheim Brothers, successors to M. Guggenheim's Sons.

W. A. CLARK, JR., WILLIAM BURGESS, and H. V. WINCHELL are visiting the Denning mining district in Owyhee county, Idaho.

GUY C. WARFEL has been appointed Assistant Professor of Mining Engineering at the State College of Mines of Washington.

ARTHUR K. ADAMS has left for Chile, where he will act as geologist for the Andes Copper Co., a subsidiary of the Anaconda company.

EDWIN S. BERRY, who has joined POPE YEATMAN in consulting practice, sailed for Peru on September 16 to examine mines in that country.

GEORGE R. ALLEN, manager of the Chosen Minerals Co., Seoul, Korea, is returning at an early date. He was recently at Atolia, California.

ROBERT E. CRANSTON has been appointed consulting engineer to the Mining Associates, Ltd., operating the Rawley mine, near Salida, Colorado.

S. M. MORSE has been appointed general superintendent of the Superstition Consolidated Mining Co., eight miles north-east of Price, Arizona.

O. J. FISK and R. J. GOODWIN are engaged in a series of chloridizing roasting and leaching experiments on the copper-platinum ores of the Boss mine, at Goodsprings, Nevada.

JOHN V. BECKMAN, for many years connected with the Lidgerwood Manufacturing Co., died at Plainfield, N. J., on September 11 at the age of 74. About 1870 he engaged in the manufacture of rotary engines, pumps, etc. His company was absorbed by the Lidgerwood company in 1873, Mr. Beckman assuming charge of the works of that company, and was the inventor of many improvements in hoisting-engine design. For many years he had been a member of the American Society of Mechanical Engineers.

THE METAL MARKET

METAL PRICES

San Francisco, September 26.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	23
Pig lead, cents per pound.....	7.25-8.25
Platinum: soft and hard metal, per ounce.....	\$90-95
Quicksilver: per flask of 75 lb.....	\$73
Spelter, cents per pound.....	12
Tin, cents per pound.....	41
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, September 26.

Antimony: 50% product, per unit (1% or 20 lb.)....	\$1.00
Chromite: 40% and over, f.o.b. curs California, per ton.....	13.00-15.00
Manganese: 50% (less than 35% metal not bought).....	11.00
Magnetite: crude, per ton.....	8.00
Tungsten: 60% Wb, per unit.....	13.00

Mica bulletin of the U. S. Geological Survey for 1915 is issued. Sheet mica averaged 68c. per lb., against 59c. in 1914 and 21c. in 1913. Mica must be 3, 6, 9, 14, 24, and 36 in. square. Bismuth in New York is quoted at \$5.50 per pound.

New York, September 29.

Antimony: There is no change, with the market at \$1 to \$1.10 per unit for prompt delivery.

Tungsten: Foreign business has been quiet this month because of cable delays. Foreign inquiries are still under negotiation, but domestic consumers are out of the market. The present quotation is about \$17 per unit.

EASTERN METAL MARKET

(By wire from New York.)

September 26.—Copper is active, spot metal is not quoted, and first quarter is 27.50c.; lead is also active, with good export demand; spelter is dull under reaction.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending

The silver market is strong with steady advances. London reports that fresh supplies are by no means plentiful, and the stock is only 7,000,000 oz., 75% of a month ago. China has not ceased releasing portions of its largely depleted silver currency holding. One of the Indian native states purchased \$480,000 of silver for coinage. The holding of silver coin in the Indian treasuries continues to shrink.

Silver worth \$591,000 (1,300,000 oz.) was shipped from San Francisco to the Orient on September 23.

Last week the Calumet & Hecla shipped silver worth \$35,000 from its copper refinery at Hubbell, Michigan.

Zinc ore at Joplin is \$5 per ton higher, the range for 60% metal-content being from \$50 to \$65 per ton. Butte & Superior concentrate, 53%, was worth \$19.45 per ton in August.

New Jersey Zinc shares are now quoted at \$315, giving the company a valuation of \$110,250,000. Earnings are at the rate of \$96 per annum.

When the American Zinc, Lead & Smelting Co. and Granby Mining & Smelting Co. merger is complete, the former will have 22,404 re-torts, with an annual capacity of 78,414 tons of spelter, and will rank as the third largest individual factor in the industry in the United States.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

ANTIMONY

The market is full of a heavy with re-sellers offering Oriental grade, at 11 to 11.50c. duty paid.

ALUMINUM

In the past week quotations strengthened somewhat, and up to 64c. was asked for No. 1 virgin metal, 98 to 99% pure, but the price has since settled around 61 to 63 cents.

Eastern Metal Market

New York, September 20.

Great quantities of copper have been purchased in the past few days, and the market is stronger. Near-by metal is scarce so far as the producers are concerned, some having but little metal not under contract for the remainder of the year. Near-by is quoted at 28.50 to 29c., and December at 27.75 to 28c. The enormous order of the Allies for 1917 has not been placed, but brass rod and disc requirements amounting to 40,000 tons have been covered. The large sales are quietly negotiated, and the prices obtained undoubtedly below what even large domestic consumers would have to pay.

Zinc has continued active, and is a little higher.

The A. S. & R. Co. has twice advanced its quotations for lead, now asking 7c., New York. Independents quote 7c. or higher.

Tin has been quiet, but the market expects a buying movement to develop soon.

Antimony is dull and easy.

Aluminum shows greater strength.

A leading feature of the steel trade is the overwhelming demand for plates, for which 4 to 4.50c., Pittsburg is now obtained. Middle Western consumers are begging the Eastern Pennsylvania mills for material. The demand for structural steel is not so urgent as that for other products. Independent structural shops took orders in August equal to 64% of their capacity. Generally, the tendency is toward higher prices as deliveries become more difficult. It is seen that Europe will take all the material that America can supply. Thousands of freight-cars are needed by foreign and domestic railroads. The plate mills are confronted with inquiries for at least 300,000 tons, deliveries to run through 1917. Three ships to be completed in the first quarter of 1918—about 18 months away—have been placed with Pacific Coast yards.

COPPER

So far as can be learned the requirements of Great Britain and her Allies for their first half of 1917 requirements, reported to be 125,000 tons, have not been satisfied, although negotiations are actively under way. In the past week, however, orders for at least 40,000 tons of brass rods and discs have been placed with brass mills, and the latter have either bought or obtained options on the copper and spelter required to fill the orders. Last week's business in copper is estimated at close to 75,000,000 lb. Near-by metal is scarce, in fact, there is not much to be had for the remainder of the year. One producer of electrolytic stated that he has none to offer this year, and wants 27.50c. for the first half of 1917. The exact level of prices is difficult to gauge for the reason that the near-by market is largely in the hands of second-hands, and a wide range of quotations prevails. Sales, to a large extent, are a matter of quiet negotiation, and sometimes details do not leak out. December is quoted at 27.75 to 28c. and near-by at 28.50 to 29c. Producers of Lake are sold-up to the end of the year, and its market is purely nominal, at approximately the same levels as exist for electrolytic. The London electrolytic market yesterday was stronger at £135 10s. against £132 a week previous. Exports from September 1 to 20 totaled 16,310 tons. Stocks in France and Great Britain on the 15th totaled 7118 tons, against 7514 tons, a decrease of 396 tons.

The general situation in copper looks strong for months to come.

Exports in eight months totaled 215,199 tons, compared with 171,786 tons in the period of last year. France took almost half, and England a quarter of this quantity.

ZINC

The market has continued active, although business has

been lighter than it was last week. It cannot be expected that a heavy movement will last indefinitely. The brass mills, which have booked the large orders for rods and discs, were active in covering their needs for these products. There has been a good demand for extra choice zinc, and for prime Western. The quotation for prompt prime Western at New York yesterday was 9.75c., and at St. Louis 9.50c. Fourth quarter was held around 9.37½c., St. Louis, and first quarter at 9c. Not only did the galvanizers take considerable quantities of prime Western, but that grade was taken also by brass mills which have come to using ordinary spelter for purposes for which "special" was formerly considered essential. It is conceded that the finished product is not as good as where brass-mill special is used, but it passes muster for various purposes. The trade is surprised that the recent buying did not send zinc up more sharply, and to higher levels than have been reached, and in explanation it is said that the smaller producers checked the advance by passing out their metal for disposal by dealers and brokers. Such activity as prevailed in recent days would have sent prices soaring a few months ago. Another influence, tending to keep the market down, is the quiet manner in which much of the buying has been done, thereby eliminating unnecessary competition. Makers of the higher grades of metal are well sold-up for the balance of the year. Exports of the month have been heavy, up to the 20th, totaling 6723 tons. The spot quotation at London yesterday was £56, against \$52 a week previous. The quotation for sheet zinc is unchanged at 15c., f.o.b. mill, carload lots, 8% off for cash.

LEAD

Buying of prompt and near-by metal has been active, and the excellent volume of orders which independent producers have been booking, many of them at premium prices, is the evident cause of two advances, each of ½c. by the A. S. & R. Co. On September 14 the company advanced its New York quotation from 6.50 to 6.75c., and on the 19th it made a further advance to 7c. Until the latter price was announced, independents had been easily obtaining premiums of ½c. or more over the quotation of the leading interest. Some of them are today asking 7.10c., New York. The St. Louis quotation of the A. S. & R. Co. is now 6.92½c. The independents are asking 6.85c. Up to the time the leading interest advanced from 6.75c., a heavy and widely distributed business was done. The big producer at the time was selling only to regular customers, and for October delivery, but only at its average price for that month. Outsiders made sales for October at 6.70c., New York. No surprise was expressed at the action of the A. S. & R. Co., the only wonder being that the advances did not come sooner. Near-by metal is scarce. Exports of lead have continued light, amounting so far this month to only 771 tons. The London spot market was quoted yesterday at £30 15s., or 15s. higher than a week ago.

TIN

The main feature in tin, which has been quiet in the past week, is that events are apparently shaping themselves for a good movement. It is some time since consumers have been in the market to any considerable extent, their contracts are nearly liquidated and their supplies must be getting low. Therefore sellers are looking for a movement in the near future. On one or two days in the week moderate interest was shown, but at no time was buying noteworthy. The spot quotation for Straits yesterday was 38.50c. The supply of Banca has been pretty well cleaned-up. Arrivals of the month up to yesterday totaled 1590 tons, and there was afloat 3590 tons.

Metal-Price Fluctuations During the War

THIS CHART, ORIGINALLY PUBLISHED IN *The Daily Metal Reporter*, NEW YORK, SHOWS THE MOVEMENTS OF METAL QUOTATIONS FROM JULY 1914 TO SEPTEMBER 1916, INCLUSIVE.

Prices of Old Metals

Nominal quotations in New York are as follows, in cents per lb.:

Heavy and crucible copper	23.00
Copper turnings	18.00
Heavy brass	13.00

Heavy lead	5.75
Zinc	6.75
Cast aluminum	32.00
Tin pipe	34.50
No. 1 pewter	23.00
Electrolytic scrap	6.50
Solder joints	8.25

EDITORIAL

T. A. RICKARD, Editor

THE American Mining Congress will hold its 19th annual session at Chicago on November 13 and following days. An interesting convention is assured.

MONEY is being made on paper at a terrific rate just now on Wall Street, but some of it will be like Carranza currency when the day comes for cashing.

ON another page we publish an account of the Institute meeting in Arizona. It appears that the visiting members saw a great deal and heard a great deal that was deeply interesting.

INTERNATIONAL Paper shares continue to soar, reflecting thereby the artificial rise in the cost of a product used by all of us and squandered by most of us, particularly the daily newspapers. If the high cost should lead to a diminished production of piffle, especially for Sunday consumption, the public would be benefited.

STOCK SPECULATION on Wall Street is becoming reckless, suggesting a fever of gambling that can only do great harm to the public. The decrease in the grain harvests, the labor unrest, the Mexican position, and the possibilities of complications with belligerents should deter the continued expansion in quotations. We are not out of the woods yet.

COPPER and the big dealings in that metal are discussed by our New York correspondent in his review of the market. He suggests that this big purchase of copper will be followed shortly by proportional buying of zinc, to make brass. Our own further remarks on the subject of copper quotations are held over until next week, owing to the exigencies of space.

OFFICIALS of the American Smelting & Refining Company are informed that bandits have burned the buildings and store-house at the Sierra Mojada mines, in Chihuahua. The American staff of the Real del Monte mines, owned by the United States Mining, Smelting & Refining Company, is returning to Pachuca, in Hidalgo. The reader can take his choice as to which incident best reflects conditions in Mexico.

BY Carranza's decree of September 12 any mine in Mexico that shuts down for two months consecutively or for three months in the aggregate per annum is to be confiscated to the Government, which also decides how many men are to be employed in order to comply with this ruling. However, such a pin-prick will not

add greatly to the injuries being done to mine-owners in Mexico. They are counting on a change of policy at Washington in March next. In our news columns we give further particulars concerning this latest decree of the *de facto* government.

CLASSIFICATION does not affect the thing classified, but it does affect the mental attitude and understanding of the classifier. For the sake of clear thinking correct categories are important, as Aristotle demonstrated some milleniums ago. The mental attitude of the American people toward the Mexican muddle will also be materially improved, with a hopeful probability of assisting thereby to a solution of some part of the problem, by adopting true definitions. The other day when Villista forces attacked Chihuahua it was reported as a "bandit victory"; when a Villista general meets with an unwelcome reception at Cusihuiriachic the "bandits are routed." The word 'bandit' in the English language signifies a group of common highway-men, out for plunder, and possessed of no patriotic aims. We as a nation shall gain a better perspective, and shall the sooner apply sane policies to the end of pacifying unhappy Mexico and of letting unfortunate American investors return to their work in the battle-torn republic if we cease to apply approbrious epithets indiscriminately to men who are fighting with a purpose, and recognize the fact that Carranza is dealing with sporadic revolution, likely to crystallize at any moment under some leader into formidable organized rebellion.

ECONOMIES effected in the production of copper are due not only to the rapid advance in metallurgy during the last few years but also to the improved methods of mining. In this issue we publish an article by Mr. George R. Lehman describing the practice of the Inspiration Consolidated Copper Company. As applied in the Inspiration mine it is a modification of the system used by the Ohio Copper Company in Utah, described by Mr. F. Sommer Schmidt in our issue of March 6, 1915. This method of mining is highly efficient and economical when applied to a large orebody of uniform grade covered by a cap that when under-cut caves readily but does not break into small stuff. Among the advantages are the small amount of timber required, economy in the use of powder, less shoveling, less danger of falls, and greater productivity in development work, which is done in the ore. A great deal of preparatory work is necessary before caving can be started, but in the interval it is possible to draw some ore. A disadvantage is the unavoidable mixture of ore with waste from the cap, reducing

the grade. What dilution is economic and what ore is likely to be lost must be determined by experiment. Care is necessary to avoid an excessive amount of waste, especially when drawing the last of the ore from a caved level. While the method is essentially the same in Utah and Arizona, a few changes have been made at the Inspiration mine. Less cross-cutting and driving is done on the caving-level, as the blocks are 25 by 150 feet instead of 20 by 50 feet. The drilling and placing of the holes has not been changed but the rounds are blasted singly, retreating from the edges of the block. As practised in Utah, the whole block of the caving-level is shot down by simultaneously firing all the rounds. The distance between caving-levels has been reduced from 60 to 35 feet. The success of the method is indicated by the cost, which is now 60 cents per ton and will be less when working the next under-cut.

Concreting a Shaft

The main shaft is to the mine what the trunk line is to the railroad. Safety is the first consideration, uninterrupted traffic the second. As a means to these ends the Copper Queen Consolidated Mining Company decided to concrete its Sacramento shaft. To do this without interrupting traffic was no small problem. The shaft was in constant use; the space between guides was so small as to be impossible of utilization for working-platforms. The fifth compartment of the shaft therefore was utilized as a passage-way for the concrete pipe-line, the concrete mixture being spouted by gravity into the forms through a 4-inch pipe in 10-ft. lengths in order that replacements for wear might readily be made in short, rather than standard-length, sections. Compressed air as a carrier for the concrete was employed, the air under pressure performing the double function of carrying the concrete to the forms and depositing it therein under such pressure as to compact the mass even better than could be done by hand-tamping. This method was used in San Francisco for both the Stockton Street and the Mile Rock tunnels, the concrete being so dense as to show the grain of the wood used for forms. At Bisbee the self-supporting steel forms were designed so as to be collapsible. The guides were left in place, the jar and vibration of the skips in passing having the effect of helping to shake the concrete into place in the forms, compacting the mass. Even the beams to which the guides were finally attached were of reinforced concrete. The total cost of the work was \$80,623; this includes all preliminary work as well as the actual concreting. The result is a fire-proof, practically water-proof, permanent main artery of traffic from mine to surface, through which ore, waste and men may pass without interruption as long as the mine continues to be productive. To the owner of a prospect, a concreted shaft would be an expense wholly unjustifiable. To the owner of a real mine, anything else is extravagant. When the character and volume of the ore deposit are such that the mine manager can see his way clear toward production for a term of years sufficiently long

to take into consideration the last as well as the first cost, the expense per ton of output per year for concrete as compared with wood should show clearly in favor of the former, leaving out of consideration the security from fire-risk. The Copper Queen Company is a pioneer in this type of shaft construction, although concrete has been used in shafts elsewhere in Arizona. The Bunker Hill Mining Company, in California, is about to undertake a similar work. Indoubtedly the article on the Sacramento shaft will stimulate other companies to do the same. We join with our readers in thanking the distinguished engineer that veils his identity under the initials 'G. S.' for placing on record his experience and that of his staff in this important engineering work.

The Wilmington Decision

On Saturday last Judge Bradford, of the U. S. District Court, at Wilmington, Delaware, filed his opinion in the case of Minerals Separation against the Miami Copper Company. The decision sustains the plaintiff, declaring infringement of claims No. 1 and No. 12 of the first patent and all of the second patent, but it declares invalid claim No. 9 of the first patent and all of the third patent. This opinion is based on the patentability of a reduction in the quantity of oil to less than 1% of the weight of the ore treated. At an early date we shall publish the full text of the decision. Meanwhile it may be explained that the first patent in suit is No. 835,120 issued on November 6, 1906, to Sulman, Picard, and Ballot. The corresponding British application for patent was filed on April 12, 1905. Claims 1 and 12 are as follows:

"1. The herein-described process of concentrating ores which consists in mixing the powdered ore with water, adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of 1% on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth, and separating the froth from the remainder by flotation."

"12. The process of concentrating powdered ore which consists in separating the minerals from gangue by coating the minerals with oil in water containing a fraction of 1% of oil on the ore, agitating the mixture to cause the oil-coated mineral to form a froth, and separating the froth from the remainder of the mixture."

Claim 9 is the broadest in the patent, it reads:

"The process of concentrating powdered ores which consists in separating the mineral from the gangue by coating the mineral with oil in water containing a small quantity of oil, agitating the mixture to form a froth, and separating the froth."

In this claim the proportion of oil is not specified; it is mentioned as "a small quantity." The second patent is No. 962,678 issued on June 28, 1910, to Sulman, Greenway, and Higgins. This patent is the one for a process in which a soluble frothing agent is employed. The third patent is No. 1,009,699 issued on June 9, 1914, to Min-

erals Separation as assignee from H. H. Greenway. This patent refers to copper ores and claims the use of an aromatic hydroxy compound, such as phenol or cresol, in a neutral solution.

The main feature of Judge Bradford's opinion is the patentability of a reduction of oil to less than 1%. The pioneers of the flotation process used as much as 3 tons of oil to 1 ton of ore, their method being based on the relative specific gravity of oil and water, and the affinity of sulphide minerals for oil; the Minerals Separation people claim to have reduced the proportion of oil "close down in the neighborhood of 0.1%," as their brief states. This is equal to two pounds of oil per ton of ore. Others operating on their own initiative since then have conducted the process most successfully with two-fifths of a pound or one-fifth of 0.1% per ton of ore. But the reduction in the quantity of oil is not the main distinction between the oldest and the newest phases of flotation, the latter use the oil not to buoy the mineral directly but to modify the surface tension of the water in the presence of plenty of air so as to produce a froth that persists long enough to float the mineral through the pulp and away from the gangue. Judge Bradford, in effect, endorses the opinion given by Judge Bourquin in the Hyde case when it was tried before the District Court of Montana and he disagrees with the reversal pronounced in that case by the Circuit Court of Appeals at San Francisco on May 4, 1914. Undoubtedly the Wilmington decision will be referred to a court of greater dignity, as happened in the Hyde case, which is now before the court of last resort. The present decision is immensely interesting, but it is not decisive.

The Far East Rand

This is an economic, not a political, designation. It refers to the eastern end of the great goldfield of the Witwatersrand, to an area of 240 square miles, of which 200 is underlain at a depth not exceeding 5000 feet by those beds of gold-bearing conglomerate from which nearly \$190,000,000 per annum is being extracted. Of the 200 square miles, 150 remain open to exploration. This represents a great economic asset, which the South African government would like to see productive. Of the annual revenue of the Union, one-half comes from the mines of the Rand. These are becoming exhausted at a rate threatening to throw the burden of taxation upon the other industries of the country, notably the agricultural, in which the Boer population is chiefly engaged. It is estimated that by 1929 fully half of the mines now productive will have depleted their supplies of ore; in 30 years the output will have fallen from \$190,000,000 to \$40,000,000 per annum. Hence the desire to promote the development and exploitation of the best remaining portion of the gold-bearing area.

The prospects are attractive. Up to the end of last year 11 companies had set to work in this eastern area, with results that speak for themselves: \$215,000,000 worth of gold has been produced from 26,681,884 tons,

and \$55,700,000 has been paid in dividends. The yield has averaged \$8 per ton and the dividends slightly more than \$2 per ton. The dip of the 'banket' in these mines ranges from 70 to 12°; in the unexplored area it is estimated that it will average 7°. The maximum depth of the workings is 4000 feet.

In 1908 the Government adopted a plan for leasing blocks of ground and in 1909 it invited applications for the right to mine on two areas, covering 1912 and 2037 acres respectively. Each application had to be accompanied by a guarantee of £35,000. It was estimated that £350,000 would be required in each case for shaft-sinking and preliminary development and a further sum of £350,000 for bringing the enterprise to fruition. Within two months after acceptance of the application, a limited liability company had to be registered in the Transvaal with a cash capital of at least £350,000. No shares were allowed to vendors or promoters, nor any underwriting commissions. The Government was to receive a proportion of the net produce, that is, of the profit after deduction for amortization of capital, on a sliding scale. Only one company, Barnato Bros., made application for both blocks. Later the Government offered sundry other blocks on successive occasions, but without tenders from the capitalists, who had come to a tacit agreement that the terms were not sufficiently attractive. Thus no business has been done since 1910.

A report was issued by the Government Mining Engineer, Mr. R. N. Kotze, early this year, reviewing the facts and suggesting amendments in the method of procedure, the principal change being to leave the initiative to the capitalist. A modification of the scheme of payments to the Government is also suggested. In addition to the ordinary profits tax, which is 10%, and the minor fees required by the existing law, the lessee will pay a further share out of his profit on a sliding scale. It is aimed to not penalize efficiency by exacting an increased share of the profit when this increase is due mainly to improved management, while allowing the Government to participate in the benefit accruing from a betterment in the grade of the ore. Mr. Kotze has suggested a modified formula, but his constants only cover particular conditions and it remains for him to devise, or for others to suggest, a scheme that will prevent an embargo on efficiency. This will be done, without doubt, for the Government Engineer has shown himself not only thoroughly capable but also fair-minded. Naturally, the Government wishes to have nothing to do with tonnage or any other arbitrary unit, the intention being to determine the profit made by the mine without the need for supervision; therefore the only factors considered are the gold placed in the bank and the cost as determined by an auditor, both items appearing in the company's published accounts.

More room for disagreement arises in the scheme of finance. The Government allows the operator to credit himself with 6% interest during the non-productive period preceding the commencement of milling and then allows 15% on the total accrued capital, together with 3% at compound interest for amortization, before ex-

acting its own toll on the profit of the operations. We question the soundness of this reasoning. Surely the money that is risked is deserving of at least as high a return before production commences as afterward; nay, is not the ratio of risk reversed, and should not the return be 15% at least before the productive period and more like 6% subsequently? When a mine of this character has been proved, when the ore is blocked out, the cost ascertained, and the future assured, then a return of 6% plus 4% for amortization of the principal should suffice, but until the undertaking is on a firm basis, while it is still an essentially hazardous venture, it should return a high interest, from 20 to 25%, to the operators. Then it is a 'speculation'; later it becomes an 'investment.' To this Mr. Kotze and many of the Rand engineers may demur, for they like to regard a Rand mining venture as *hors concours*, as something far less risky than the ordinary gold mine, as an 'investment' from the start. The story of the Witwatersrand flouts such unreasonable optimism; many of the sure things have proved disappointing; the mines have not been uniformly profitable. We repeat, the low rate of interest allowed during the incubation of the undertaking and the high rate conceded when the mine is firmly established on a fruitful basis is illogical.

Another factor regarding which a difference of opinion is permissible is the proportion of productive ground in the unexplored area. Mr. Kotze takes 60% as an average, the ground so far having been 15 to 85% profitably productive. Having regard to the fact that the most likely portion has been selected already, as far as can be judged by the evidence available, it seems to the observer at a distance that 60% is optimistic, and the assumption of it may retard good business, namely, the kind of business that proves beneficial to both parties in a given transaction.

Searles Lake Potash

In the news columns of a recent issue mention was made of the decision in the first stage of the litigation over the saline deposits of Searles lake in southern California. The matter is one of importance because this deposit is likely to become an important source of potash and the effort to exploit it has been under way for several years by a corporation financed by the Consolidated Gold Fields of South Africa, a British company that has played a big part in the development of the Transvaal and Rhodesia. The story of Searles lake and its mineral encrustations is worth reviewing. In January 1908 this lake-bed in San Bernardino county was located as a soda deposit by C. E. Dolbear, acting for himself and seven others, most of whom were resident in New York and New Jersey. These locators sold out shortly afterward to the California Trona Company, which borrowed money from the Foreign Mines Development Company, a subsidiary of the Consolidated Gold Fields of South Africa, a London corporation. The loan was secured by a mortgage that was foreclosed in 1909, the

final decree being granted in 1913. Control of the shares of the California Trona Company was acquired in 1911 by Mr. Guy Wilkinson, managing director for the Foreign Mines Development Company, so that title was vested in an American. Attempts to jump the locations were made in the spring of 1910 by Henry E. Lee. He sent a young engineer named Davidson, who died on the ground; and the survivors of his party assigned the locations they had made to the Trona company. In the autumn of the same year Mr. Lee sent another party, this time armed, for the same purpose, of locating claims, on the assumption that the original Dolbear locations were invalidated by the so-called Yard decision, in which case the Government had disallowed the placer claims staked by locators that had not shown good faith by supplying funds or appearing in person on the ground. Within a week after Lee's locations were made, one of his associates attempted to sell the locations to the Foreign Mines company and suggested that if they bought them the company could freeze out the real owners of the property—the California Trona Company—and obtain possession of the property. At that time—1910—the Foreign Mines company held only 10% of the Trona company's stock; the control not being acquired until 1911, as already stated. But this indirect attempt to force the position failed; the manager of the Foreign Mines company rejected the proposal indignantly. For several years thereafter the Lee locators made a pretense of doing assessment work, coming in conflict with the representative of the U. S. Court, which then had possession of the property on the appointment of a receiver in December 1909. This episode was known at the time as the 'Trona war,' and enabled the daily press to publish a lot of piffle. Only one shot was fired, and that in error. The quarrel did not come to trial then, the contestants expecting to be bought out; in fact, it has been testified that \$180,000 was offered by the Foreign Mines people, but it was refused, fortunately for them. Suit was finally started when the Trona company applied for patent in 1912, but the attempt to adverse was dismissed. Then a suit to quiet title was brought in the Superior Court of San Bernardino county and it is this suit that was decided on September 11 in favor of the defendants, the California Trona Company and others. The decision is sweeping and amounts to an affirmation of title, subject to the decree of the Patent Office, which still has to pass on the validity of the locations.

Potash had been discovered originally by Mr. Whitman Symmes in 1898, but there being no market for that salt, the existence of it in the Searles Lake deposit was ignored until 1912, when the fact was established and given publicity by the U. S. Geological Survey. The War, of course, has enhanced the value of the potash by stopping importation of the products formerly exported from Germany by the Kali syndicate. A plant to extract potash from the Searles Lake salts has been built at San Pedro, near Los Angeles, and we are informed that potassium chloride is being produced in a small way, with expectations of increasing the output shortly.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Basic Lining

The Editor:

Sir—I am surprised that you would allow your paper to print such an incorrect statement as that on page 426 of your issue of September 16:

"Probably the first attempt to use a converter lined with basic material was that by the late Charles F. Shelly at Cananea in 1907. He gave up the trial as impracticable. Some months later, Messrs. Smith and Pierce proved the basic lining a success at Baltimore and Garfield."

If you will look at a copy of the *Mining Journal* for March 24, 1906, you will see a description and report of the operation of the basic-lined converter, lined with magnesite brick, from August 18, 1905, to February 21, 1906. Mr. Baggageley was the first man to successfully smelt ores direct in a bath of molten matte in a basic-lined converter. He had no water-concentrator. He convinced the Guggenheims of this only when he told them to go to the books of the Nichols Chemical Co. and look at their books showing the shipments for eight months from a plant that had no water-concentrator. Smith and Pierce tried out the process at the Baltimore converter and then sent a lawyer from Baltimore to offer \$5000 for two of Mr. Baggageley's patents, then owned by the East Butte. The ignorant officers of the old Pitts-mont company here telegraphed to Col. Paine for advice. He consulted by telephone with the Nicholas Chemical Co. and they told him to ask \$25,000. Col. Paine asked \$20,000 and the lawyer paid it. Smith and Pierce in that first year collected a quarter of a million dollars on the infringement of those two patents. Sixteen others were being infringed at that time, but were all being ignored and unprotected by the company to which Mr. Baggageley assigned them. He bought the Pittsburgh & Montana property in the flats of Butte, because he said there was pay-ore there if you went deep enough for it. The mining world and the Government geologists said he was wrong. Look at the reports of the East Butte today and see who was right. And they are only at the top of their rich ore now. Mr. Baggageley was not ignorant, like your writer, of all previous trials of smelting in this way, but wrote a complete history of it, and its failures, and why each man failed. Copper was being produced in Butte in 1906 at from 7.57 cents to 9.69 cents. Mr. Baggageley produced it from lean ores from 4.84 cents to 5.71 cents. This was in 1905 and 1906, and your paper dared to print that the first successful trial

was in 1907. You should be more familiar with the history of copper smelting.

EFFIE I. BAGGAGELEY.

Pittsburg, September 22.

[Mrs. Baggageley will find, by reference to the offending article, that the statement to which she objects was contained in an article published by the American Institute of Mining Engineers and abstracted by one of our staff for publication in our paper. The blunder, however inexcusable in the first instance, should never have been made in our pages, for Ralph Baggageley was well known to the present writer and so was his work in connection with the introduction of the basic lining. In regard to the Pittsburgh & Montana property, the last report made by the present writer, in 1902, before he ceased to practice as a mining engineer, on becoming editor of the paper at New York, was a report on the ground to which Mrs. Baggageley refers. He advised Mr. Baggageley against the venture, telling him that "the ante was too big for the game," that is, the preliminary expenditure, in exploration, development, and equipment was not justified by the evidence of richness. It would be a pleasure to the present writer to learn, now or at any future time, that this part of the Butte district had proved the scene of profitable mining.—EDITOR.]

A Patent-Office Joke

The Editor:

Sir—My susceptibilities were greatly agitated by a recent patent (No. 1,185,902) that filtered into a (Royal S.) Handy beaker on June 6, 1916, and to which my attention was recently directed in your columns. Evidently an Idaho school-boy lost his elementary chemistry, for the chemical tutor in Washington passed, with a mark 100, the following chemical equation:

I object. It is I. Oxygen (O_2), and not my *alter ego*, Ozone (O_3) that attaches itself to PbS. I do not love galena, but when driven to the attack by heat of chemical emotion, I cling to her with a powerful embrace, and when I do my dusky bride turns pale. My *alter ego* is never known above 300 C. as his soul then becomes mine.

What a shock! SO_2 is an old affinity of mine, but she is coy and insists on proper nuptials. Oft I ask her, but

never may I wed her except in the presence of a duly ordained clergyman. My relative, Nitric Oxide, and old father Platinum Black are our favorites. There are others. Silica is also a relative of mine, but alas! he is an insoluble enigma.

Hurrah for my children! Right you are!

Once more unto the breach, dear *alter ego*. Show yourself brave and stick to your trenches in spite of the heat of the attack. Glory be to you for your discovery of native FeS in quantity. My find is usually FeS₂.

Shades of Dalton and Lavoisier! What have we here? The sign of inequality?

When two makes three

And three makes four,

Take some of me

And faint no more.

OXYGEN.

Tax on Mine Products in British Columbia

[The following exchange of letters is self-explanatory.—EDITOR.]

Mr. Wm. Fleet Robertson,
Provincial Mineralogist,
Victoria, B. C.

Dear Sir:

We have heard that your Government is levying taxes upon net proceeds of mines as a War measure. Can you give me any information regarding this matter? I know that the fact that such taxes have been levied, or are in prospect, is causing American mining men to hesitate in making any investments in British Columbia.

Yours very truly,

G. W. SMITH.

Butte, August 26.

G. W. Smith, Esq.,
Butte, Montana.
Dear Sir:

Replying to yours of the 26th inst., there has been a lot of talk on your side of the line regarding the so-called War tax, and I have had to answer innumerable inquiries.

The Act assented to May 18, 1916—is known as "The Business Profits War Tax Act, 1916," and is being administered in the Western Provinces by Mr. A. G. McCandless, 241 Winch Bldg., Vancouver, from whom you can obtain copies of the Act and any official information desired. Briefly, the following is the substance of the Act: A company is allowed to make 7% profit and an individual 10% clear of taxation. From the gross profit deductions are allowed for working expenses, deprecia-

tion, exhaustion of ore reserves in a mine, etc., etc. In other words, profits are absolute dividends. For profits over amounts stated the tax is 25% of such excess. For example, a company making a clear profit of 11% (7% plus 4%) pays a tax of 1%. The Act is a War measure, and is for the duration of the War and a short time afterward.

I think you will agree with me that there is nothing so very dreadful in all this, and if any company is not prepared to pay this amount out of profits made from Canadian mines or business—to assist in this War—then most heartily we do not want them or their money in this country.

I am, yours very truly,

W. F. ROBERTSON,
Provincial Mineralogist.

Victoria, B. C., August 29.

Field-Signaling

The Editor:

Sir—I have noticed with interest the article in your issue of September 16, with reference to field-signals, and believe your correspondent would be interested in the more complete and well established system of semaphore signals used regularly in the United States Navy for communicating from ship to ship.

The system that your correspondent proposes has the disadvantage, in signaling letters after J in the alphabet, that two symbols must be used instead of one. In the semaphore alphabet, which is formed by different positions of the hands and arms, this is not necessary. The semaphore system is completely worked out with a series of secondary meanings for the different letters. For example, K equals 'No' or negative; P equals affirmative or 'Yes'; L equals preparatory; O is a question or interrogatory, and so forth.

No doubt, many engineers and miners are acquainted with this code, which has been in general use for a long time. Many of the Navy signals are given in the form of a three-letter code and something of this sort could be worked up for field use by surveyors and engineers. The hand-signals can be seen at a considerable distance, and if long signals are to be given at great distances, a pair of flags about 15 inches square on 18-in. sticks will be found a great assistance. Those used in the Navy are half red and half yellow, divided diagonally across the field. This system is much more rapid than the ordinary Morse wig wag, as but one position of the hands is required to form a complete letter.

A CIVILIAN NAVAL VOLUNTEER.

Chicago, September 20.

DREDGING at Pato, Colombia, the Oroville company saved gold worth \$21,372 from 85,942 cu. yd. of gravel in 18 days during August.

GOLD OUTPUT of the Mysore mine, the largest in India, amounted to \$343,000 from 26,642 tons of ore in August.

Concreting the Sacramento Shaft at Bisbee

By G. S.

INTRODUCTION. It became necessary in 1915 to re-timber, or otherwise secure, a part of the Sacramento shaft, the main hoisting-shaft of the Copper Queen Consolidated Mining Co. Re-timbering would cost less, but a concrete lining would eliminate fire-risk and cut repairs to a minimum.

Either operation, re-timbering or lining with concrete, was complicated by the necessity of hoisting nearly all the ore mined in the Copper Queen mine through this shaft. It was estimated that the required production could be made by hoisting 14 hours per day, leaving 10 hours for work in the shaft.

A general plan and comparative estimates of cost were prepared, and in March 1915, twenty-five feet of shaft was concreted to test the method and estimate of cost. Certain experiments were made at the time to secure information on a few details of operation.

After it was decided to concrete the shaft, a quarry for crushed rock and sand was opened, storage-bins at the shaft were built and forms were constructed. The first 5-ft. section of concrete was poured on October 17, 1915, and the collar set on July 30, 1916. Since then, a ladder-way and a new set of guides for the skip-compartments have been put in, with regard to convenience rather than speed, and the work was finally completed on September 3, 1916.

GENERAL PLAN. A crushing-plant at the quarry produced both coarse rock and the fine material used as sand.

There is no railroad-track above the Sacramento shaft. The sand and rock were brought to the shaft by railroad, and there elevated to storage-bins. It was trammed to the concrete-mixer through an adit-level 71 ft. below the shaft-collar. The mixer was placed below the adit-level, in a set adjoining the fifth or pipe-compartment of the shaft. After mixing, the concrete was dropped into a hopper and through a 4-in. pipe in the fifth compartment to the forms below.

The lining was made at three different points alternately to give time for the concrete to set properly before the forms were stripped. This was to permit single sets of forms to be used, as was found most convenient.

The skips and cages were fitted with top decks to work from, and additional temporary bonnets were clamped to the ropes above for safety. When the timbers were removed, they were dropped into the skips or lashed on the cages, and taken to the surface when convenient. This was believed to be safe with the powerful hoisting-engines operating them, and avoided the use of working-stages, which would have taken too much time to put in and remove.

QUARRY AND CRUSHING PLANT. In crushing, a con-

siderable quantity of sandy material is produced, which is customarily used to replace a part of the necessary sand. It was believed that by separating with a coarser screen and installing a set of rolls, sufficient sand could be crushed more cheaply than it could be obtained otherwise. Samples of rock crushed through $\frac{1}{2}$ -inch screen gave satisfactory results under test. Since it was necessary to open a quarry and provide a crusher, screen, and bins, only the addition of an elevator and rolls were needed to produce sand as well. A 10 by 20-in. jaw-crusher and a set of 15 by 26-in. rolls were obtained from the smelter, and a small plant with elevator and trommel erected.

Power was furnished by a 50-hp. induction motor.

The coarse material having to pass the 4-in. pipe, was reduced to a $1\frac{1}{2}$ -in. ring. Material passing a $1\frac{1}{2}$ -in. ring was sent to the rolls. This did not provide sufficient fine, so holes were increased in number and reamed out to 1 inch. A third product was made passing a $1\frac{1}{4}$ -in. ring. Since another elevator would have been required to return the oversize to the rolls, the fine was used as it came. This product contained a good many coarse pieces. It was not convenient to re-screen and send the oversize to the middling-bin, so a greater quantity of fine was used to give sufficient sand. The only difficulty was when mixing small batches, as, for instance, for the concrete beams. Then there was apt to be segregation, and the mixture was uneven. For this purpose, it was screened and the oversize thrown into the middling. In batches of ordinary size for the shaft, no difficulty was encountered.

The quarry was started where rock comes to the surface, and a good working-face was soon obtained. Drilling was done by jack-hammer, one machine breaking all the rock required. Only clean rock was sent to the crusher, earthy material being left on the floor of the quarry. A track, 41-in. gauge, of 16-lb. rails was laid from the crushing-plant to the quarry, and branched to control the whole face. The rock-cars were built broad and low, for convenience in loading. They were dumped by raising the tail end by a compressed-air cylinder.

The rock from the car dropped five feet to the crusher, where there was only storage for a carload or so. The crushed rock dropped into the boot of a bucket-elevator, which raised it and dumped it into a revolving trommel. The fine material from the first section dropped directly to the rolls below, and from them into the fine-bin. The second section delivered the middling product into the second bin, and the third section the coarse aggregate into the third bin. The oversize was returned by a chute to the crusher and continued the circuit.

TRANSPORTATION. The concrete material was loaded

from the bins into Rodgers ballast cars and switched to the Sacramento shaft.

STORAGE BINS. The railroad track at the Sacramento shaft is too low to dump the cars into storage-bins from which it could be delivered by gravity to the mixer. A spur was therefore laid over a shallow hopper-bottom bin, holding a carload of rock or sand. A belt-conveyor under the receiving-bin carried it to the foot of an elevator, which lifted it to the top of the storage-bins and delivered it into one of the three compartments. The bins were constructed almost entirely of nine-timbers, framed for ordinary purposes and bolted together. When it is taken down, the timber will have its original value for use in the mine.

The chutes from the storage-bins form measuring-pockets for a batch of concrete. The proportions were determined by customary methods of experiment.

Opposite the bins, a small house was built beside the railroad track for cement storage, and sufficient cement for a section was taken on trucks to the mixer-station immediately before use.

THE MIXER was a half-yard Ransome machine, and was set just below the adit-level, in an excavation made for the purpose facing the fifth compartment of the shaft, with the loading-hopper flush with the floor. After mixing, the concrete was discharged into a hopper that formed the whole bottom of the fifth compartment, and connected with the 4-in. pipe. The sides of the hopper were built at 40° from the horizontal, which facilitated feeding better than a steeper angle.

The water was measured in a tub with a quick-discharge valve.

CONCRETE PIPE-LINE. It was impossible to put the concrete line in any one of the central compartments, since they were in constant use; therefore it was placed in the fifth compartment of the shaft. It was inserted at once to the bottom of the shaft, and shortened as the shaft was finished, from the bottom upward. The line was made of 4-in. standard pipe, threaded deep enough to let the end come clear through the flange, and all lengths were faced in a lathe after flanging, to an exact length of 10 ft. The flush joints left no irregularities on the inside surface to start erosion, and by making all pipe lengths 10 ft., any piece could be replaced without trouble. At the upper points of work, a length of pipe was taken out to attach the elbow, and if necessary, a 5-ft. length was slipped in, to deliver the concrete at the proper point above the form.

The shaft was so long that concrete could not be spouted to the forms at the opposite end without great difficulty in handling the spouts. An elbow was therefore attached to the lower end of the column, and the concrete shot to the form by compressed air delivered at the back of the elbow. In turning 90°, the elbow expanded from four to six inches in diameter, so that there would be little chance of clogging. Short pieces of 6-in. pipe of proper length were attached to the elbow to carry the concrete to the other end of the shaft. At the end of the short pipes, a 45° malleable elbow was attached,

loose on its threads, and a short piece of 8-in. galvanized iron pipe was slipped loosely over it and the short nipple in the elbow. By turning the elbow on its threads, and using the loose fit between the 6 and 8-in. pipe for further change in angle, it was possible to deliver the concrete wherever desired.

It was planned to begin concreting in the fifth compartment, which contains the concrete column, and build out to the far end, but this was changed afterward, and work begun in the skip-compartments, in order that they might be freed more quickly for hoisting ore, which often began before the other part of the shaft was finished.

It was at first thought necessary to discharge the concrete in an open bucket below the straight pipe, as at the Old Dominion and Junction shafts, and let it overflow into a short length of pipe down to the compressed-air elbow close above the forms, for fear of clogging at the elbow and building up in the vertical pipe, but it was not needed, and eliminated a great obstacle to rapid work. The first few rounds of the trial section were poured with the bucket, but in the last, the elbow was attached to the column direct. The first elbows were cast of manganese-steel, but wore rapidly. Later, when others of plain cast-iron were used, forged patches, which lasted a long time, were bolted over the hole when formed, which was always straight under the vertical pipe. In all, six elbows were used. The column lasted well. The sections removed at the lower end were used to replace others above, that were worn out. Sixty-seven 10-ft. lengths of new pipe were required in addition to the original equipment. Much of the column is in fair condition still.

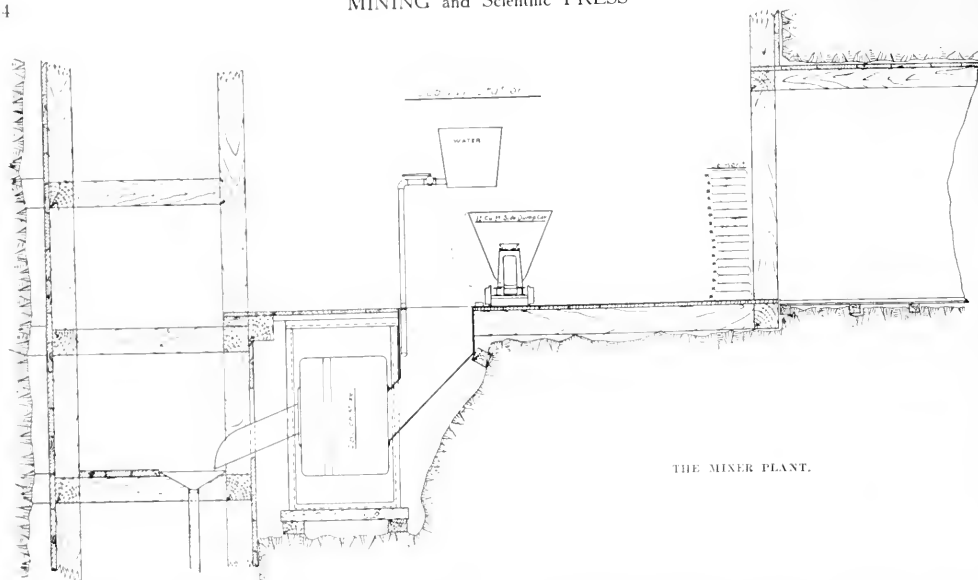

FORMS. The shaft has five compartments; two for skips, two for cages, and one for air-columns, power-cables, and ladders. The skip-compartments are separated from each other and from the cage-compartments by solid walls of concrete 10-in. thick, pierced by windows for access to them and for ventilation. These are placed in every alternate 5-ft. section, and are closely planked between the adjoining cage and skip compartments, but are left open between the skip-compartments, to permit air to pass the skips on its way to the ventilating fan on the 1600-ft. level.

The forms were the most original and important factor of the operation.

It was essential that they should be self-supporting, outside of the space required for cage or skip, and it must be possible to take them down and re-set them quickly. So much time would have been required to remove and re-set the guides that it was desired to leave them in place. These requirements led through several stages to the final design shown in the photograph and drawings.

The new shaft is six inches wider than the old, to allow the forms to be set back far enough under the wall-plates to provide for the thickness of the forms and bracing.

It was necessary to use the shaft so quickly after the

THE MIXER PLANT.

concrete was poured that it was thought best to cast reinforced concrete beams to which the guides could be attached. These were built into the partitions of the skip-compartments, but between the other compartments they stood open across the shaft, with their ends only imbedded in the concrete walls, and formed the whole support of the guides. They were held so strongly by the heavy mass of unset concrete that the far from passing skips only settled them more firmly into place, and the initial 'set' of the concrete was not broken.

The forms in the skip-compartments are in two halves, each made of a large side-plate and two hinged wing-plates that extend to the guides. They are tied to each other by iron straps passing behind the guides, to which they are fastened by counter-sunk screws; and to prevent their shifting, nails are driven through holes in the straps into the guides after they are lined up. Forms in adjoining compartments are tied together by bolts passing through pipes cast in the partition-walls, which serve to space the wing-plates properly.

The cage-compartment forms are somewhat different. Similar side-plates are used, but there are no wing-plates, and they are braced apart by angle irons spiked to the guides, which reach across the shaft in the 10-in. space below the reinforced concrete dividers. There are no concrete partitions, and the side-plates in adjoining compartments are connected by narrow hinged plates which block off the concrete, but permit it to project $2\frac{1}{2}$ in. in vertical columns under the reinforced concrete dividers, as additional supports for them.

The end form is composed of three large plates attached by hinges. The side plates have projections to core out slots in the walls, in which planks or timbers may be set to support platforms and ladders, pipes or power cables. The end plate was built in two parts, afterward riveted together, to get it behind the pipes and cables already in the shaft.

The forms are 5 ft. 9 in. high, and overlap the 5-ft. section of concrete by 9 in. Bolts, or bent iron rods threaded, project through properly spaced holes in the forms $7\frac{1}{2}$ in. below the top, and are imbedded in the concrete when it is poured. When the forms are stripped and raised, the short ends projecting from the concrete fit into corresponding holes 5 ft. lower in the plates and $1\frac{1}{2}$ in. above the bottom. Thus, when raised, they are supported and held firmly at the bottom, where the greatest pressure from the concrete exists. The upper part is brought into alignment by attachment to the guides. They are therefore self-aligning, and require no tedious adjustment to plumb-lines swinging in the shaft.

It will be noted that all hinges are made with tapered pins that may be driven entirely out, thus disconnecting the plates, and that the hinges which are situated in the beveled corners are made so that in the skip-compartments the narrow wing-plates, in revolving, turn directly away from the face of concrete, and cannot bind. The side-plates then have ample end-clearance, and can be moved straight out also without possibility of binding.

The form in each compartment could be stripped and raised independently of the others. They were only tied together after being put in place and aligned by attachment to the guides.

The forms were made of heavy plate with accurately fitting hinges, and being very stiff, and firmly held at the bottom by the bolts cast in the walls, resist the pressure of the concrete without twisting or throwing too heavy a strain on the guides. They were made with great accuracy, all holes being drilled to template. The hinges were of beveled cast-iron, and were machined to standard by the use of jigs and templates, and the taper-line pins were turned in a lathe. This unusual care was taken so that parts could be replaced without special fitting.

With the exception of part of one set, which stood in the shaft from March until October, no new forms were needed, and with the exception of the forms in the skip-compartments, which are more or less battered by spillage from the skips, they are still serviceable.

Chute-mouths were passed by blocking off the concrete from the sections to be left open.

At the stations, partition-walls were cast in between the cage-compartments and between the cage and pipe

was placed upon them to keep the shaft straight. Then, four to six sets of special hangers were inserted at each point of work to hold the timbers securely above the break between timbers and concrete. These were made of $\frac{3}{4}$ -in. square bars, with a turnbuckle in the middle. The ends were bent, and reaching around the wall-plates, clamped them together. This was much more rapid than if customary hangers were used.

Each cage or skip was equipped with a complete outfit of tools, etc. These consisted of two pairs of half-ton chain-blocks for each compartment, axes, saws, wrenches, tamping-bars, grease for the forms, rope-lashing, etc.

The shaft was divided into three nearly equal sections, and the starting-points were selected where the ground broke large, with a smaller section below. After hardening, the concrete would therefore wedge itself against the ground and support itself. In each case, it was necessary to make special timber-supports for the wet concrete, which made the first sections rather slow.

In beginning, each form was set with the top about two feet below the bottom of a set of timber. This was to leave only a short space of ground unprotected in the interval before the next section was poured. Owing to changes in form-setting when working past levels, this did not always remain the same, but it was found later that considerable space could be left without danger. When set as originally planned, the guides were unsupported for only a very short distance, and the attachment to the concrete beams was so close to the set above that there was no unusual strain on the guides, and little

ELBOW AND DISCHARGE-PIPE.

compartments. The edges of these walls facing the stations were formed of reinforced concrete pillars 5 in. wider than the partitions and 10 in. deep.

CONCRETE DIVIDERS AND GUIDE ATTACHMENTS. The reinforced cast beams for dividers were 10 by 10-in. sections and 6 ft. 2 in. long. They were cast in steel forms near the collar of the shaft. The concrete was mixed in a 4-cu. ft. power-mixer. After standing for a few days on the casting-plates, they were lifted by a small hand-derrick and stored in piles for three to four weeks, to season before use.

The guides were bolted to cast-steel brackets, which were fastened to the concrete beams by bolts passing through them, and can be replaced if damaged. Guide-bolts can also be changed easily, and there is sufficient height in the slot to allow for errors in boring guides or variations in the height of the beam. No attempt was made to have the ends of the guides meet on the brackets. Splice-plates were strapped on the back to hold temporarily until they could be permanently secured. Bent cover-plates were placed over the brackets to make pockets in the concrete, so that guide-bolts or the brackets themselves could be replaced.

METHOD OF WORK. Before concreting was begun, the guides were aligned carefully, since entire dependence

FORMS SET UP, SHOWING CONCRETE DIVIDERS AND ANCHOR-BOLTS.

on the green concrete.

The operation soon fell into a routine, which was not altered except in speed. Work began at 7:00 a.m. The skips and cages were then loaded with tools and current supplies, including a set of reinforced concrete beams. Upon reaching the point to be concreted, the hangers were taken out, the guides disconnected from the dividers, the wall-plates cut in three pieces and dropped away from the set above, after which the whole set of timbers came apart easily and was dropped into the skips or piled on the cages and lashed securely. The shaft was then cleared of loose rock and the 'muck'

dropped into the skips or stored on the cages; line material went down the shaft. In some cases, the ground was not sound, and lacing was needed to hold it temporarily in place. This was usually cast into the concrete and left. It had to be held such a short time that loose ground was easily handled, although not so rapidly.

As soon as the timbers were removed and the faces cleaned, chain-blocks were hung above and the concrete dividers slung between the guides close under the timber dividers, and lashed to them with ropes. Each set of blocks was then hung over one of the large side-plates of the forms, the slack taken up, all bolts in the forms removed and the forms themselves loosened. They were then hoisted 5 ft., slipped over the upper bolts projecting from the concrete and fastened loosely. The tie-plates behind the guides were then attached and spiked, to centre the two halves of the form. The spacing-bolts between adjoining forms were put in and the forms connected from end to end of the shaft. If there appeared to be a slight tendency to get out of square or line, they were wedged into position from a convenient point of ground, and all bolts were tightened. Other wedges were put in against the ground, and between guides and skips or cages, to take up the pressure of the fresh concrete, which might spring them out of line.

The surface of the forms against the concrete were then painted with a light grease to prevent their sticking, and they were ready for the pour.

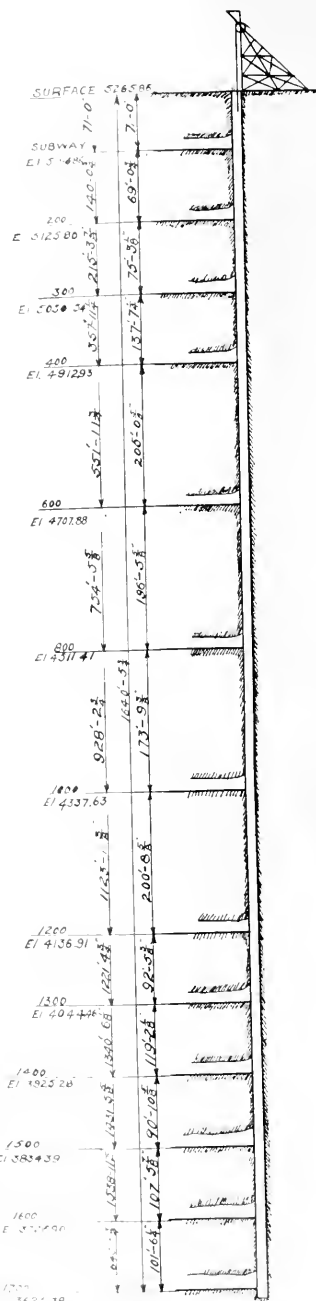

When the forms were first put down, it was found that the bottom part of the form, which overlapped the concrete when raised to a new position, could not be put in without a great deal of trouble. A form taken away from a face of concrete cannot be replaced in its original position, and the slight irregularity between the bottom and top of the form exaggerated the difficulty. By riveting a $\frac{1}{2}$ -in. plate 10 in. high around the top, a sufficient recess was cast to give plenty of clearance, and made changes rapid.

During the month of June, it took about 81 minutes to take out the timbers, and $47\frac{1}{2}$ minutes to raise the forms and connect them ready for concreting.

The elbow was then attached to the concrete column, the 6-in. pipe laid across the shaft to the skip-compartments, and concrete pouring began from that end. The first one or two batches of concrete were made richer and wetter than the rest. As the concrete rose nearly to the top of the forms, the reinforced concrete beams were dropped in place and attached to the guides by means of the brackets. This lined them up with the guides, and the concrete was then tamped around them closely and brought up flush with the top of the forms.

The average thickness of the side walls was about 15 in. The thin section and all partition walls were reinforced, and reinforcing bars were laid across the ends of the concrete dividers to tie them into the side-walls.

As soon as the skip-compartments were finished, the opening between the skip and cage compartments was planked up temporarily, and if it was a set having a window, the permanent planks were put in also. The battens removed from the set taken out were inserted

Station Elevations

THE SHAFT STATION ELEVATIONS.

above and the skip-compartments were ready for hoisting ore. The other compartments were finished later, and the pipe connected for the next section.

A convenient time was used for going to the top for 'lunch,' after the forms were set, for instance, or in some cases, after the round was finished. The timbers were then taken from the cages and skips. When com-

The mixture was rather rich, however, and the concrete was not injured.

The men employed in the shaft were 12 in number; 2 in each compartment, one pipe-man and one foreman. Since every set was, in its essentials, like every other, and each pair worked in the same compartment continually, they became extremely expert in the work, and in co-

operating to make progress. Some work a little out of the routine had to be done in changing concrete-pipe, compressed-air connections, or the pipes and cables in the shaft. This was done whenever convenient, ordinarily during the latter part of the shift. An electrician was usually in attendance.

CONCRETE MIXING. The mixing, which includes bringing the cement and aggregate from storage to mixer, occupied a crew of eight men. One man measured rock and sand into the hoppers; four men trammed it to the mixer; one man assisted in dumping the cars and measured the cement into the hopper; another tripped the materials into the mixer and measured the water, and a foreman fed the mixed concrete into the hopper and 4-in. pipe. This required considerable care. Mixing began when a red signal lamp was lighted from below, and stopped when it was turned off. After the section was poured, the concrete mixer and pipe were washed out with water, so that they might be clear for the next day. When not mixing concrete, the men cast reinforced dividers, removed timbers, and cut it to lengths for use underground. Others

CAGES EQUIPPED FOR WORK. THE PUMP ATTACHED TO THE CABLE.

ing up after finishing a round, the boxes containing bolts, tools, etc., were at once overhauled to see that the equipment was complete for the next section.

The 70-ft. section above the adit-level was concreted by discharging the concrete into a car on the nearest cage, and hoisting it to the collar. From there, it was spouted down to the forms.

It was at first expected that the concrete would stand about 64 hours before the forms were stripped, but when greater speed was made, a number of forms were stripped in less time, and during the latter part of the time, a few forms stood only about 20 hours after pouring.

unloaded cars of sand or rock and elevated it to the bins, trammed cement to the mixing station, or assisted in operating the ore-conveyors.

PROGRESS. It was originally estimated that the maximum time for putting in a section would be ten hours. This time dropped at once to eight, and as the men became more accustomed to the work, it was still further reduced, until it became a question of how to use the rest of the shift to advantage. Additional production was desired, and hoisting usually began as soon as the skip-compartments were free. The men from the skip-compartments loaded the skips, operated the belt-con-

voyers, etc. The time occupied in doing effective work outside the shaft was charged to that work and not to the shaft. Those men not occupied in loading skips or operating the conveyor-plant, made what preparations were possible for the next round. Before long, the time was shortened so much that it was possible occasionally to concrete two sections in eight hours. This first occurred on November 14. Later, two sections in eight hours was frequent, and in June, 260 ft. of shaft was lined in 30 days, and 64,545 tons of ore hoisted in the same time. On July 3, three rounds were put in.

PROGRESS TABLE

1915	Days worked	Number of feet	Dry tonnage hoisted
October	11	55	27,844
November	22	135	63,491
December	12	90	74,313
1916			
January	19	110	67,000
February	29	150	66,166
March	31	165	75,190
April	30	200	63,820
May	30	250	69,247
June	30	260	64,545
July	27	205	62,722

An accurate log was kept of all shaft-work beginning on November 6, 1915, and covering 1540 ft. of shaft. During this period, the average time required to complete a cycle of operations in putting in a 5-ft. section was 6 hours 14 minutes. In June 1916, it only took 4 hours 31 minutes for the average set.

	November 6 to July 30, minutes	June, minutes
Loading tools and cleaning shaft.....	30	19.2
Removing timbers	98	80.9
Raising and setting forms	84	47.4
Connecting concrete pipe	28	27.3
Mixing and pouring concrete.....	78	60.0
Unloading cages and cleaning tools.....	17	14.8
Miscellaneous delays	9	3.4
Lunch	30	17.3
	374	270.8

COST OF CONCRETING SACRAMENTO SHAFT

	Total cost	Cost per foot of shaft
Miscellaneous preparatory expense:		
Making platforms, etc., for cages and skips	\$ 252.79	
Changing power-cables, electric lights, etc.	263.00	
Supply-house at shaft.....	120.05	
Miscellaneous	527.68	
	\$1,193.52	\$0.72554
Aligning guides	557.55	0.33893
Routine labor in shaft		
Removing timbers	\$5,063.08	
Raising and setting forms.....	4,998.21	
Pouring concrete (\$9.686 per yd.)	1,303.65	
Repairing and changing concrete columns and other pipe-work.	2,318.22	
Protection and changing of power cables	1,655.43	
	18,338.59	11.1481
Concrete	12,796.47	26.016
Concrete dividers	3,663.32	2.227

	Total cost	Cost per foot of shaft
Miscellaneous supplies:		
Reinforcing bars	\$1,150.25	
Guide-brackets and covers.....	3,024.77	
Bolts	718.02	
Angles for partition-walls.....	461.91	
Distance-plates	482.24	
Miscellaneous	3,512.57	
	\$9,349.76	\$5.684

New guides, ladders, etc:

Labor	\$1,527.91	
Timber	675.90	
	2,203.81	1.339
Hoisting engineers	1,861.15	1.131
Supervision	3,372.10	2.050
Accident compensation	88.53	0.053

Total	\$83,424.80	\$50.712
Credit for timber delivered to mine department	2,801.62	1.703

Net cost	\$80,623.18	\$49.009
Cost of opening quarry and equipment of crushing plant	5,666.18	

CONCRETE

	Yards of material	Yards of concrete in place	Cost per yard of material	Cost per yard of concrete in place
Rock and sand				
Quarrying and crushing 7,800	6,195		\$0.8978	\$1.1204
Transportation and elevation at storage-bins.....	7,800	6,195	0.1729	0.2177
Cost of storage-bins.....	7,800	6,195	0.2713	0.3416
	7,800	6,195	\$1.3420	\$1.6898
Sand and rock bought for experimental section...	93	75	1.641	2.035
	7,893	6,270	\$1.346	\$1.6939
Cement		21,559.98		3.4386
				\$5.1325
Mixing		3,363.69		0.5594
Concrete column, elbows, air-lines, etc.		2,435.79		0.3885
Forms		4,672.66		0.7452

Cost per yard of concrete delivered at forms*

\$6.8256

*There was no absolute method of measuring the concrete in place. It was estimated by casting several batches composed of the regular mixture of rock, sand and cement, into a box, and measuring the contents of the mass after it was set. The mixer-charge was estimated to make 11 cu. ft. of concrete in place.

REINFORCED CONCRETE DIVIDERS

	Total cost	Per cu. yd. concrete
Labor of mixing	\$1,168.54	\$5.02
Rock and sand	393.73	1.69
Cement	962.82	4.13
Reinforcing	727.13	3.12
Pipes for bolt holes	185.55	0.80
Forms	90.00	0.39
Miscellaneous supplies	135.55	0.58
	\$3,663.32	\$15.72

The costs include all items chargeable to this work. As the cages and skips made only 3 trips per round, no charge was made for power. The engineer only was

charged to the work, since it is necessary to have one hoisting-engineer continually at his post.

Estimates were made on a scale that would have paid the shaftmen \$4.50 per shift. The work was done, however, on a much higher scale, the average rates prevailing being given herewith:

Shaftmen	\$5.47
Pipemen	6.22
Electricians	5.22
Mexicans at quarry	2.40
Mexicans mixing concrete, etc.....	2.90

MEN ASSOCIATED WITH THE CONCRETING OF SACRAMENTO SHAFT
George Mieyr (master mechanic), in charge of all operations.

C. S. Heisler, in charge of quarry and mixing plant.

F. M. Heidelberg, draftsman, designer of forms.

Joe Lutz, in charge of work in shaft.

B. W. Pernel, shaft and pipe man.

William Gunn, in charge of electrical work.

Carl Carlson, Alex Jacobson, Dan Murphy, Charles Mieyr.

Pat Smith, Sam Granquist, W. B. Hughes, George Kelly, W. R.

Drew, John Johnson, shaftmen.

Frank Craig, in charge of mixing crew.

There were no changes in the personnel from the beginning of the work, and it was an excellent example of what can be accomplished with team-work and goodwill.

The Separation of Galena From Blende by the Horwood Process of Flotation

By Allan D. Rain

*The Horwood process bears the name of its originator, E. J. Horwood, assistant general manager for the Broken Hill Proprietary Company, at Broken Hill, Australia. Briefly, the principle of the process as applied to mixed lead-zinc sulphide ores is that advantage is taken of the different oxidizing temperatures of galena and blende, the galena oxidizing to lead sulphate much quicker, that is, at a much lower temperature than the blende oxidizes to zinc sulphate (given, of course, the ore of a fineness that is necessary for separation of the lead and zinc particles). Such being the case, by judicious roasting of a mixture of these two minerals the lead sulphide can be totally or superficially oxidized to its sulphate under control temperature without affecting the zinc sulphide. By a subsequent flotation operation, the blende may be recovered in the ordinary way and the lead sulphate or the sulphide coated with a film of the sulphate that, not being amenable to flotation, remains as a residue. It may be better, before dealing with the process on a commercial scale, to give a description of the method of making laboratory tests.

PREPARATION OF THE ORE. On all ores treated to date, it has been found that the material must be screened through an 80-mesh sieve. Generally speaking, this ought to be considered the maximum of coarseness, and for close recoveries of either zinc or lead, the finer the material the better for the process.

SULPHATIZATION. The success of the process depends on the manner in which this is done, the object being to preferentially sulphatize the galena, leaving the blende unchanged. By keeping the ore at a low temperature for the first portion of the roast, and then raising the heat toward the latter portion (provided the material is kept freely stirred the whole time) no difficulty will be experienced in the laboratory, in changing the galena and leaving the blende unaltered. It is obvious that at no time during the roast must the temperature be raised

sufficiently high to oxidize the blende. Should this happen, however, the final object of the process will not be defeated, but the resultant zinc loss (due to the solution of any oxidized compounds in the acid used for subsequent flotation) would be increased. The increased quantity of zinc thus lost is directly proportional to the amount of oxidized or sulphatized zinc produced during the roast.

Generally speaking, the temperature to be maintained during the roast should increase from 400°C. at the start to about 500°C. at the end. Some ores require a longer roast than others, the time being dependent on the nature of the sulphides present, and the degree of comminution of the ore. It is not necessary to completely sulphatize the whole of the galena in order to separate it from the blende. The degree to which sulphatization should be carried is to some extent dependent on the size of the ore particles. In order to deaden the galena to flotation it is sufficient to convert the surface of the particles into sulphate, the core of such particles remaining unchanged. The only method of ascertaining definitely when the sulphatization has been carried sufficiently far is to take portions of the roasted ore and make laboratory tests on them, carefully weighing and assaying the products so obtained.

If laboratory tests are made prior to sulphatization on a large scale, and the lead sulphate determined in the sulphatized material, this will afford a simple and rapid method of determining when, in actual practice, the roast has been carried sufficiently far. Then, for example, assuming that in the laboratory the lead sulphide had been sulphatized to the extent of 78%, and that such material gives the desired results, all that is necessary in roasting a bulk lot of ore is to withdraw a sample every quarter of an hour from the furnace and determine its lead sulphate contents, this determination not taking more than a few minutes. For instance, a sample of zinc-lead slime sulphatized in the laboratory over a gas-burner for about two and a half hours was found to

*Abstract from *Copper Topics*, published by the Braden Copper Co., Chile.

contain 73% lead as sulphate; the subsequent separation made on this material yielded approximately an 86% zinc recovery and an 81% lead recovery in zinc and lead concentrates respectively. A small amount of zinc is lost invariably in the subsequent flotation, by reason of the formation of soluble zinc compounds during the roast; but if the roast has been carried out in the correct manner, the quantity of zinc so lost should not amount to more than at most 2 to 3% of the total zinc in the ore.

FLOTATION. Fifty grams of the sulphatized ore is weighed and placed in a 500-cc. cylinder, provided with a stopper. Boiling water is admitted to the 250-cc. mark, then 3 cc. of 95% sulphuric acid (Sp. Gr. 1.8376) and the mass is agitated for a short time. After this, either 0.1 cc. or 0.2 cc. of oleic acid is added, and the whole is then thoroughly shaken by hand. The agitation is continued until the sulphides become thoroughly oiled and float to a large extent. The contents are then transferred to a 16-oz. beaker and the bulk increased with boiling water that has been used to rinse the cylinder. The beaker is then placed on a sand-bath and flotation is produced by heating the bottom of the beaker. A little calcite is added prior to the application of the heat, to prevent the material from lying dead on the bottom and to assist the flotation. During flotation the mass in the beaker is stirred gently with a glass rod in order to hinder the formation of too large clots, which include floured lead sulphate. The concentrate is removed with a spoon from the top of the liquor, the skimming being continued until no more blende floats. The lead remains in the residue as sulphate.

The concentrate resulting from the above first separation is usually dirty; it requires to be re-agitated in a 1% sulphuric acid solution (without the addition of any further oil) and re-floated in a manner similar to the first separation. The float concentrate resulting from this re-agitation is transferred to a tin-can, dried, the oil burned off, and the residue weighed. The residue resulting from the two separations are bulked, transferred to a tin-can, dried, and weighed.

METHOD OF TREATMENT BY ZINC CORPORATION. After a number of successful laboratory demonstrations, trials more closely approaching commercial treatment were made on large parcels, with encouraging results. Almost the first to become interested in this process, besides the originator, E. J. Horwood, was the management of the Zinc Corporation, which had as a by-product a small proportion (roughly 5 to 6% of total concentrate produced) of a mixed lead and zinc slime, for which it could neither secure sale nor devise any means of successful separation. This process was tried as a probable solution of their metallurgical difficulties, and one by which they could separate into salable products this mixed lead-zinc slime-concentrate. This they were stacking with a view to some successful treatment later. The mixed slime concentrate assayed approximately 35% zinc, 16.5% lead, and 25 oz. silver per ton.

A glance at a representative buyer's formula will ex-

plain why this product was unsalable as a zinc concentrate.

Buyer's price on board cars:

$$(Zn - 8)(P - 5\%) + (Pb - 8.5)(30c.) + (Ag - 5 \text{ oz.})$$

$(P' - 2) - R$, where

Zn = % of zinc.

Pb = % of lead.

Ag = oz. silver per ton.

P = average price of zinc over six months following delivery.

P' = average price of silver over six months following delivery.

R is the smelting charge, which is \$24 when the price of spelter is \$84, and increases 72c. per ton for each \$4.80 increase in the average price and decreases 72c. per ton for each \$4.80 decrease in that average price. A penalty of 30c. per unit is imposed for every unit of lead over 8%, but the penalty is never to exceed payment for the silver.

THE STEEL INDUSTRY is expanding. New construction which will be completed during the calendar year will add to the yearly capacity of the Steel Corporation 1,100,000 tons, and 1,500,000 tons to the capacity of independent plants. Projects for construction in 1917 indicate further increases in annual capacity of 1,900,000 and 700,000 tons, respectively, for the Corporation and the independents. Thus, in 1916 and 1917 the capacity of the industry, apparently about 40,000,000 tons per year at present, will be increased about 15%. The last period of new construction of steel plants ended in 1913. To supply raw material for keeping existing steel plants in operation at their present rate, 60 million tons of iron ore must be brought eastward from the mines about Lake Superior. The movement of such an amount of ore in the nine months during which navigation is open on the Great Lakes requires utilization of the ore-carrying fleet to its utmost capacity.

COKE OVENS of the sort that save by-products such as the coal tar which is the raw material of dyes, pharmaceutical preparations, and explosives, were little used in the United States before the European war made them important and profitable. Statistics gathered in another connection by the Bureau of Mines indicate that at the end of 1915 there were thirty-eight active plants of by-product ovens and that these plants are so extensive that they employed two-thirds as many men—13,000—as the old-fashioned bee-hive ovens. The by-product coking plants already built in 1916, or definitely planned, will add about two thousand ovens. Two plants, of 204 ovens apiece, completed in August, will make about 140,000 tons of coke per month.

STEEL WORKERS are now receiving the highest wages known. Iron puddlers receive \$8.80 per ton, and as a day's "turn" is 2½ tons, a puddler is making at the rate of \$22 per day. Hot weather prevents more than 4 days a week being worked, according to *The Iron Age*.

Flotation Concentration of Carbonate Ores

By Joseph T. Terry, Jr.

As a pioneer in, and a contributor to, the successful concentration of carbonate ores by the flotation process these notes may be of interest to the mining and metallurgical fraternity.

My friend O. C. Ralston of the Utah State University has written lucidly on this subject and therefore there is no need to reiterate the information disclosed in his excellent article, which was given publicity in a recent issue of the MINING AND SCIENTIFIC PRESS, but rather enlarge upon it.

Sulphide filming of copper and lead carbonates is commercially accomplished by the use of soluble sulphides, such as the sulphides of soda, or calcium and hydrogen sulphide gas. The sulph-hydrates of soda, calcium, and ammonium are exceedingly effective in causing true sulphide filming of the carbonates, but unless used in very small amount or removed by washing the pulp, seriously interfere or prevent the flotation of the filmed mineral.

Hydrogen-sulphide gas is the most satisfactory reagent and can be cheaply produced without the use of acids by the destructive distillation of numerous organic substances mixed with sulphur. This method of production offers a cheap and effective reagent for precipitating copper from acid-leaching solutions.

Sulphide filming of the carbonate minerals is best accomplished by introducing the gas into the ore-pulp crushed to -80 mesh, with a density of about 20% solid, kept in motion or agitation in an enclosed agitator, or other suitable apparatus, and subsequently subjecting to flotation under the same conditions as a natural sulphide-pulp.

In attempting the flotation of ores containing both natural sulphides and sulphide-filmed carbonates, failure to float the natural sulphides is due to what may be termed the 'wetting' action of the soluble sulphide reagents on the natural sulphides. I discovered that this can be readily avoided or overcome so that both sulphide-filmed carbonates and natural sulphides are floated simultaneously.

The sulphide film on lead carbonate is exceedingly firm and may be accomplished by introducing the sulphide-filming reagent into a ball-mill in which the ore is ground.

The film on copper carbonate is not firm and readily scoured, hence the necessity of sulphide-filming after the ore has been reduced to a pulp.

It is therefore evident that the pneumatic or Callow cell is the more satisfactory in which to accomplish the flotation of copper carbonate. When the impeller type of cell, such as the Minerals Separation apparatus, is used in concentrating copper carbonate, successive film-

ing treatments becomes necessary to secure a high recovery, except in the case of slime, but my experiments indicate that the grade of concentrate produced is considerably higher than from the pneumatic apparatus.

In concentrating sulphide-filmed lead carbonate the impeller type of flotation-cell yields excellent results, and the scouring action is less apparent. When copper carbonate ore is reduced to a colloidal slime before sulphide-filming and flotation in the impeller type of cell, the scouring action due to the violent agitation is not manifested, and a high-grade concentrate with excellent recovery is possible without repeated sulphide-filming treatments. I am not prepared to state the physical and mathematical law governing this condition, but foresee an interesting problem in the realm of physics and colloidal chemistry for those qualified to solve it.

It must not be construed that all copper carbonate ores are susceptible to concentration by flotation. I have encountered several instances where the mineral was so intimately associated or combined with the gangue that neither a satisfactory recovery nor a good grade of concentrate was attainable. However, there is a vast tonnage of copper carbonate ores in the Western states that is amenable to the sulphide-filming flotation process.

Copper and lead carbonates in combination with iron oxide do not yield a high-grade concentrate, as much of the iron oxide is filmed and floated.

It is a noteworthy fact that oxide of tin (cassiterite) is particularly susceptible to sulphide-filming and flotation, yielding both a clean concentrate and a high recovery. This is due to the crystalline nature of the mineral.

GASOLINE extracted from natural gas during 1915 amounted to 65,364,665 gal., valued at \$5,150,823. There were 414 plants operated, California having 20, Illinois 16, Ohio 50, Oklahoma 63, Pennsylvania 139, and West Virginia 114. The average recovery of 'gas' per 1000 cu. ft. of natural gas was 2.57 gal. The 1915 output was a gain of 53%. There was also an increase of 7% in the number of plants.

NATURAL gas production of the United States in 1915 amounted to 628,578,842,000 cu. ft., sold for 16.12c. per ft. Domestic consumers paid 28.32c., and industrial concerns 9.7c. per 1000 cu. ft. The output is 6% greater than in 1914. West Virginia produced 244,004,159,000 ft., Pennsylvania 113,691,690,000 ft., Oklahoma 87,516,753,000 ft., and California 21,891,035,000 feet.

THE MT. BOPPY MINE, the largest gold producer in New South Wales, Australia, treated 6336 tons of ore in August, yielding \$40,000.

Mining Method at Inspiration

By George R. Lehman

*The Inspiration company's method of mining is one of the so-called caving-systems, whereby the ore is caused to cave and crush itself thus reducing to a minimum the blasting and handling. It is a modification of the method introduced by Felix McDonald at the Ohio Copper Co.'s mines in Utah, and was put into operation at the Inspiration under his supervision. The method consists, essentially, of under-cutting the ore (taking out a horizontal slice), allowing the ore above to cave and crush, and drawing off the crushed material through small inclined raises driven under the caved ore, into main inclined raises that lead down to the haulage-drift chutes.

PRELIMINARY WORK. By referring to the accompanying illustration a good understanding of the method will be obtained.

After shafts have been sunk, the haulage-drifts are driven under the ore of the section or sections to be mined at intervals of 100 ft. as shown in Fig. 1. These drifts are of large size, being 9 ft. wide at the base of the rails, $7\frac{1}{2}$ ft. wide at the cap, and $7\frac{1}{2}$ ft. high above the rail-base. Where timbered, the above refer to inside-timber dimensions.

After the haulage-drifts are completed, or during their driving, 'pony' sets are erected every 25 ft. along the drifts. The pony set is about 5 ft. high, placed on top of the regular drift-set and is the place from which the car-loaders operate the chute gates discharging into the haulage-cars.

Inclined raises are then started from the pony sets at an inclination of from 50 to 54°, depending on whether the sub-levels are to be 30 or 35 ft. vertically apart, in a plane at right angles to the haulage-drifts. When these raises are up from 10 to 15 ft., chutes are built at the pony sets and ore-gates of steel are installed.

The raises are then advanced until the first sub-level is reached. Sub-drifts are then started from the first raises to reach the required level, and are driven parallel with the haulage-drifts. These drifts break into the other raises every 25 ft. as they advance. The raises are again advanced to the next sub-level where drifting is to start. The drifts as they advance connect with the raises. All of these development-raises are about 4 ft. diam., and the sub-drifts 6 by 7 feet.

This method of raising and sub-level drifting is continued until the height is reached where the first under-cut is to be made, and the drifts are driven as before to connect with the raises.

The first under-cut sub-level will be started below the top of the ore, at the height at which it is intended to cave. When the preliminary development is finished, the sub-level drifts on the first under-cutting level are 50 ft. apart, as they are on the 'sub' just below, as shown in Fig. 1. On all the 'subs' below, the drifts are 100 ft. apart. All the drifts on each 'sub' are also connected with inclined raises every 25 ft. Cross-drifts, connecting all the drifts on each 'sub,' are also driven at intervals of about 150 feet.

FIG. 1. PRELIMINARY DEVELOPMENT DRIVING INCLINED RAISES FROM HAULAGE-LEVEL DRIFTS.

The next work, before under-cutting is commenced, is to drive on the level to be undercut other sub-drifts, between and parallel with those already driven, making the drifts on this 'sub' 25 ft. centre to centre. These drifts, as they advance, meet branch raises of the main inclined raises at $12\frac{1}{2}$ or 25-ft. intervals as desired. These small branch raises are called 'finger raises,' many of which are put up just before or ahead of the undercutting operations.

UNDERCUTTING the ore is accomplished by starting at a cross drift, on the boundary of the section to be mined, and in retreating from that cross-drift, drilling deep holes, nearly at right angles to the drifts, into the pillars between them, and blasting out the ground. Three holes are drilled in each side at different angles in the same vertical plane, with one hole in the back of the drifts, thus making seven holes to the ground. For this work a water hammer one man drill with large steel is used. The holes are from 8 to 10 ft. deep. Usually the

*Excerpt from paper presented at Arizona meeting of American Institute of Mining Engineers (September 1916).

rounds are blasted one at a time, the under-cutting receding from the caved ground.

Ore from the under-cut is drawn through the finger raises, in each of which has been built an ordinary board chute to control the drawing. The finger-raise chutes are placed about 4 or 5 ft. below the sub-level so that they will not be blasted in shooting the under-cutting holes.

While in some ground, the ore begins to cave as soon as under-cut, in hard ground it does not start until the under-cutting has receded a considerable distance.

ORE DRAWING. After the ore caves it is drawn as desired. Large boulders that will not pass the raise-chutes are blasted. In drawing the ore, the 'chute-tappers' work in pairs. One 'tapper' goes up a raise, from the 'grizzly sub,' which is the first 'sub' below the under-cutting level, opens a chute-gate and draws the

For hoisting ore, two main shafts 101 ft. apart are used. Both shafts have three compartments, of which two in each shaft are skip-ways. The third compartment in one shaft contains the ladderway, pipes, and electric conduits, while in the other shaft the third compartment contains an Otis double-deck elevator for hoisting and lowering men. The shafts, underground bins, and stations are all lined with reinforced concrete.

Only two levels are used for hauling ore, the 4th and 6th. The vertical distance between levels is 130 ft. An idea of the arrangement of the mine is obtained from Fig. 2. On the 6th level the shafts are connected by two drifts, one for each shaft. In each drift there is a tippie over the bin at the shaft. The arrangement of the drifts, bins, tippies, and stations is symmetrical with a centre line between the two shafts so that the tippies are operated by one man from a central point.

FIG. 2. ARRANGEMENT OF MINE LEVELS AND RAISES UTILIZED IN INSPIRATION CAVING SYSTEM.

ore, while the other tapper works the ore through the grizzly on the 'sub' below.

All grizzlies have about 1-ft. openings and are made of timber or steel rails. They are placed over all raises on the 'grizzly sub' and are set at right angles to the drift. Pieces of ore too large to pass are broken with an 8-lb. hammer by the tapper tending the grizzly.

After passing the grizzlies, the ore falls into the main raises and down to the haulage-drift chutes where it is loaded into 5-ton cars and hauled in trains, of 15 to 20 cars, to the shaft-bins.

The second under-cut can be started at one, or any number of sub-levels below the first under-cut, according to the height of ore that it is desired to cave. It could begin at the bottom of the ore if desired. In fact, the first under-cut could start at the bottom of the ore if it were known that the orebody to be mined could be caved throughout its total height.

HAULAGE AND HOISTING. At the Inspiration mine the ore-trains are hauled by compressed-air locomotives. Arrived at the shaft the cars are emptied into the shaft-bins by barrel-shaped tippies, five cars at a time. From the shaft-bins the ore is loaded automatically into 12½-ton skips and hoisted by electrically-driven automatic hoists to the steel bins on the surface.

On the 4th level one double-track drift passes between the two shafts and is connected to the shaft-stations by a small cross-drift. The ore is emptied by one tippie, on this level, into a small bin, which is connected with the 6th-level bins by a concrete-lined inclined raise. This arrangement makes necessary only one loading-level for the skips.

The Inspiration Consolidated Copper Co. commenced underground development on a large scale toward the latter part of 1913 but did not start regular mining operations until August 1915. The tonnage mined gradually increased as the concentrator was able to handle it until at present (June 1916) an average tonnage of 16,700 tons is being mined daily.

The cost of mining is now 60c. per ton, including 20c. for development and all fixed charges.

The percentage of ore and copper extraction obtained by this method cannot be determined positively until some section has been entirely mined from top to bottom of the ore. Based on results in six sections of the mine from the first under-cut to the capping estimated to contain 1,886,450 tons, and which has been almost completely drawn to capping, the ore extraction is 102.44% and the recovery of copper 86.52%. The second under-cut is expected to increase the copper recovery.

The Institute Meeting

By Charles F. Willis

For the first time in 15 years the American Institute of Mining Engineers has honored Arizona by conducting its annual meeting within its borders. It was a belated recognition of the growing importance of Arizona as a mining region. The New York delegation numbered 35, others joining the party at Albany and points in the Middle West. At Chicago they were entertained by the local section, many of whom joined the party. Attached to the train was the private car of Ben. B. Thayer, past-president of the Institute.

On the way to El Paso the engineers were given an opportunity to study the geological conditions and mineral resources of the country through which they were passing and its environs by the use of a geological map presented individually to the members by Carl Scholz. At Kansas City, the party was joined by the Missouri delegation, which included Philip N. Moore, presidential candidate, and D. A. Buchler, State Geologist of Missouri.

El Paso was reached the next afternoon. The visitors found a fleet of automobiles awaiting them for a passing inspection of the many local points of interest. They visited first the mobilization camps of some 90,000 troops stationed outside the city, and the border patrol. Some of the party went to Juarez, Mexico, where a bullfight was witnessed. Toward the end of the day the party was taken through the great smelter of the American Smelting & Refining Co., Karl Eiders conducting them and explaining the metallurgical methods. Keen interest was shown in the basic converter and the casting system in use at this plant. At 7 o'clock a Mexican dinner was offered by the El Paso members of the Institute, during which a Mexican orchestra provided music. Following the dinner, L. D. Ricketts proposed a rising vote of thanks to the hosts, this being acknowledged graciously by Mr. William W. Rose. The party entrained at 11 o'clock for Santa Rita and Hurley.

It is reported that three engines and all the 'dinkies' in the State were necessary to push the heavy train to the Santa Rita mines. The result was duly accomplished, and when the Chino Copper Co.'s men had sufficiently recovered from their astonishment at the appearance of the long steel snake, an explosive serenade nearly convinced the delegates that Villa had preceded them. The early morning was spent in inspecting the big open cuts, the interest of the engineers being especially caught by the crushers and steam shovel methods. Following this visit automobiles carried the party to the mills of the Empire Zinc company, which demonstrated new magnetic processes that many of the visitors had not seen before. A ten-mile automobile run through a part of the valley now opened by prospectors com-

pleted the morning program. Returning to Santa Rita the engineers found a barbecue awaiting them.

Upon arrival at Hurley, the visitors, in small groups, spent two hours in a study of the methods of the Chino mill. To many members this was the first introduction to the flotation process, the magnetic separator, and the Garfield tables. All Hurley was ready for the delegates, and refreshments and entertainments were provided until 11 o'clock, when the train left for Douglas. It was generally agreed that the day in New Mexico had been a revelation of Western hospitality.

At Douglas, under the guidance of Messrs. G. H. Dowell, A. V. Dye, Forest Rutherford, and a corps of assistants composed of the heads of departments, the visitors were shown over the big smelter of the Copper Queen Consolidated. As they started on their tour they were given booklets describing the plant in detail. From the power-house, through the converter-building, to the reverberatory-building, the roasters and the storing-yard, where thousands of dollars' worth of copper in bars is stacked, the excursion was led.

Promptly at 10:45 the delegates boarded the train for the Calumet & Arizona smelter, where another tour awaited them. Through the mill and sampling plant, with their wonderful conveyor-belt system, to the ore-beds, where charges are automatically mixed, then to the acid plant, which will have an ultimate capacity of 200 tons of sulphuric acid daily, the crowd streamed. Here they watched the lead-burners lining one of the mammoth tanks with sheet-lead, while above them the structural-steel men were riveting and higher still a force was building the roof. Then the main smelter-building, with its reverberatory furnaces, blast-furnaces, converters, and finally the molding department, were visited.

Luncheon was served near the main building. To say that it was enjoyed is putting mildly the feelings of those who had taken the long walks necessitated by a full view of the plants. The artillery band played a concert for an hour, when the excursionists took the train to Douglas to attend the first serious session. This was held in the Y. M. C. A. building, which had been decorated for the occasion. Dr. Ricketts, president of the Institute, announced that he would temporarily relinquish the chair to Walter Douglas, who acted as chairman.

The chair called on John C. Greenway, general manager for the Calumet & Arizona Mining Co. to make the address of welcome. This Capt. Greenway did in a graceful manner in behalf of the local chapter of the Institute and the people of the State. After devoting a short time to the pleasant task of making them welcome,

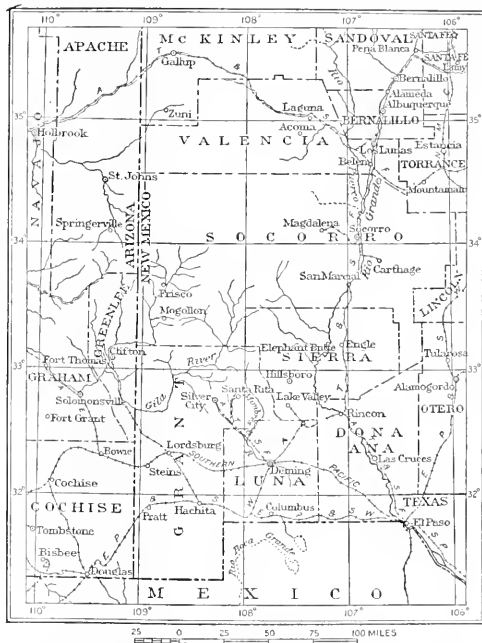

the speaker told the members of the Institute in some detail the program for the remainder of the week. Mr. Douglas called on Dr. Ricketts to respond, but the latter saying that he was a host like the rest of the Arizonians, asked Mr. Thayer, of New York, to reply. In doing this, Mr. Thayer paid a beautiful tribute to James Douglas, who, he said, had done more for copper mining than any other individual. He also offered the suggestion that the people of Arizona should honor the man whose handiwork is to be seen in practically every smelter or concentration plant in the State by naming a lively town after L. D. Ricketts. This suggestion was received with much applause.

The schedule of arrangements for the remainder of the trip was then read by the Secretary, Bradley Stoughton. Mr. Douglas requested that after each paper on the afternoon program had been read, the interesting points brought out should be discussed for five-minute periods by as many of the delegates as felt inclined to do so.

A. C. McGregor, designer of the C. & A. plant and the Arizona Copper Co.'s plant at Clifton, read an interesting treatise on 'Features of the New Copper Smelting Plants in Arizona.' Dr. Ricketts led the discussion, saying that the advance in smelting lies in the prevention of loss. He then discussed the loss of 0.7% copper at the International smelter at Miami. E. P. Mathewson, superintendent of the Anaconda smelter, commended the local smelters for their cleanliness of operation and congratulated the designers of Arizona plants. A paper by F. N. Flynn, superintendent of the Arizona Copper Co.'s smelter, was then read. The absence of L. O. Howard necessitated the reading of his paper, 'The Basic-Lined Converter in the Southwest,' by the Secretary, Mr. Stoughton. This precipitated a great discussion. Mr. Douglas told of one converter-lining in the Old Dominion smelter that had produced more than 70,000,000 pounds of copper before it had to be replaced. Mr. Mathewson discussed the comparative merits of the Smith-Pierce and Great Falls types of converters at some length. Kuno Doerr, general manager for the A. S. & R. at El Paso, made a brief talk along the same lines.

'Determination of Dust-Losses at the Copper Queen Reduction Works' was the title of a paper read by J. Moore Samuel. Dealing as it did with the recovery of metal that formerly had passed out of the stack as smoke, the paper brought about a discussion of a vital subject. Mr. Douglas discussed it briefly, being followed by Mr. Mathewson, who said that the methods employed by the Anaconda smelter to abstract the value from fume were somewhat similar to those of the Copper Queen, and compared such extraction with methods of treating flotation-concentrate. The recovery from fume at Anaconda had materially reduced the damage done to farms in the surrounding district, he said, and the company had been upheld in this contention by the courts, which had found that the resultant loss to farmers was negligible. He then called attention to the importance of choosing a good site for a smelting plant, as

a poor one would result in almost certain damage to the surrounding country, while a good site would save much unpleasantness. Sidney J. Jennings, Vice-President of the Institute, discussed the same topic and suggested that considerable loss is made at the smelting plants in the South-west by reason of the high winds, which carry the dust away. Mr. McGregor said that the C. & A. probably suffered loss from its ore-beds owing to the high winds, and with that fact in view, the ore-beds had been housed. Mr. Douglas pointed out the fact that at

SOUTH-WESTERN NEW MEXICO AND PART OF ARIZONA, WHERE THE
ENGINEERS VISITED.

the local smelters ores averaging 6% are treated, while the Miami concentrate averages from 30 to 40%. Dr. Ricketts agreed that in all smelters means should be taken to prevent ore dropping through the air. It should all be hoisted, and a hose could be used to wet it, so as to prevent dust. The men need not go in the houses while the ore-beds were being filled. He expressed the belief that such precautionary measures would pay. He also discussed the Cottrell system, which he had found to reduce the loss in fume to almost nothing.

Following the adjournment of the afternoon session, many of the delegates took motor-cars over the district, visiting the camps of the regulars and militia-men in this vicinity, also crossing to Agua Prieta.

The night session opened with a large crowd in attendance, many mining men not on the excursion taking this opportunity to hear the papers and discussions. H. W. Morse was the presiding officer. The first paper read was that of the chairman and H. A. Tobelman, on leaching tests at New Cornelia. Mr. Morse read the

paper and then with the aid of stereopticon views, showed several of the methods of leaching that had been tested at Cornelia and found successful. For a time he was bombarded with questions from all sides. 'The 2000-ton Leaching Plant at Anaconda' was the title of a paper by Frederick Laist and H. W. Aldrich; this was read by Mr. Mathewson, and discussed in some detail by him. F. N. Flynn and others asked a number of questions regarding technical points. Secretary Stoughton read the treatise on 'Possibilities in the Wet Treatment of Copper Concentrates,' prepared by Lawrence Addicks of New York. Mr. Morse and several others discussed this phase of leaching. A. G. McGregor, in an address on the 'New Copper Smelting Plants in Arizona,' told the engineers that in Arizona during the past five years there had been more activity in copper-smelting plant-construction than in the same length of time in the history of the world. Mr. McGregor said that in this period five new smelting plants had been constructed and put into operation; the monthly output from these plants averaged from 5,000,000 to 18,000,000 pounds. He then described new problems that had been solved successfully, and new features in plant design and equipment that had been developed. Following adjournment, many of the delegates went to the Country Club to attend a reception and dance given in their honor; this was largely attended by Army people and residents of the district.

At Bisbee the following day the visitors were met by a brass-band and 50 automobiles, which carried them around the district. Many went underground through the mines, while others remained on the surface. The Bisbee sessions were full of good things.

The State of Missouri and not the eastern coast-line should be the site of the proposed Government munitions plant, according to H. A. Buehler, State Geologist of Missouri, who spoke at the Bisbee session. Mr. Buehler supported his contention by a summary of the mineral resources of Missouri.

A further handicapping of the chemical industries and the paint and dye manufacturing interests of the country, due to a lack of manganese ores, was predicted in a paper by E. C. Harder of the U. S. Geological Survey. Mr. Harder explained that even at the beginning of the European war there had been a great decrease in imports of both ores and alloys of manganese, and that since 1914 the price had risen from \$37 to \$100 per ton, with ferro-manganese still higher. He said: "The situation in the United States at the present time regarding the supply of manganese ores and alloys of manganese is one of great seriousness and is likely to become increasingly so while the War continues. The dependence of the country upon foreign countries for this supply is being forcibly indicated."

Other papers attracting attention were 'The Geology of the Warren Mining District,' by Y. S. Bonillas, J. B. Tenney, and Leon Feuchere; 'Co-operative Effort in Mining,' by Joseph P. Hodgson; and 'Gold and Silver Deposits in North and South America,' by Waldemar

Lindgren. In this paper Dr. Lindgren stated that the South American mineral resources in precious metals are less than those of our continent and that even progress and enterprise will be unable to raise its production to approach the figures attained by North America.

At the close of this session the visitors were banqueted at the Country Club, after which they proceeded to Globe, arriving on Thursday morning, the 21st. During the morning the party visited the mines and reduction works of the Old Dominion Copper Mining & Smelting Co., and were greatly impressed. The afternoon and evening were reserved for the discussions of subjects relative to mining in the Globe district. It was at these meetings that the engineers discussed the means for developing the flotation process.

Chief among these conclusions was the prediction that the flotation process is now in its infancy and that with the discovery of new flotative agents further development is assured. The afternoon meeting was marked by the first public presentation of a report of experiments on several miscellaneous wood-oils. A statement concerning these oils was presented in a paper by Glenn L. Allen, of the Shattuck Arizona Copper Co., and O. C. Ralston, of the U. S. Bureau of Mines.

Rudolf Gahl, of the Inspiration Consolidated Copper Co., rendered the afternoon meeting memorable by his account of the history of the flotation process at Inspiration. Dr. Gahl told of the exhaustive research and experiment of his company in an effort to develop the flotation process, and pointed out that the vast expenditures demanded for this experimentation had been made to pay for themselves by the results achieved.

Mining and smelting constituted the general subject of the evening session. This evoked an interesting discussion on the methods of fighting mine-fires, with especial reference to the plenum system. At the close of the evening an illustrated description of the Cottrell process was given by G. A. Schmidt.

Globe saw the ending of the full meeting. While the greater number went by automobile the following day across the Apache trail and by the Roosevelt dam, others went directly to their homes and offices. The trip over the historic Apache trail was both pleasant and instructive. Excellent opportunity was offered for geological observation, while those whose interests were chiefly mechanical, found much of interest in the Roosevelt dam and the power-houses which furnish the power for Globe and Miami. At Phoenix more of the party left, bound particularly for properties in which they were interested, and which were out of the line of travel. A number left for a side trip to the Ray Consolidated Copper Co., at Ray and the mill and smelter at Winkelman.

METAL EXPORTS from the Malay States, south-eastern Asia, during the first half of 1916 were as follows: gold, 8074 oz.; tin, 260,000 tons; and wolfram, 186 tons.

RAILROAD MATERIAL EXPORTS in the year ended June 30 totaled \$74,729,000, over double those in the previous period.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

JOPLIN, MISSOURI

REDUCTION IN SURPLUS ORE AND PRICE OF POWDER.

Renewed activity in the ore-market has resulted in the disposal of a large part of the surplus concentrates which have acted as a depressing factor during fully six months. There is more optimism felt than for weeks. The previous week started the ball rolling, and the momentum gained by the first of this week was such that a heavy tonnage of low and medium-grade zinc-blende was purchased, the price ranging from \$5 to \$10 per ton above the levels that have prevailed for three months. This buying movement coming at the same time as the attempt of ore producers to curtail the output voluntarily, and the probability of a coal strike which would force the closing down of many mines for lack of power, has created a much better feeling, and has brought hope that the disturbing element of concentrate stocks might be wiped out before the beginning of winter. There is a possibility of reduction in the cost of dynamite. For some mines the cost of powder has been prohibitive, and as old contracts expired, forcing these companies to buy in the open market. Properties in the sheet-ground and low-grade disseminated district thus have been forced to suspend operations. Sixty days ago a large number of these old contracts expired, and that time marked the cessation of activities of a considerable number of the heaviest consumers of dynamite in the region. The powder companies have reduced the cost of powder \$2 per 100 lb., and also lowered the price of caps slightly. While this reduction averted the closing of some of the mines, it was not a sufficient cut to make any material difference to the majority. An announcement this week in a semi-official way, by N. P. Rood of the Hercules Powder Co., states that there would be another reduction in the price of powder, one of the largest factors in the cost of mining, probably before the first of the new year. The decreased price of powder, with the lower price being received for zinc-blende, brings back into the production list a large number of sheet-ground producers who have been forced to close. This change in the price of powder would give relief to the distressful labor conditions, as so many mines are closed resulting in many miners being out of employment or working half-time. Some of the miners have left the field, and in this way relieved the situation to a limited extent.

MEXICO CITY, MEXICO

NEW DECREE AFFECTING MINING OPERATIONS.

After the usual preamble that occupied more space than the decree itself, the following appeared in a Carranzista newspaper published at San Luis, San Luis Potosi, about September 14:

ARTICLE 1. All grantees of mining concessions must work there-upon, under penalty of their forfeiture if such work be suspended for more than two months continuously, or for more than three months interruptedly, during each year.

ARTICLE 2. Any grantee having a good excuse for not working may solicit of the Secretary of Fomento the corresponding permission. This can be granted only in case the reasons submitted be well founded and proven, and for a period not to exceed three months, unless at the expiration of this period there still exists a cause rendering absolutely impossible any operation; in which event, such further time as may be deemed strictly necessary can be given.

ARTICLE 3. The Secretary of Fomento, duly considering the cases presented by the owners of mining concessions, shall designate for each of the new concessions, as well as for each of the old ones not yet exploited, the number of laborers which, as a minimum, must be employed thereon, taking into account the number of claims of each concession.

ARTICLE 4. The mine-owners who may have had, or may have, their properties under exploitation, must employ the same number of men that have been or were employed at the time operations were suspended, the Secretary of Fomento reserving the right, in view of the allegations submitted by the mine-owners, to change this number according to the necessities of the case.

ARTICLE 5. Whenever the Secretary of Fomento declares forfeited any mining concession, he shall immediately bring

said declaration to the notice of the Secretary of Hacienda, in order that the latter decide whether the annulled concession shall thence-forward be open to public denouncement, or be worked and operated under the auspices of the Nation, in which latter event, he shall appoint a person for its management in the continuation of the corresponding work.

ARTICLE 6. This law shall take effect from the date of its publication.

National Palace, Mexico, September 14, 1916.

(Signed) V. Carranza.

SUTTER CREEK, CALIFORNIA

STRIKE SITUATION.—OLD EUREKA, HARDENBERG, and ROSE MINES.

The following notes were written on October 1:

The strike situation remains apparently unchanged. Ben Goggin, general organizer of the Western Federation of Miners, has issued a statement to the effect that the Union is not demanding recognition of its organization, and states that the men are willing to return to work when they receive an increase of 25c. per day, with the assurance that Union men will not be discriminated against, because of their membership or participation in the strike. Nothing is being said about the reported demand for shorter hours, or to have the employee's time begin and end at the collar of the shaft, instead of at the working face in the mines. The Union claims that the mine-owners have never been asked to recognize the organization, and that if the 25c. increase be allowed on the above

understanding, an agreement will be signed by which members will refrain from making further demands for a period of two or three years, or such further time as may be agreed on. Business-men in this region are feeling the effects of the strike, and it is estimated that since the men went out on September 19, they have lost over \$40,000 in wages. The mines and plants remain uninjured, with the exception that pumping expense and repair work is kept up without the revenue from gold won. The owners claim that their properties are well prepared for this situation, and that by means of proper attention to underground conditions the mines will be in as good condition six months from now for the resumption of work as they are today. They claim that 1200 of the 1500 miners of Amador county are quite willing to return to work on the old basis, but apparently the owners wish to avoid disturbances and annoyances likely to result if the strikers are replaced with other men, so no move has yet been made toward that end. The only mill at work in the county is that of the Plymouth Consolidated.

The Old Eureka shaft has been unwatered to a depth of 700 ft., and thoroughly repaired from the surface to that point. Tracks are now being laid from the new modern saw-mill to the collar of the shaft for the convenient handling of supplies. Grading for the new steel hoist is progressing well, although the present low wooden structure will doubtless remain in use for some time. A new double-drum hoist has been ordered.

The machinery at the Hardenberg mine on the Mokelumne

ing has occurred so far. In the south end of the district all of the mines are closed, except the Amador Consolidated, (Old Eureka), although a few men are employed on repairs at practically every mine. I am informed that a few hundred men, probably as many as 400, have left the district since the strike was called. This will certainly have the effect of leaving the mines short-handed when they are ready to resume. It is claimed by the Western Federation officers that none of the Union men have left the district, but well-informed people claim that this is not true. They say that a large number of Union as well as non-union men have taken their departure. So far there have been few acts of violence, and the offenders have been taken in hand by the Sheriff, who shows strong determination to do his duty without fear or favor. He has appointed a number of extra deputies, including some from the ranks of the Union and expresses himself as determined to prevent violation of the law, whether by miners or mine operators. Naturally there is in this respect, a feeling of confidence that there will be no serious violence.

TORONTO, ONTARIO

SUMMARY OF MINERAL OUTPUT FOR HALF-YEAR.

Returns of production for the first six months of 1916, made to the Ontario Bureau of Mines by the metalliferous mines and works of the Province, are summarized in the following table, which also gives comparative quantities and values for the corresponding period of 1915:

Product	Quantity		Value	
	1915	1916	1915	1916
Gold, ounces	173,021	235,060	\$3,570,972	\$4,822,740
Silver, ounces	11,101,909	10,267,743	5,188,763	6,188,269
Copper, pounds		77,795		14,368
Cobalt (metallic), pounds		121,817		103,677
Nickel (metallic), pounds		13,933		5,899
Molybdenite (concentrates), pounds		12,631		13,975
Cobalt and nickel oxides, pounds	141,500	401,408	56,812	204,638
Copper in matte, tons	8,523	11,426	1,704,600	2,285,096
Nickel in matte, tons	15,182	20,651	7,591,000	10,325,766
Iron ore, tons	134,977	80,698	288,296	243,268
Pig-iron, tons	225,940	295,349	2,856,040	4,424,496

river, 31 miles south of Jackson, was re-started during the week. A new cable is now being installed, and the work of unwatering and repairing the shaft at this old producer will soon be under way. The property has been taken over by the W. J. Loring Co. The men interested in the Hardenberg mine are Americans, and the present deal is said to include other valuable mining ground in that vicinity. The Hardenberg is equipped with a 20-stamp mill, electrically-driven hoist, and a well-timbered, double-compartment shaft.

San Francisco people have been here inspecting the Rose mine, which is about a mile east of Sutter Creek. This property is owned by L. R. Poundstone of Colusa county, and has been worked irregularly during the past 40 years. Recently the mine was equipped with a 20-stamp mill, compressor, small hoist, and has been opened by two shafts, which the owner has kept unwatered since the cessation of operations some months ago.

AMADOR CITY, CALIFORNIA

THE STRIKE SITUATION FROM ANOTHER CORRESPONDENT.

There is no change in the strike situation, except that the Keystone mill, which was running a week ago, is now closed down. It is understood, however, that this is in accordance with a pre-determined plan which contemplates closing the mine for about 60 days for the purpose of re-timbering 300 ft. of the shaft. At Plymouth all is quiet and a full complement employed. There are rumors of possible attempts from the outside at interference with operations at Plymouth, but nothing

Production for the period ended June 30, 1916, shows a material increase in value of all metals over that for the first six months of 1915, with the single exception of iron ore.

GOLD. If the present rate of production is maintained, Ontario should reach the \$10,000,000 mark for 1916, compared with \$8,500,000 in 1915. Of the total yield, Porcupine contributed all, with the exception of \$545,434 produced by the Croesus in Munro township, the Roggon near Dryden, the Tough-Oaks at Kirkland Lake, and the Canadian Exploration Co. at Long Lake near Sudbury. The Hollinger Consolidated and Dome Mines are the largest producers at Porcupine. Before the year ends Boston Creek will probably be contributing to Ontario's gold yield. Development is proceeding on some of the more promising claims at Kowkash (situated east of Lake Nipigon) on the National Transcontinental railway.

SILVER. Since the beginning of 1916 the price of silver has advanced considerably, the average being 62½¢ per ounce—low 56½ and high 77½¢. As a result production has been stimulated, and the value, compared with 1915, shows a considerable increase. Although the quantity sold was less than for the corresponding six months of last year, the total output was greater, over 1,000,000 oz. remaining to be marketed. Undoubtedly the life of Cobalt will be prolonged as a result of introducing flotation treatment for low-grade dumps and slime. The Nipissing still leads in output with a value of \$1,766,561. The Mining Corporation of Canada—Cobalt Lake and Townsite City—is the next largest producer, followed by Kerr Lake, Coniagas, and McKinley-Barragh-Savage.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

CORVOA. For the sum of \$30,000 the Kennecott Copper Corporation has purchased the Wilson-Littles property on Latouche island. A considerable amount of development has been done, and the mine is well equipped.

VALDEZ. A preliminary report has been made by Pierre Bonery, manager of the Valdez Creek Placer Mines. A few days' sluicing in an old channel yielded gold worth \$20,000. As the power-plant was threatened by water it was removed. This gives plenty of dumping ground. The ditch has now a capacity of 3500 miner's inches of water. The face of the present gravel pit yields high by panning.

ARIZONA

CHLORIDE. The population of this centre is now 1200, and is increasing steadily.

GLOBE. With a capital of \$5,000,000, the Greater Ajo Copper Co. has been organized by Globe men. The property to be developed is in Yuma county, 100 miles from the Mexican border. A. B. Saling and others of Miami located 100 claims last April. The new centre is called Copperton. A. Reid is secretary and L. M. Greenstein engineer. It is said that the deposit could be worked by steam-shovels.

MIAMI. To develop 62 claims adjoining the Inspiration, Miami, and Inspiration Needles properties, the Miami Con-

LATEST PROPERTY MAP OF MIAMI, ARIZONA.

solidated Mines Co. has been organized with a capital of \$2,500,000. John S. Cook and others are behind the project. Two drilling experts have been engaged to prospect the ground.

CALIFORNIA

Oil production of the State in August totaled 294,457 bbl. daily, an increase of 1000 bbl. over July. Shipments from the fields amounted to 9,458,850 bbl., the largest for any month. Stocks declined 1,415,669 bbl. to 49,718,180 bbl. In the 10 fields there were 74 new rigs, 250 wells drilling, 51 wells completed, 2 wells abandoned, and 7071 wells producing. Crude-oil prices at the well, 14 to 18° gravity, were 63c. per bbl., and for 25 to 26°, 72c. per barrel.

ALLEGHANY. Development at the Plumbago gold mine is reported to be encouraging, keeping the mill working steadily. —Ten stamps at the Tightner are crushing ore from the mine, and five are crushing dump material.—The Rainbow Extension has been bonded.

CERRO GORDO. The Cerro Gordo Mines Co. of Inyo county has declared a dividend of 2½c. per share. When L. D. Gordon of San Francisco assumed control a year ago, and during three months of a lease he had previously obtained, just prior to operations on company account, he directed extraction of all available zinc ore. Since that time the company has paid-off an indebtedness of \$40,000, created a treasury reserve of \$50,000, paid its \$25,000 on the outstanding 1,000,000 shares, and paid for improvements costing \$15,000. The latter included a complete electric system to operate hoist and compressor, a warehouse at Keeler, and the covering of three tramway terminals. The gross revenue represented in these items is about \$120,000. The production of zinc and silver continues at the usual rate, and the management believes that the dividend rate may easily be maintained. Daily shipments are 50 tons by way of Mina and 40 tons through Owenyo. Last week high-grade lead ore was cut on the 400-ft. level, this shoot being the one opened at 200 feet.

COPPERPOLIS. Near this place the American Asbestos & Mfg. Co. of San Francisco is developing a large deposit of asbestos. The mineral is said to have a long fibre.

Construction of additions to the Calaveras Copper Co.'s mill is making good progress.

GRASS VALLEY. The Prudential mine has been sold by G. W. Root to F. M. Shideler of San Francisco, F. L. Rodgers of Connecticut, and others. An old shaft is down 750 ft., and a new one is down a good depth. It is probable that the Norambigua mine will be acquired also.

HART. A controlling interest in a new company to take over the Ore Belle Mines Co. has been secured by John Hays Hammond and others of New York. Two veins are being developed from a shaft 850 ft. deep.

IDRIA. The Panoche Valley Railroad Co., recently incorporated at Los Angeles, is issuing bonds to pay for a railway 52 miles long from south Dos Palos in Merced county to the Ashurst ranch in San Benito county. This line would pass close to the New Idria quicksilver mines, which are now 40 miles from any road, in mountainous country.

JACKSON. At the Kennedy tailing-dam an additional 25 ft. is being added by the firm that recently constructed the Argonaut dam.

MISKERSVILLE. Land on Stuart's fork in Trinity county belonging to J. C. Van Matre has been bonded to C. Mitchell and J. Bauer of Alaska. Drilling is to be done on the 650 acres, followed by dredging, if the land is valuable enough.

OROVILLE. Karl Brehme and a number of Los Angeles capitalists who are interested in the construction of the Slate Creek impounding dam have made application to the California Debris Commission to hydraulic ground owned by the company near St. Louis, on the Oroville-La Porte road. The Commission will no doubt grant the permit provided the dam is built to meet certain requirements.

PLACERVILLE. The chrome deposits of Hill & Hobler at Negro hill have been sold to the Noble Electric Steel Co. of San Francisco. The ore is hauled to Folsom by truck. The daily output is to be 25 tons.

COLORADO

BRECKENRIDGE. A syndicate headed by Bulkeley Wells of Telluride, and Leadville people, has taken over the Puzzle mine, an old producer. When new machinery is installed the shaft is to be sunk. The Puzzle Leasing Co. has been developing the Gold Dust mine for two years, and will continue its interest with the new owners.

CRIPPLE CREEK. The Vindicator Consolidated hopes to be treating ore by flotation in its new plant by November. This will deal with 350 to 500 tons daily, later on to be considerably increased. The mine contains large reserves of \$5 to \$8 ore suitable for this process. On No. 16 level the orebody is said to be 50 ft. wide, averaging \$30 per ton.

Fifteen sets of lessors are extracting rich ore from the El Paso Consolidated. The company has three machine-drills on exploration work.

DENVER. At Utah Junction, near Denver, the Ferro Alloy company is erecting two furnaces to reduce tungsten concentrate from the Rare Metals company's mill at Rollinsville, near Boulder, and make ferro-tungsten for the market.

LEADVILLE. Pumping, to unwater the Carbonate Hill and Graham Park districts through the Wolfstone and Greenback shafts, was started on September 27. Layne-Bowler pumps are working in both shafts. Water-level is at 1000 ft., and pumping will continue to a depth of 1120 ft. in the Wolfstone and 1350 in the Greenback.

At the Penrose pumping shaft the sinking pumps are being transferred to a station at the bottom of the shaft. The water-columns and cables are being assembled in one compartment, leaving two for hoisting. Preliminary work underground is almost complete.

Re-timbering of the Mikado shaft is finished to a depth of nearly 900 ft. Hoist foundations are being laid.

IDAHO

BOISE. The State inspector, Robert N. Bell, is authority for the statement that the richest discovery of gold quartz in the history of the State was made recently in an abandoned mine at Atlanta, 80 miles from Boise. The new shoot, 2 to 10 in. wide, has been opened for 250 ft. The ore is at a depth of 1000 feet.

BRUNER. During the half-year ended June 30, 1916, the Hecla Mining Co. made a net profit of \$766,887. This is \$295,135 more than the profit in the whole of 1915. Smelter receipts totaled \$1,979,211. Dividends absorbed \$650,000.

MULLEN. During the quarter ended June 31, 1916, the Federal Mining Co. shipped 38,972 tons of ore, returning \$624,029 net. The profit was \$268,287, a decrease of \$28,000 compared with the previous period.

On October 5 the Caledonia company paid 30¢ per share, equal to \$78,150. This makes \$755,450 for the year and \$1,638,181 to date. Net earnings in August were \$100,000.

In the Copper King mine, near Mullan, a diamond-drill has penetrated 17 ft. of ore containing from 5 to 10% lead and some copper. Drilling is being done 1100 ft. below the outcrop, and the bore was in 150 ft. before cutting the shoot.

MISSOURI

JOPLIN. Owing to a rise of \$1 per ton for calamine last week, shipments showed a gain of 500 tons. The output of the Missouri-Kansas Oklahoma region was 6525 tons of blende, 612 tons of calamine, and 750 tons of lead, averaging \$56, \$13, and \$70 per ton, respectively. The total value was \$157,433. The output for 38 weeks—\$24,800,193—is nearly that of the whole of 1915.

LINCOLN. In the central part of this State a new district is being developed, yielding an ore high in zinc-blende and lead, also high-grade baryte. A "Mother lode" is said to have been traced for many miles. Farmers have known of the deposits for years, but they never worked them to any extent.

The Saginaw Mining & Leasing Co., after nearly two years' pumping, has drained a 750-acre tract near Saginaw. This cost a large sum of money. Between 25 and 30 years ago the area was mined successfully, and has been popular with small companies. Work is carried on at a shallow depth, around 55 feet.

The Sutton, Steele & Steele company of Denver is trying to introduce its dry system of concentration into the Joplin district.

MONTANA

BUTTE. The Anaconda company has received 400 tons of high-grade zinc ore from its Douglas mine in the Pine Creek district of Idaho. This is to be concentrated, the product to be treated at Great Falls.—On the 800-ft. level of its Emma mine at Butte the Anaconda has cut 15 ft. of zinc ore. Regular shipments are made to the Washoe works.

Owing to shaft troubles the Butte & Superior August return was only 31,733 tons of ore yielding 7502 tons of zinc concentrate.

At the Butte-Duluth it is expected that the mill will be in operation within two weeks, treating 100 tons daily, in charge of George Desher. Leaching with sulphuric acid will be the first process tried. Acid is difficult to secure at present.

(Special Correspondence).—The Rothfuss-Dickmann company has received its transformer and is ready for power. The 10-stamp mill will be crushing in a short time. The owners have a large body of ore blocked-out in the Montana and Dalcourt mines, and a good quantity is on the dump for treatment.

It is reported that the old Elkhorn mine and the three large dumps of tailing, 250,000 tons, worth from \$2.50 to \$5, have been sold to the Walker interests of Salt Lake City, who will commence operation early in 1917.

The Elkhorn Bulwer mines are being overhauled. Driving proceeds at 200 ft. and ore has been struck. This mine produced \$10,000 worth of copper ore in four months from a winze 125 ft. deep, operated by a windlass. There is also a shaft 200 ft. from which a drift is being driven 60 ft. to a winze, that produced 10 to 15% copper ore. It was mined without the use of powder.

Workings of the Calumet mine have been overhauled and quarters erected for the men. This mine shows large bodies of lead and silver ore.

The Elkhorn Queen has been leased by a new party; it is an old producer of silver, lead, and gold.

The Golden Moss, a good gold and copper mine has been leased by C. R. Voreck, and development is being done. The gold ore is suitable for milling; the copper ore is of good grade. Elkhorn, September 23.

HELENA. From December 20, 1914, to August 15, 1916, the Franklin mine in the Scratch Gravel district produced ore worth \$242,517. The net profit was \$216,779.

RAIDERSBURG. The Black Friday Gold Mining Co. has arranged for Breitung & Co. of New York to operate its property.

NEVADA

According to Frank Manson of the Western Ore Purchasing Co., prospecting and development in this State has never been so extensive. There have been no startling discoveries, but the large output of ores and metals proves that preliminary work is bearing fruit.

GOLDFIELD. An option has been secured on the Kanrohat mine, 6 miles north-east of Round Mountain, by the Jumbo Extension company. The main adit is to be extended 150 ft. beyond its present length of 564 ft. A new 50-ton mill is ready for ore treatment.

The Diamondfield Black Butte company is to explore at depth with a core-drill having a capacity of 2000 feet.

Final figures of the Goldfield Consolidated's August return show that 17,300 tons of ore yielded a profit of \$18,211. Total

costs were \$7.43 per ton. Milling rose to \$2.68 per ton, and while the filter royalty was 1c., flotation royalty increased to 7c. per ton. Development cost \$8.39 per foot over 1664 feet covered.

MANHATTAN. Installation of a compressor at the Bath shaft of the Union Amalgamated has been finished, and the incline shaft is to be deepened 120 ft. Development at a depth of 500 ft. is reported as splendid. The mill is to resume treating mine ore this week. The Big Four and Seyler-Humphrey mines are sending ore to this plant.

ROUND MOUNTAIN. The Round Mountain company states that while the season's supply of water available for hydraulicking placer ground has been exhausted for some time, the management, by adopting new methods, has prolonged the earning period considerably by the introduction of several devices commonly used in building operations. Since the water cannot be brought to the gold-bearing ground, the gravel is hauled by teams and sledges, carried over a bridge, and dumped into the sluice-boxes. This part method of treatment has yielded the highest gold-content for the year. It was commenced early in August, and the total for that month was 2150 yd., with a gross value of \$2.08 per yard. Another small clean-up, made on September 12, yielded 871 yd. with a gross value of \$2.50 per yard. This process will be continued as long as practicable, and will add several thousand dollars to the gross earnings for the season.

TONOPAH. During August the Belmont produced 2232 oz. of gold and 199,445 oz. of silver, from 12,364 tons of ore. The profit was \$92,636. Diamond-drilling has been started in the East End mine, which the company is working under an agreement.

On October 21 the Tonopah Mining Co. pays 15c. per share.

The Jim Butler company's profit in August was \$24,296 from 4532 tons.

The Extension treated 9247 tons at a profit of \$64,506. The yield was 1649 oz. gold and 168,878 oz. silver.

NEW MEXICO

(Special Correspondence.)—High-grade ore was discovered last week at the face of No. 3 adit in the Eureka claim. The owner, D. E. Bearup, has already shipped a considerable tonnage from upper workings and this new shoot adds to the reserves. First-grade ore is being sacked for consignment to the El Paso smelter, while the second class will be treated at local custom works.

At the Pacific mine a large number of carpenters are rushing work on the loading-station and terminal for the aerial tram to the plant of Socorro company, at which latter point the terminal is practically completed. Mine development is being hurried, and the property will be in shape for supplying the tram with a regular tonnage for a long period.

The Eberle mine has been explored with a total of 600 ft. of sinking and raising and 1450 ft. of driving. Both the Queen and Deep Down veins run the length of the property, the former with a width of 4 to 18 ft. The Oaks Company's operations have been confined largely to the latter vein, and a good tonnage of mill ore is opened. Ore was shipped by this company during the development period, with a value exceeding \$2000 per ton. No stopping has been done.

The Mogollon company's output for first half of September was 1300 lb. of silver-gold bullion and 3 tons of high-grade concentrate, from treatment of 2025 tons of ore. A station at 900 ft. in the new shaft is being cut, and will be finished this week, when sinking will be continued.

A 1% dividend was paid on September 1 by the Socorro Mining & Milling Co., the fifth of similar amount this year.

Mogollon, September 19.

TEXAS

(Special Correspondence.)—An investigation into the coal and lignite resources of Texas has just been made under the

direction of the Bureau of Economic Geology and Technology of the University of Texas, and this data, in conjunction with that obtained in similar research by the State Mining Board, affords some interesting information. It is stated that there are, generally speaking, three coalfields in the State. They are known as the Pennsylvania in the north-central part, the cretaceous in Maverick county, adjacent to the Rio Grande, and the territory in Webb county, also bordering the Rio Grande. It is estimated that there are approximately 8200 sq. miles of known bituminous fields of which 5300 sq. miles are possibly productive. The total area, as shown by outcrops and actual development is about 60,000 sq. miles. Up to this time approximately 11,000,000 tons of lignite has been mined here. In the north Texas field the largest daily production of one company is 800 tons of coal. The estimated cost of placing coal on the surface is around \$2 per ton.

Austin, September 17.

UTAH

AMERICAN FORK. Probably no other district in Utah is having the development done by tunneling that is now going on in American Fork canyon, says the *American Fork Citizen*. The excessive snow-fall makes this system of exploration most efficient, besides having the advantage of cross-cutting the different formations and making it more economical to extract the ore when it is opened. The mountains are so precipitous that generally tunneling is a quicker method than sinking. At present the following properties are driving adits: Bay State, South Park, Miller Hill, Whirlwind, Dutchman, Texan, Smuggler, Utah Centennial, Mineral Flat, Red Cloud, Copper Glance, Atlantic, Pacific Extension, American Fork Queen, and Nash in the main canyon; the Belorophan, Miller Hill Extension, and Yankee in the Mary Ellen gulch; the Earl Eagle and Trinman in the Major Evans gulch; the Gold Hill, Mercer, North Star, Mary Elizabeth, Ella May, and Wasatch King in Silver Lake; and the Deer Creek Copper, Stewart, Silver Flat, and Alpine-Empire in the Deer Creek section. Besides these there are a number of others doing assessment work with adits, and several that are sinking shafts or taking out ore from the tunnel-level through winzes, drifts, and raises.

The Utah Power & Light Co. is to extend its transmission-lines to the Fissures Exploration Co.'s Pacific mine, and to the mill under construction on Dutchman flat in American Fork canyon.

FORTUNA. Some rich gold ore is being opened in the Paymal and Frazer mines, while encouraging results are reported from the Fortuna Independence, Fortuna Gold, Gold Queen, and others.

PARK CITY. The Daly Mining Co. is considering the erection of a 150-ton mill to treat lead-zinc ore and a large quantity of filling in old stopes. A hydro-electric plant at the mouth of the Ontario drainage-tunnel is also proposed. E. A. Wall is president of the company.

TINTIC. At the Iron Blossom the winze on the rich copper shoot is being sunk from the 1200 to the 1300-ft. level.

The Eagle & Blue Bell company is to sink from 1876 ft. to water-level, another 200 ft. or so.

A contract is to be let by the Tintic Standard for sinking its new shaft a depth of 1000 ft. Ore is being shipped, and new machinery is ordered.

WASHINGTON

REPUBLIC. A Consular Report gives the following note:

"Recognizing the increasing importance of the valley mining district in Stevens county, the Consolidated Mining & Smelting Co. of Canada has authorized a reduced treatment charge on ores that go to its smelter at Trail, British Columbia, and the Great Northern Railroad has also announced a reduction in the freight-rate, both schedules to become effective about October 1. The reduction rate will be \$1.50 per ton on ore that assays between \$25 and \$50 per ton, and the

freight will be \$2.45, or a total freight and treatment charge of \$3.95 per ton. If ore exceeds \$50 per ton, a proportionate additional charge will be made both on freight and treatment."

NORTHPORT. The Electric Point lead mine is now shipping 100 tons daily. Seventy men are employed. The carbonate ore averages 25%, and the sulphide 70% lead. To September 21 there had been delivered at Trail 2633 tons.

CANADA

BRITISH COLUMBIA

According to Lorne A. Campbell, retiring minister of mines for the Province, the mineral output in 1916 will be between \$45,000,000 and \$50,000,000, which is \$15,000,000 more than the record in 1912. This is largely due to increased prices of metals. Facilities for production have been increased greatly, and plants extended. A lot of new capital was invested and more is seeking an outlet. Labor has been scarce, resulting in labor-saving machinery being installed.

SLOCAN. According to Sidney Norman of Spokane conditions in the Slocan region are better than ever, although labor is lacking and treatment facilities are wanted for the zinc ores.

TRAIL. With a capital of \$1,000,000 the Coast Copper Co. has been organized with headquarters at this place to purchase and option claims and equipment of M. W. Bacon and W. E. Cullen of Spokane in the Quatsino district of Vancouver Island. It is said that the Consolidated Mining & Smelting Co. controls the Coast Copper Co. Recent development has proved extensive orebodies. The property is several miles from June landing on Quatsino sound, necessitating construction of a railway through mountainous country.

TRAVILLE. Butte and Spokane capital is largely interested in this district. This town is reached by wagon-road 10 miles long from the Grand Trunk Railroad, rising in elevation from 746 to 4000 ft. The principal properties are the Rocher de Boule, Highland Boy, Great Ohio, Amargosa, and Red Rose. The first is the largest producer, and is shipping chalcopryite ore regularly. A lower adit, 2700 ft. long, is being driven. D. J. Williams of Butte is manager. Litigation is hindering development at the Highland Boy. Prospects in the other mines are reported to be rather encouraging.

ONTARIO

CORALT. The Beaver Consolidated reports as follows for the quarter ended August 31: Bullion in storage, in ore, and bagged at mine totals 213,906 oz., against 294,183 oz. on May 31. Cash amounts to \$43,921, compared with \$92,184. Two shoots of high-grade ore were found at 400 and 460 ft. in the mine. The lower contact has been reached, and exploration continues on the 1600-ft. level. Tests with flotation are not definite yet. A property is being explored in the Kirkland Lake district.

KOREA

The August clean-up of the Oriental Consolidated was worth \$131,735.—The Seoul company treated 16,725 tons for \$143,319.

COPPER EXPORTS in eight months were as follows.

	1916	1915
United Kingdom	51,738	57,915
France	140,529	62,592
Holland	1,912	798
Italy	31,113	27,916
Denmark	1,901	1,550
Norway and Sweden	8,191	11,586
Russia	12,283	8,651
China and Japan	71	81
Sundries	2,634	1,597
Total	215,199	171,786

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

D. C. JACKLING has gone to New York.

COURTENAY DE KALB is on his way to New York.

J. H. SCHISSLER, formerly at Guanajuato, is here.

H. E. CRAWFORD was here from Los Angeles last week.

E. T. DUMBLE, of Houston, Texas, is at the Plaza hotel.

W. W. MEIN and W. KARRI-DAVIS visited Grass Valley this week.

F. LYNWOOD GARRISON is due to arrive at Philadelphia from Brazil.

F. E. MARCY has opened offices in the Atlas building, Salt Lake City.

HALLET R. ROBBINS has been at Copperopolis, in Calaveras county, California.

F. L. SIZER has been examining mines at Atlanta, Idaho, and is now in the Wood River district.

J. F. MAXNING and EDWIN W. MILLS, both registering from Korea, attended the Institute meeting.

HENXEN JENNINGS, who has spent three months in Alaska and California, has returned to Washington.

HARRY B. BARLING has returned to New York after a professional trip to several of the Western states.

WILLARD S. MORSE has gone to Chuquicamata, presumably to act as resident manager for the Chile Copper Company.

J. H. HOWARD, manager of the Amparo mines, and FRANK W. OLDFIELD, manager of the Cinco Minas, are returning to Jalisco, Mexico.

J. VOLNEY LEWIS has just returned to the East from a trip started on May 1 through the western mining states, British Columbia, and Alaska.

CHARLES E. PHOR, recently at Hedley, B. C., is on his way to Pachuca, Mexico, having accepted an appointment as surveyor at the La Blanca mine.

EDWARD H. BENJAMIN, W. KARRI-DAVIS, and HENXEN JENNINGS have been visiting the Mother Lode mines, motoring from Amador county to Mariposa.

Among the Montana members present at the Institute meeting were W. E. GARY, C. W. GOODALE, E. C. HICKMAN, C. R. KUZELL, E. C. POTTER, R. H. SALES, V. O. STROBEL, H. S. WARE.

EDMUND L. HAYT, for the past six years chief engineer to the Ray Consolidated Copper Co., has resigned to become assistant treasurer and mine manager for the Arizona Ray Copper Company.

KENNETH GUTTERMAN (Columbia '10), son of the late Franklin Gutterman, has been appointed secretary to EUGENE BRADEN, vice-president and local manager for the American Smelting & Refining Company.

At the annual election of the New York section of the Mining and Metallurgical Society, held on September 21, the following officers were elected: W. R. ENGALLS, chairman; W. Y. WESTERLUND, vice-chairman; and D. M. LIDDELL, secretary.

E. P. MATHIASON has resigned as manager of the reduction works of the Anaconda Copper Mining Co. at Anaconda to accept the position of general manager for the British American Nickel Corporation at Sudbury, Ontario, with headquarters at Toronto.

Among the Colorado men attending the Institute meeting in Arizona were the following: A. L. BLUMFIELD, D. W. BRUNTON, CHAS. A. CHASE, SUGRIDER FISCHER, JUSTIN H. HAYNES, V. G. HOLS, E. H. LAWS, P. M. McHUGH, JOHN C. TAYLOR, A. J. WERNING.

THE METAL MARKET

METAL PRICES

San Francisco, October 3.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	29.25
Pig lead, cents per pound.....	7.25—8.25
Platinum: soft and hard metal, per ounce.....	\$90—95
Quicksilver: per flask of 75 lb.....	\$75
Spelter, cents per pound.....	12
Tin, cents per pound.....	41
Zinc-dust, cents per pound.....	20

Antimonial-lead production of the United States in 1915 was 23,224 tons, valued at \$3,665,736. The antimony-content was 15.9%, and lead-content 84.1%.

ORE PRICES

San Francisco, October 3.

Antimony: 50% product, per unit (1% or 20 lb.).....	\$1.00
Chromite: 40% and over, f.o.b. cars California, per ton.....	13.00—15.00
Manganese: 50% (less than 35% metal not bought).....	14.00
Magnesite: crude, per ton.....	8.00
Tungsten: 60% WO ₃ , per unit.....	15.00—20.00

At Boulder, Colorado, tungsten is being bought for \$20 per unit.

New York, September 27.

Antimony: The quotation is unchanged at \$1 to \$1.10 per unit for ordinary ore.

Tungsten: Inquiries are more numerous from both domestic and foreign sources, but most of the buying is for export. Agents of the Allies are reported to be endeavoring to buy direct in the South American market, and business has been done in Argentina for export to France. Business with England is reported to be at a standstill, for the reason that the Minister of Munitions has fixed the price of ferro-tungsten at around 5s. 6d. (\$1.32) per lb., and of tungsten powder at 6s. 3d. (\$1.50) per lb., prices at which the American makers cannot do business. France, Italy, and Russia are paying a higher price for both materials. The quotation is unchanged at \$17 per unit.

EASTERN METAL MARKET

(By wire from New York.)

October 3.—Copper is strong, though quieter; lead is firm, spelter is closely held but fairly active.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending
Sept. 27.....	69.25
" 28.....	69.12
" 29.....	69.25
" 30.....	69.12
Oct. 1 Sunday.....	69.12
" 2.....	68.87
" 3.....	68.87

Monthly averages

1914.	1915.	1916.	1914.	1915.	1916.
Jan.	57.58	48.85	56.76	July	54.90
Feb.	57.53	48.45	56.74	Aug.	54.35
Mch.	58.01	50.61	57.89	Sept.	53.75
Apr.	58.52	50.25	54.87	Oct.	53.12
May	58.21	49.87	74.37	Nov.	49.12
June	58.43	49.03	65.04	Dec.	49.27

There is little to say regarding the silver market, the above quotations indicating steadiness. Purchases for India have been a feature in a market with restricted supplies. China exchanges showed signs of hardening, and exports from London tend to decrease. The present price is considered a reasonable one.

COPPER

Prices of electrolytic in New York, in cents per pound.

Copper dividends paid during September by 15 producers totaled nearly \$24,000,000. Utah Copper led with \$4,873,470, followed by Kennecott with \$4,166,367; Phelps-Dodge, \$3,600,000; Calumet & Hecla, \$2,000,000; Nevada Con., \$1,999,457; Chatoy, \$1,957,455; Calumet & Arizona, \$1,234,824; Ray Con., \$1,182,847; Copper Range, \$962,968; and Old Dominion, \$880,059. Nearly 12,000,000 shares will receive \$1.99 each.

Champion Copper has declared \$6.40 per share, making \$43.40 for the year. Miami pays \$1.50 per share on November 15. Osceola pays \$5 on October 31, North Butte 75c. on the 23rd, and Anaconda \$2 on November 27. The last amounts to \$4,662,500. Inspiration pays \$2 on October 30.

August outputs were as follows: Chino, 6,326,116 lb., Nevada Con., 7,688,014; Ray Con., 6,597,032; and Utah Copper, 20,315,440 pounds.

Tin is steady at 39.50 cents.

Eastern Metal Market

New York, September 27.

All ordinary features in copper were eclipsed by the closing last week of a contract whereby the Allies agreed to take 200,000 gross tons, or 448,000,000 lb., of electrolytic copper, delivery to be over the first half of 1917, at a price somewhere between 26 and 27c. The quantity represents about one-third of the United States production of the period. It is generally considered that the ultimate effect of this enormous purchase will be to steady the metal, inasmuch as it will take the Allies out of the market for months to come, and leave it to domestic influences. The copper that the neutral powers of Europe will buy will not count for much.

Zinc is quieter and lower, but ultimately it is thought that the Allies will buy extensively.

Lead has steadied around 7c., New York, the quotation of both the leading interest and the independents.

The inactivity in tin has disappointed sellers.

Antimony continues lifeless, with prompt metal at 11c., duty paid.

Aluminum is quoted at 62 to 63c. per pound.

COPPER

Late last week protracted negotiations were closed, and on Saturday, September 23, it was announced that Great Britain and her Allies had placed a contract with the leading American copper producers whereby the latter are to supply the Entente powers with 200,000 gross tons, or 448,000,000 lb., of electrolytic copper, delivery to be distributed over the first six months of 1917. Reports differ as to the price. In many directions it is persistently asserted that 26.50 to 26.75c., seaboard, is to be paid, but the reported total amount involved—\$120,000,000—indicates that the average price will be about 26c. With certainty it can be said that the consideration actually was between 26 and 27c. per lb. J. P. Morgan & Co., fiscal and purchasing agent for Great Britain, acted for the Allies, while the producers' interests are understood to have been looked after by John D. Ryan, of the Anaconda Copper Mining Co., and Joseph Clendenin, of the American Smelting & Refining Company.

According to the terms of the contract the Allied governments will take about one-third of the copper produced in the first half of 1917. Evenly distributed, exports on the contract will approximate 33,000 tons per month. To this quantity must be added that to be taken by the neutral powers, so that it is safe to predict that monthly exports in the first half of next year will break all records. The monthly exports averaged 22,559 tons in 1915, 30,919 tons in 1914, and 31,901 tons in 1913 the record year. In the first six months of 1916 exports totaled 147,913 tons, of which the Allies took 136,635 tons, and in the same period of 1915 exports were 136,527 tons, of which these Powers received 123,373 tons.

Members of the trade are of the opinion that the big contract will exercise a healthy influence on the market. They believe the elimination of the Allies from the situation for many months to come will steady the market, render it quiet, but strong, and make it possible for the domestic consumer to buy into the future without risk of serious loss. Should there develop an exceedingly heavy demand from industrial consumers the market might advance, but at present prices, further large buying for the arts of peace is not considered to be likely. Even at present prices there is a tendency to find substitutes for the metal. The combined buying of war contractors and industrial consumers has been heavy in the last week, the impending contract with the Allies having caused a rush to cover first quarter, and first half requirements, although less activity followed the announcement of

the big deal. Considerable variation in quotations continues. Those for electrolytic yesterday (September 26) were about as follows: Prompt, 29c.; October, 28.75 to 29c.; last quarter, 28; and first quarter, 27.25 to 27.75c. Lake is unobtainable for early delivery, the December position being quoted at 28c. The London quotation for electrolytic yesterday was £138, against £135 10s. a week previous. The Allies now have control of the foreign market. Exports from September 1 to 27 totaled 21,851 tons.

ZINC

Business tapered off in the early part of last week, and has since been spotty, with quotations on the downward trend. Early last week a few hundred tons were taken by Canadian buyers, but there is little else to report. Prompt was quoted yesterday at 9c., New York, and 8.75c., St. Louis, with last quarter ranging from 8.50 to 8.62½c., St. Louis. The trade is firm in the belief that the Allies will sooner or later come into the market for a large quantity in conjunction with the copper to be delivered over the first half of 1917. It is recognized that weeks or months may elapse before this business comes. Exports are heavy, those of September, up to and including the 26th, amounted to 10,591. The total exports in 1913, the last year preceding the War, in plates, sheets, pigs or bars, amounted to but 7783 tons. This quantity jumped to 61,802 tons in 1914, and 98,973 in the first 10 months of 1915. The spot quotation at London yesterday was £52, against £56 a week previous. Sheet zinc is unchanged at 15c. per lb., carload lots, f.o.b. mill, 8% off for cash.

LEAD

Whereas a few days ago independent producers were asking premiums of 5 to 15 points for prompt lead, they are now offering freely at 7c., New York, the quotation of the A. S. & R. Co. The leading producer asks 6.92½c., St. Louis, and independents quote 6.85c. Canadian purchasers last week took round lots of prompt and early delivery metal, and are still in the market, and this activity provides about the only feature of note at present. On the rise of the market consumers bought extensively, but stopped when independents endeavored to get over 7c. Meanwhile the market is quiet and steady. It is noted that consumption and production are fairly evenly balanced, and only a moderate demand will serve to impart strength to the market. Exports are proceeding at a good rate, amounting this month, up to yesterday, to 4416 tons. The London quotation for spot yesterday was £31 10s., against £30 15s. a week previous.

TIN

The heavy buying for which tin-brokers have been looking has not materialized, and they do not hesitate in saying that they are disappointed. On one or two days activity has been fair, as on September 21, when 100 tons changed hands, and the following day, when 300 tons was taken. The interest was almost entirely in future positions, some as far ahead as June, nearly metal being neglected. Banca has sold to a limited extent every day. Two reasons are vouchsafed for the inactivity of large consumers: one is that the tin-plate price for next year has not been fixed, and manufacturers are awaiting its adjustment; while another is that consumers accumulated reserve stocks a few months ago when the future appeared uncertain, and they are now using this metal. When buying does start, it would not be surprising to see a run-away market. The spot price for Straits tin yesterday was 38.6 c. On September 26 there was afloat 2960 tons, and up to yesterday 2750 tons had arrived.

Recent Patents

1,191,564. **ROCK AND ORE BREAKER.** Thomas W. Capen, Milwaukee, Wis., assignor, by mesne assignments, to Allis-Chalmers Manufacturing Company, a Corporation of Delaware. Filed June 27, 1910. Serial No. 568,990.

1. In a rock and ore breaker, an annular body, means for supporting said body to rotate on an axis at an angle to its axis of annularity, a head within said annular body forming with said body coating breaking elements, means for rotating said body on said axis at an angle to its axis of annularity, and means for moving one of said breaking elements relative to the other to cause their breaking surfaces to approach and recede from each other.

1,193,190. **CONCENTRATOR.** Clinton B. Ripley, Joplin, Mo. Filed Nov. 10, 1915. Serial No. 60,702.

1. In a concentrator, a longitudinally reciprocatory table-deck, stationary bearing sockets arranged near the ends of the table-deck, bearing studs connected with the ends of the table-deck and mounted to reciprocate within the bearing sockets, yielding means connected with the table-deck and serving to wholly support the same and hold the bearing studs up in slidable contact with the bearing sockets, and means to reciprocate the table-deck.

1,193,109. **FURNACE-BINDING.** James A. Bow and Peter Thill, Great Falls, Mont., and Archer E. Wheeler, London, England. Filed Dec. 17, 1914. Serial No. 877,707.

1. In combination with a furnace having an arched roof and supporting walls therefore, a series of buckstays distributed at intervals around the walls and terminating at the top of the walls, a fixed support, and flexible means carried by said support for maintaining the upper portions of the buckstays in permanent engagement with said walls.

In the week ended September 19, 610 patents were gazetted.

Company Reports

BLACKWATER MINES

This is the most important gold mine in the South Island of New Zealand. According to the general manager, V. Hartog, development amounted to 5000 ft. at a cost of \$12.97 per foot. Ore reserves are estimated at 91,251 tons, averaging \$11.23 per ton over a stoping width of 31.86 in. Mining cost \$3.32 per ton, including 38c. for hoisting and 8c. for pumping.

The mill treated 54,643 tons of ore, yielding \$8.60 per ton by amalgamation, \$1 by cyanidation, and 56c. from concentrate, a total of \$10.16 per ton. The recovery totaled 89.08%. The total value was \$115,611 (\$557,000). Costs were as follows: ore transport, 2c.; rock-breaker, 2c.; stamping, 26c.; tube-milling, 6c.; concentration, 4c.; cyaniding, 28c.; a total, with sundries, of 69c. per ton.

The year's profit was \$62,048 (\$298,000), of which \$120,000 was distributed in dividends. The credit balance is \$77,000.

ZINC CORPORATION

This company operates the South Blocks mine at Broken Hill, Australia, and buys and treats by flotation old tailing from the other mines. The zinc flotation plant was not operated on account of the War interfering with sale of concentrate.

Mine development consisted of 4932 ft., including 1548 ft. of diamond drilling. The main shaft is 1433 ft. deep. Reserves are estimated at 1,591,211 tons, averaging 14.8% lead, 2.5 oz. silver, and 9.2% zinc, an increase of 318,341 tons.

In 247 days the lead concentrating plant treated 154,628 tons of ore of almost the above average, yielding 31,397 tons of concentrate, 61.1% lead, 9.1 oz. silver, and 7.1% zinc.

The year's profit was \$675,000. Dividends were paid on common and preferred shares. The sum of \$480,000 was spent in buying shares of the Broken Hill Associated Smelters Proprietary.

WAIHI GOLD MINING CO.

The superintendent, E. G. Banks, of this, the largest gold and silver producer in New Zealand, in the North Island, reports as follows for the past year.

The principal work in the mine was in opening No. 11 level, on which 5577 ft. of development was done. This opened considerable quantities of ore. No. 4 shaft was sunk 171 ft. to the 1470-ft. level. Total exploration amounted to 17,681 ft. Ore reserves increased 230,043 tons to 673,896 tons. The Cornish pumps (Hathorn-Davey) lifted 85,945,450 gal., and the electric pumps 217,024,241 gal. of water. A turbine pump was installed on the 1309-ft. level. Seventy drills, mostly of the stoping-hammer type, are in use.

In the 200-stamp mill, 6 miles by rail from the mine, an average of 113,131 stamps and 7,925 tube-mills (total 11) reduced 192,333 tons of ore, averaging \$7.76 gold and 2 oz. 12 dwt. silver per ton. The residue contained 56c. gold and 9 dwt. of silver. The recovery value was 91.2%.

Concentrate assayed 9 oz. 19 dwt. 15 gr. gold and 49 oz. 2 dwt. 7 gr. of silver per ton. The extraction from this was 97.7%. There was melted 67,069 lb. of zinc-gold slime, yielding 531,190 oz. of doc bullion. The refinery produced gold 999.5 and silver 999.9 fine.

The year's revenue totaled \$363,679 (\$1,770,000). Cost totaled \$5.20 per ton, including office, taxes, fees, etc. Dividends (4 of 21c. each), totaled \$189,000. Investments at cost amount to \$1,820,000.

The hydro-electric plant, 50 miles away, costing \$941,000 generated 12,597,649 units. It operates on the Waikato river and the 200-ft. high on-line cross plains and a curved range over 2000 ft. high on steel towers.

Industrial Notes

Innovation supplied by the manufacturers.

In Bulletins 100, 101, and 102 of the STOW MANUFACTURING Co., Binghamton, N. Y., are described electric motors, portable electric tools, and the Stow flexible shaft with its many applications, respectively. To mine mechanics these publications are of interest.

In Bulletin No. 125 the JOSHUA HENBY IRON WORKS of San Francisco talks about Matteson mine-cars made by this firm. Important features of design are pointed out in red. The compound hinge allows the body of the car to be tipped to an angle of 10°, allowing for dumping on either side. Hyatt roller-bearings are fitted on the axles. Specifications are given for several types of cars.

The GENERAL ENGINEERING Co. of Salt Lake City has been employed by the Consolidated Coppermines Co. to re-construct the Gironx concentrator at Kimberly, Nevada, to treat 500 tons per day of Coppermines' ore. The treatment in the re-constructed plant will be by Callow flotation, followed by table concentration. Work started on September 8, and is in the direct charge of Walker J. Boudwin, one of the firm's engineers. About 60 men are now employed at the mill.

As a guide for mill-men, rather than for metallurgists, the GENERAL NAVAL STORES Co. of New York has issued a booklet which outlines the frothing and foaming properties of various kinds of oils, with suggestions for combining them to successfully treat a given ore. The publication really summarizes the company's observations on oils as applied to flotation. Details are given on the properties of G. N. S. flotation oils, and oil-mixtures. Interesting notes are presented on frothing agents, including pine-oils, coal-tar creosotes, coal-tar, and sludge-acid. Flotation oils may be divided into two general classes, namely, frothing agents and oiling or collecting agents.

Aerial tramways recently supplied by A. LESCHEN & SONS Rope Co. of St. Louis were as follows: Queen of the West Mines Co., Cornucopia, Oregon. A gravity two-bucket tram 3200 ft. long, the line having a fall in this distance of 1456 ft. This tramway will have a capacity of 6 tons of ore per hour, and replaces a single-line tram of another manufacture.—Cottonwood Coal Co., Lehigh, Montana. A two-bucket tram for the disposal of waste. This line has a length of 800 ft., and carries at the rate of 20 tons per hour. The tram has 1½-in. diam. special-steel track-ropes, and a ½-in. diam. traction-rope. The carriers are of 24-in. ft. capacity. The material is dumped by means of an aerial trip at any point along the line.

It has been said that the average person thinks of pipe merely as "a piece of steel with a hole in it." The NATIONAL TUB. Co. of Pittsburgh states that the widely ramifying use of tubular products is one of the romances of this country. Some of the uses of pipe are as follows: agricultural implements, automobiles, bedstead and hospital furniture, architectural iron work, grill work, building columns, refrigerating machinery, dry-kill apparatus, elevator cars, fence posts, ornamental fences, flag-poles, gymnasium apparatus, wheel-barrows, work benches, ornamental gates, elevator grain-spouts, invalid chairs, irrigation systems, safety ladders, loom cylinders, warship masts, lighting and high-tension poles, playground apparatus, electric-wiring conduits, railway-signal apparatus, spooling tube, lunch-counter stools, sprinkler systems, signal-towers, and at many places around mines and mills. There has been a decided change in material, as 50 years ago nearly all of the screw joint pipe was wrought iron. In 1905 the wrought iron and steel pipe amounted to 452,797 and 938,198 tons, respectively. In 1915 this was 262,198 and 2,037,266 tons, showing the great increase in steel for pipe. The company is erecting a new 600,000-ton per year plant at Gary, Indiana.

EDITORIAL

T. A. RICKARD, Editor

CARRANZA has abolished the vice-presidency of Mexico by decree, yet he remains First Chief of the Constitutionalist Party. The lack of a sense of humor is at the back of many calamities that befall mankind.

THE passing of resolutions demanding the development of our foreign trade is a sign of the times, but the learning of Spanish, Russian, and French would be a more effective means to that end. In linguistic preparedness we are a provincial people.

IT is reported that the management of the Granby Consolidated and other American mining companies operating in Canada are satisfied that no drastic action will be taken by the Dominion authorities in the matter of taxation. We published letters on the subject in our last issue.

SPEAKING of apex suits, the judge in the Phoenix Reef case in London, to which we referred recently, has become so wearied by the interminable wrangle that when the defendant's counsel said something about "the strike of the reefs," he interjected: "Strike! That is what I shall do if this case does not soon finish."

ONE of the notable episodes of the recent Institute meeting in Arizona was the luncheon given by the Calumet & Arizona Copper Company. This was served on tables arranged under the dust-chamber adjoining the blast-furnaces. The cleanliness of the extemporized luncheon-room was typical of the whole smelter-plant.

MINING engineers all over the world will be sorry to hear of the death of Bedford McNeill. To some of them he will be known only as the compiler of a useful code-book, but to many he was endeared as a kind and helpful friend, a good citizen, and an upright engineer. In London, where he lived, he will be missed as a sagacious co-operator in every kind of useful professional organization. He leaves an honorable name and a sweet memory.

APPEALS for subscriptions for the memorial to Joseph A. Holmes are being made by a committee that includes representatives of all the principal scientific and engineering societies. Twenty-two national societies are taking part in the organization, called the 'Joseph A. Holmes Safety Association,' of which Mr. Van H. Manning is president. One of the vice-presidents is Mr. Samuel Compers, representing the American Federation of Labor, and one of the members of the ex-

ecutive committee is Mr. Hennen Jennings, representing the American Institute of Mining Engineers. The intention is to award annually one or more medals, with honorariums, for the encouragement of those originating or developing safety devices or methods. The profession is invited to subscribe, sending their subscriptions to the honorary secretary, Mr. David T. Day, at Washington.

COPPER production during the first half of next year is anticipated to reach a total of 600,000 tons or as much as the refinery capacity in the United States. The recent sale of 200,000 long tons to Great Britain is equivalent to one-third of the output of metal to be made in this country during the first half of 1917, this deal calling for deliveries beginning in January next in monthly installments of 75 million pounds.

IF the news printed concerning conditions in Mexico were reliable, the public would be well informed, but it is not. For example, the *New York World* publishes a long story by a special correspondent and we might accept it as a fairly accurate picture, but the *San Francisco Examiner* re-prints it with a hasty endorsement and at once we doubt the truth of it. Mr. Hearst's paper is so prone to verbal inexactitudes that its statements have become uninteresting.

MR. WARBURG suggests that it is ridiculous for a country owning over two and a half billions of gold not to mobilize a larger free gold reserve than two or three hundred millions of dollars. Is it not equally ridiculous for a country having such natural gold resources in its mines and prospects not to stimulate the output of metal from them? The fact that 60% of the world's output of gold is produced under the British flag is peculiarly fortunate for Great Britain at this time. We produce only 20% of the world's output, but we ought to be producing a great deal more. National interest demands that mining of gold be encouraged in every way possible.

REFERRING to the unexplored mining area in the Far East Rand and the desire of the South African government to interest capital in the exploitation of this promising tract, we note that the Union Government is calling for tenders of lease on two areas covering 1812 and 651 claims, equivalent to 2718 and 976 acres, respectively. In the first lease \$4,000,000 is required for shaft-sinking and \$3,500,000 more for bringing the property to a productive stage; in the second lease a sum of \$1,500,000 is required for shaft-sinking and other

preliminary development, and a further sum of equal amount to bring the property to production. On this occasion an underwriting commission of 5% is allowed, but no vendor's or promoter's shares are to be created. It is probable that the Government has some intimation that tenders will be forthcoming, otherwise the advertisement would not have been made. Meanwhile the Labor party wants the Government to mine the undeveloped territory on national account, and the big financial groups in London or Johannesburg insist that the terms granted heretofore by the Government are not sufficiently attractive. Will the American syndicate bite? We believe not.

ON another page we give the first part of the opinion handed down by Judge Bradford in the suit of Minerals Separation v. Miami Copper Company, tried last year before the U. S. District Court of Delaware, at Wilmington. The decision is belated, for the trial ended in May 1915, so it is to be presumed that the Court has taken great pains to understand the technical issues raised in the course of the trial. The opinion is expressed in language that must command intellectual respect, the wording is clear and well chosen. We shall reproduce the essential portions of the text, omitting sundry paragraphs of an explanatory character aimed to help a reader not versed in the technology of concentration processes in general, or of flotation in particular. Owing to the exigencies of space we shall also omit a long description of the process appearing in patent No. 835,120, the references to the Fryer Hill publication, a lengthy excerpt from the Cattermole patent No. 777,273, another from the Kirby patent No. 809,959, and a summary of the British litigation over the Elmore bulk-oil process, which plays no part in the present flotation litigation. The first part of Judge Bradford's opinion covers the main issue; the second part, which deals with subordinate, but important, questions, will appear in our next issue, together with our own comment on the decision as a whole.

TEN years ago distillation was practically the sole method used in the extraction of zinc from its ores and concentrates. Development of hydro-metallurgic processes has advanced since then at so swift a pace as to offer a formidable challenge to the supremacy of the expensive furnace method. The Brunner Mond works in England are well known, where calcium chloride waste from alkali manufacture constitutes a source of active chlorine for dissolving the zinc as chloride from roasted ores, the metal being electrolytically deposited from this solution, yielding spelter more than 99.5% pure. Electrolytic zinc from sulphate solutions has been produced for many years in Germany and Russia, but the details of the industrial electrolysis have not been accessible, having been guarded in the medieval fashion as a trade secret. At Trail, British Columbia, the Consolidated Mining & Smelting Company of Canada is now producing zinc from complex ores by a method depending on these general reactions, without concealment

under a cloak of mystery. This will be the subject of an article in one of our forthcoming issues. Meanwhile we note a reference to the Isherwood process in the *Financial Times*, London. This process has much in common with the one employed by Mr. E. H. Hamilton at Trail, depending primarily upon the fact that zinc oxide is readily soluble in solutions of zinc sulphate under pressures ranging from three to fourteen atmospheres. Thus the roasted ore, treated with weak sulphuric acid, dissolves some zinc as sulphate, which in turn becomes the solvent for the remaining zinc oxide in the calcine, and is furthermore accommodating enough to discriminate against iron, which latter under the conditions of temperature and pressure maintained is scarcely touched. In the plant at Trail the reactions are obtained at normal pressure, and the solutions seldom contain in excess of 0.008% iron. An exceptionally pure spelter is the natural result.

STRIKES for higher wages in gold-mining districts are prompted mainly by sympathy with copper-mining regions, where the scale of wages is based, in large measure, on the price of copper. This, of course, works a hardship on the operators of gold mines; they are paying more for their supplies, from chemicals to machinery, than before the War, and are gaining no advantage from the big trade in munitions. Indeed, gold has depreciated in value as measured by the supplies, implements, or food that it will buy. On the other hand, the general cost of living has advanced 38% during the past twelve months, so that the miner's wages do not go as far as they did in the purchase of necessities. Evidently the employer and the employee on a gold mine are both suffering injury from the War and they should know enough concerning the basic facts to be considerate of one another. The strike at the Mother Lode mines of California is 'petering out,' we are informed, and we are aware of no reason why it should not. Some of the mining companies raised wages voluntarily last year and showed a fair spirit in the matter; it is a pity to make trouble through demands that are not just nor likely to be justified.

ANNOUNCEMENT is made that Mr. Fred. Hellmann has been appointed consulting mining engineer to the Guggenheim Brothers. The news is interesting, for Mr. Hellmann has many friends in the West that recognize the ability he has exhibited both in South Africa and Chile; but the announcement is also noteworthy by reason of the new style of the Guggenheim family firm: Guggenheim Brothers succeeding M. Guggenheim & Sons. When Meyer Guggenheim had created a big mining and smelting business he passed it to his sons, of whom there were seven, and now there are six, Isaac, Daniel, Murry, Solomon, Simon, and William. The youngest is not in the organization; in fact, he is conducting a bitter lawsuit over the division of profit in the Chuquibambata deal. Benjamin Guggenheim went down on the *Titanic*. Meyer Guggenheim, the founder

of the *haute finance* of American mining and metallurgy, landed at Philadelphia as a poor immigrant from Switzerland in 1847 and died in 1905. He was a man intensely acquisitive of information, shrewd, and hard-working. Beginning life as a dealer in lace, he lent money on a note that brought him eventually into the control of the A. Y. and Minnie mine at Leadville. Then he joined the enterprising 'Ed.' Holden in building the Philadelphia smelter at Pueblo and thus got a foot in the smelting business. By that time his lace business had enriched him so that he was able to transfer this smelting venture to his sons under the style of M. Guggenheim's Sons, not Meyer Guggenheim & Sons. How the smelter in Colorado became the first unit of an immense business we all know. Two of his grandsons are now in the organization, namely, Harry the son of Daniel, and Edmund the son of Murry, these younger men being in the employ of the Chile and Braden copper companies. The inheritance left by the founder has been developed and expanded by his sons until it has become synonymous with skillful and successful operations on the biggest scale known to the modern world.

Flotation in the South-West

In this issue we publish an article by Mr. David Cole on flotation practice in the Clifton-Morenci district and in preceding issues we have given our readers lengthy excerpts from the paper by Dr. Rudolf Gahl on the history of the flotation process at the Inspiration mine. These were the outstanding papers on the subject as discussed at the recent meeting of the American Institute of Mining Engineers, more especially at the session held at Globe. The metallurgical success achieved by the flotation process at Inspiration is romantic in its completeness. While a mill was being designed to treat the ore from a new and promising mine, the Minerals Separation company, then little known in Arizona, requested an opportunity to demonstrate the frothing process. On the request being granted, a 50-ton flotation unit was erected by the side of the existing test-mill. That was in 1913. Three years later the Inspiration is treating 16,500 tons daily by flotation and all of the machinery in the original mill-building, except three electric cranes, has been scrapped. Dr. Gahl gives the total cost of milling at 40 cents per ton, of which one-half represents crushing and grinding of the ore. The expense of flotation treatment alone—labor, oil supplies, and power—amounts to only 5.76 cents per ton. Royalty is not included in any of these figures, it ranges from 7 to 12 cents per ton, according to the tonnage. The recovery on the sulphide copper minerals is about 92%, but the average is reduced to 74% by the presence of some oxidized ore, on which the recovery is only 20%. In short, the metallurgical treatment is not yet perfected. It is noteworthy that a better recovery is made on pulp of minus 200-mesh than on the coarser product; this is nothing new in gold-milling, but it serves to emphasize the fact that the slining of copper ore is not a

detriment, and thus marks the great divergence of practice between flotation and the old wet-concentration methods. As to machines, the Inspiration staff tested a number of them, finally evolving one of their own design that did better work than any other. It was modeled on its predecessors, the Callow, Flinn-Towne, Cole-Bergman, and Hebbard apparatus. In its final form it approaches the ideal of a launder with a porous bottom. It is made of steel; all pipe-connections are from above and therefore readily visible; an air-tight joint is established where the pipe passes through the porous medium into the air-chamber. The consumption of air is 11.8 cubic feet per minute per square foot of porous surface. Various substitutes for canvas were tried; for example, sheets of rubber and rubberized canvas, and the results were encouraging, but not conclusive. As regards flotation agents, the *hocus-pocus* of special mixtures of oils was early disproved by experiment, to the discomfiture of the 'experts.' A man that claims to be an 'expert' in a process as yet so little understood as flotation deserves an iron cross. After using cresylic acid 98% pure and grumbling at even a 2% shortcoming, it was suggested by the frankly non-expert metallurgist that cresylic acid might not represent the particular fraction from coal-distillation that was most useful in a flotation-cell. So tar was distilled from a sample of ordinary soft coal, from New Mexico, and this home-made coal-tar proved an excellent flotative agent. Cresylic acid produces a froth with less carrying power, apart from its expense. Even coal-tar creosote was rejected finally in favor of crude coal-tar, which is the cheapest and best flotation agent, for Inspiration ore, if added to the ore while in the grinding machines, so as to ensure thorough emulsification with the pulp. Incidentally, we may mention that the Inspiration ore is a schist containing 1.17% copper in the form of chalcocite, and a little chalcopyrite, with 0.39% more copper as a carbonate or silicate. In August the mill-feed averaged 1.56% copper and the concentrate 30.22%, while the tailing contained 0.417%, of which 0.325 was oxidized mineral. The weight of flotation agent (coal-tar) averaged 1.31 pounds per ton of ore milled.

Coming to Mr. Cole's paper, which we reproduce in full, it will be noted that he furnishes details of the C-B machine devised by himself and Mr. Julius Bergman. It was designed to overcome a defect noted in the operation of the Flinn-Towne machine, the distinctive feature of which is a round disc of carborundum, serving as a porous diaphragm at the bottom of a cylindrical vessel. The sand had a tendency to lie upon the carborundum and impede the passage of the air, so Messrs. Cole and Bergman substituted a set of perforated tubes covered with a porous fabric, such as canvas or flannel. This invention followed upon the successful application of a tube-grate air-filter in the drag-belt trough, as Mr. Cole explains in detail. Thank heaven! the devising of new machines for flotation is not under the embargo of the Patent-Office. Most of them are modifications of older devices and none of them seems to be essential to

the successful operation of the process. Froth can be made in many ways. At Chino, the Janney machine is paramount. There the notion of strenuous stirring is in the ascendant. 'Emulsification' is the pass-word. Nevertheless, it is to be noted that pneumatic treatment has been introduced into the spitzkasten part of the Janney machine. This is said to save power. But the latest feature of the Chino Copper Company's operations at Hurley is the new process for treating oxidized ore. An experimental plant of two tons capacity is trying a combination of leaching and flotation. The ore, which contains both oxide and sulphide copper minerals, is ground to 80-mesh in a tube-mill and then fed to a table that removes the coarser grains of sulphide. The reject from this table goes to a tank in which it is leached with a weak solution (3 pounds of acid per pound of oxidized copper) of sulphuric acid. It is stated that the 'digestion' of the copper oxide is rapid. The 'digested' pulp is fed then into a cylinder filled with iron-turnings and rotated, so as to prevent the settlement of sand and hasten the precipitation of the copper on the iron, which is thus kept bright and clean. In passing through this cylinder the copper is precipitated completely and the acid is neutralized at an expense of two pounds of iron per pound of oxidized copper. The neutralized copper and the sulphide are then alike in a fine state of division and readily amenable to recovery in a flotation-cell. Credit for this new departure is due, we understand, to Dr. H. W. Morse. Evidently the South-West, which is now the greatest copper-mining region in the world, is destined to contribute its share to the new metallurgy. More records of progress will be forthcoming; so we venture to suggest to writers on the subject that they should start their accounts of milling methods or metallurgical experiments with a plain description of the ore in question. To those living in Arizona or New Mexico the character of the ore at Miami or Chino is known, but to those living in distant localities and reading the papers of our technical friends in the South-West it is a great boon to be told exactly what is the chemical composition and petrographic character of the ore, for purposes of comparison.

Those Copper Quotations

Reverting to this interesting subject, we note that Mr. Walter Douglas, in a letter widely published, mentioned that rumors had reached him that "the large copper-producing interests have financial control of the *Engineering and Mining Journal* and that it is naturally to their interest that the copper quotations therein should be under, rather than over, the market, on account of the bearing which it has on the sliding wage-scale. Did this condition obtain, which it does not, the copper producer or seller would be injuring himself through the publication of such a quotation, as whereas a portion of the high price of copper goes to labor, a greater proportion goes to the producer, and it is obvious that the producer will obtain as much as he possibly can for his output and not give the purchaser and consumer

the impression that the price of copper is lower than that which he is asking for it." As to the sinister suggestion mentioned at the beginning of Mr. Douglas's statement, we believe it to be as baseless as he believes it to be. The *Journal* used to be independent of any smelting or mining company, and we have not the least reason to believe that it has divagated from that attitude of detachment. However, we do believe in the unconscious influence of propinquity and consider it not unfair to infer that a paper published at New York will reflect the ideas current in an environment of metal-sellers. The argument offered by Mr. Douglas is one that we cannot follow. Do the producers sell their copper on the *Journal* figures? Of course not, they bargain with the buyers and brokers. The smelting companies buy ore from the smaller producers on the basis of the *Journal* figures, but the smelters sell on the best figure they can get through their own selling agencies. How a low quotation reducing the wages paid to the miners would injure the copper-producing company, in the manner suggested by Mr. Douglas, we do not understand. Apparently Phelps, Dodge & Co. does not sell on the *Journal* figures if the average price received by that company in 1915 was 16.05 cents as against a *Journal* average of 17.27 cents. On the contrary, we see no reason why the smelting companies should not have settled for wages to the miners and bought ore from the mine-owners on the *Journal's* July average of 23.86 cents while selling its own copper at New York on the average reported by us as having been 25.66 cents. We are at a loss to understand why a labor-union or a mining company should agree to base its scale of wages or its settlements for ore upon the guess of a single trade paper, when the suggestion of this arbitrament comes from the buyer of the labor and of the ore.

It is about time to discover some better method of adjustment between buyer and seller. Why not base the wage-scale and the ore-settlement alike on the price that the mining or smelting company gets for its copper? Why depend on the guess of any trade paper when the essential fact can be ascertained by reference to an authentic record, namely, the books of the copper producer or the smelter, as the case may be? What does it matter to the manager of the Little Bullion mine what other people are getting for their copper? He settles with the smelter on the basis of the price that the smelter is supposed to get for the copper that it buys from him. What does it matter to the copper miner at Bisbee what the Anaconda company gets for its copper? He is only concerned with the price obtained by the particular company that employs him. It may be objected that an interval must elapse between the purchase of custom ore or of miner's labor and the marketing of the copper sold by the one or mined by the other, but that is easily adjusted: pay a nominal price on settlement, and adjust the balance at the end of a specific period. The price at which copper is sold by a given individual or company can be ascertained definitely; the average price at which a variable number of producers sell varying quantities of copper cannot be determined by anybody.

The Wilmington Decision on Flotation—I

Text of Opinion by Judge Bradford in the U. S. District Court

The bill in this suit was brought by the Minerals Separation, Limited, a corporation of Great Britain, against the Miami Copper Company, a corporation of Delaware, charging infringement of three United States process patents relating to ore concentration, owned by the plaintiff, namely, No. 835,120, of November 6, 1906, to H. L. Sulman, H. F. Kirkpatrick-Picard, and J. Ballot, No. 962,678, of June 28, 1910, to H. L. Sulman, H. H. Greenway, and A. H. Higgins, and No. 1,099,699, of June 9, 1914, to H. H. Greenway, assignor to the plaintiff.

Under the processes shown in the three patents a signal advance has been made in the art of ore concentration in point of simplicity, economy and efficiency, and in their practice large commercial success has been realized. * * * Without pausing at this point to consider other processes of ore concentration disclosed in the prior art, hereinafter discussed, an important and, indeed, vital difference between water or gravity concentration under such processes as those above referred to, on the one hand, and concentration under the processes of the patents in suit, is that while in the former the metallic particles after being separated from the gangue in the ore pulp sank to the bottom, in the latter the metallic particles coated with an extremely thin film of oil, become attached to air-bubbles in the ore pulp, and the bubbles with the attached metallic particles rise to the surface, forming a mineral froth of such coherency and permanency as to afford full opportunity for its removal from the surface for further treatment of the metallic particles. The ore pulp in the process of each and every of the three patents in suit consists of a mixture of water and crushed or pulverized mineral ore, together with one or more other ingredients. In each the agitation of the pulp coupled with the introduction of air into it develops and distributes throughout the mixture small bubbles of air which attach themselves to the metallic particles, to the exclusion of gangue, and rise with them and form a metallic air froth on the surface, readily removable therefrom, the gangue particles sinking to the bottom and being disposed of as refuse.

* * * * *

The charge of infringement of patent No. 835,120 is restricted to claims 1, 9, and 12, as follows:

"1. The herein-described process of concentrating ores which consists in mixing the powdered ore with water, adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter, (amounting to a fraction of one per cent on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth, and separating the froth from the remainder by flotation."

"9. The process of concentrating powdered ores which consists in separating the mineral from the gangue by coating the mineral with oil in water containing a small quantity of oil, agitating the mixture to form a froth, and separating the froth."

"12. The process of concentrating powdered ore which consists in separating the minerals from gangue by coating the minerals with oil in water containing a fraction of one per cent of oil on the ore, agitating the mixture to cause the oil-coated mineral to form a froth, and separating the froth from the remainder of the mixture."

The first patent in suit is for what is known as an air flotation process, in which, owing to the use of a frothing agent in conjunction with such agitation of the ore pulp as will distribute the metallic particles of the ore throughout the mixture and produce bubbles of air and bring them in contact in the mixture with the metallic particles so distributed, the bubbles will become attached to such metallic particles, carrying them separate from the particles of gangue up through the surface of the mixture where they can readily be collected by skimming, overflow, or the use of other well known devices. In this process the frothing agent consists of an oil or other immiscible substance or material of an oily nature, and the bubbles and metallic particles become attached to each other through affinity between the bubbles and the metallic particles enhanced by the coating of the latter with an extremely thin film of oil. The old water processes of ore concentration were in some features gravely objectionable. Under those processes it was desirable to avoid very fine grinding of the ore as being calculated to cause the fine particles containing metal constituting the slimes to escape with gangue particles and be lost, such fine metallic particles, as before stated, not sinking so readily and quickly as those which were larger. In those processes there were two things to be avoided; first, the crushing or grinding of the ore to such a degree of fineness as to lead to the loss of metallic particles through their escape with gangue particles, and secondly, too coarse a crushing or grinding whereby particles of ore containing both metal and gangue might, with the gangue preponderating, too readily be carried to the surface and lost with the other gangue particles. The defendant admits in its brief that the air bubbles collect the metallic particles, and the oil or other modifying agent in the mixture gives permanency to the mineral froth; that the attraction of the air bubbles for the metallic sulphide particles leads to the separation of those particles from the gangue; that in the absence of oil or other modifying agent in the pulp, facilitating the formation of air or

other gas bubbles, no process of ore concentration employing such bubbles is possible; that air flotation may be brought about (1) by introduction of air at the bottom of the mixture or sub-aeration; (2) by beating air into the mixture or supra-aeration; (3) by generation of gas or liberation of air in the mixture. But there is an accentuated difference of opinion between the parties on the point of preferential affinity of oil for metallic particles as compared with gangue. The defendant in its brief states that "in ore flotation processes the oil or other modifying agent does not have any more attraction for the metallic particles than for the gangue." This position, however, is in conflict with evidence on the part of the defendant, with the evidence on the part of the plaintiff, with the documents of the art, and with the result of the physical demonstrations made by both parties in open court.

One of the principal questions in the case is whether patentable invention was involved in the discovery that the minute proportion of 0.1% of oil to the ore was sufficient for commercially successful operations in ore concentration. On this question I had some doubt during the presentation of the case. But that doubt has since been removed. Sulman, Picard, and Ballot had for more than two years prior to March, 1905, been interested in conducting ore concentration under what was known as the 'Cattermole process,' and had been seeking to improve the same in such manner as to render it more efficient and less expensive. There were a number of patents relating to this process, using the term in a general sense, among which were No. 763,259 of June 21, 1904, No. 763,260 of June 21, 1904, and No. 777,273 of December 13, 1904, all to A. E. Cattermole. In the process of each of these patents metalliferous granules are formed and separated from the gangue and fall to the bottom, while the gangue is carried up and away.

Shortly before March, 1905, Sulman, Picard, and Ballot instructed A. Howard Higgins, one of the plaintiff's experts, to investigate by experiments, certain points in their bearing upon the Cattermole process of granulation. They were as follows:

- "(1) Influence of acidity on granulation.
- "(2) Influence of temperature on granulation.
- "(3) Influence of speed of Gabbett agitation on granulation.
- "(4) Influence of ratio of ore to liquor on granulation.
- "(5) Influence of metallic salts on granulation.
- "(6) Influence of the size of particles and of the influence of slimes on granulation.
- "(7) Influence of the amount of oil on granulation."

And the above points were to be determined on "(a) oleic acid, (b) residuum oils." In consequence of his investigations Higgins made a report March 16, 1905, on granulation as affected by the percentage of oil used, in which he said:

"The effect of diminishing the percentage of oleic acid is to alter the type of oiling; the higher percentages pro-

ducing granules, and the lower ones froth. 6% of the oleic acid on the mineral is sufficient to form good granules without much froth. This froth consists of insufficiently oiled mineral mixed with large quantities of air. As this percentage of oleic acid is decreased, the time for clean up of the sands is increased and more froth is formed. 0.62% oleic acid on the mineral is insufficient to form any granules and nearly the whole of the mineral comes to the surface, on stopping the cone, as froth. 0.2% acts in the same manner, leaving the coarse sands with rather more mineral in them. (This is 0.1% on Broken Hill ore.) In all cases the oil has been measured in cubic centimetres and the percentage calculated as though they weighed grams, but as the specific gravity of the oleic acid is less than unity this is not the case, and all percentages will be lower than those actually given."

There was, I think, patentable invention in the discovery thus made in March, 1905. Prior to that time there had been no suggestion in the art that the proportion of 0.1% of oil to ore or of any other fraction of 1% of oil to ore would or might result in successful concentration. Further, the result reached was an utter surprise. Experiments were conducted with reference to the Cattermole process, and all of the Cattermole patents required the formation and sinking of granules containing the metallic particles, and not their flotation. The teaching of that process was that the metallic particles should go to the bottom and that of the process of the first patent in suit that they should go to the top. But while the ascertainment that such a minute proportion of oil would effect a successful concentration of ore through a flotation process was a discovery, it was nevertheless of such a character, viewed with respect to the circumstances under which it was made, as to involve invention and confer patentability. The statutes provide for patenting new and useful inventions and discoveries, but a bare discovery unaccompanied by the exercise of any invention in reaching it or utilizing or reducing it to practice would not justify or support a monopoly in the discovery. In the present case, however, the facts disclose not a bare discovery, but a discovery coupled with invention in usefully applying it. In such cases patents properly may be granted. The defendant lays much stress upon the proposition that the reduction of the amount of oil in the process for the concentration of ore did not and could not involve patentable invention, but only an ascertainment of the proper degree in which oil should be used, which was readily discoverable by any one competent to conduct or superintend a process of ore concentration; and further, that motives of economy would naturally have suggested a reduction in the quantity of oil to the extent of its excess over what was necessary for the accomplishment of the purposes of the process. But if such a reduction was obvious, why is it that it was never made prior to the discovery in question? The fact that economy required the use of the least quantity of oil sufficient for the conduct of the process affords cogent evidence that the feasibility of effecting a reduction

was not obvious, but properly the subject of patentable invention. No one today understands how the use of only 0.1% of oil operates to secure the mineral froth of the first patent in suit. This is testified to by experts and is admitted on both sides. If the principle of operation of the discovery is insolvable to the human mind today it could not have been predicted or anticipated by the human mind in March, 1905. The fact that the underlying principle of the process was not understood by no means negatives patentability. * * * * *

This case is unlike those in which the discovery of the use of an element in a process in the degree insuring the best results is a matter within the competency of those skilled in the art, but, on the contrary, is one where clearly there was patentable invention or discovery in ascertaining the degree. The experiments made with respect to the Cattermole process were initiated with a view to its improvement and the securing of granulation of a higher efficiency. The prosecution of the experiments relating to a sinking and not a flotation process would naturally tend to divert the mind from the contemplation of any process of the latter character. Pertinent to this point is the following testimony of Mr. Higgins:

"I do not remember anything being said about the quantity of oil, except the quantity used was always adjusted to give granulation.

"44Q. In adjusting the oil to give the best granulation, I presume you experimented with different quantities of oil?

"A. Yes, there may have been different quantities, but whenever the granulation became imperfect by reason of the drop in the quantity of oil, the oil was naturally increased."

I perceive no escape from the conclusion that the discovery was patentable. To decrease the amount of oil used in an old process, so long as the characteristic mode of operation and result of such process are preserved, even though in less degree, does not as a general rule involve invention. But when the old mode of operation and its result through a decrease in the amount of oil disappear and a new and different result is disclosed the change ceases to be one of mere degree, and may support a patent monopoly in favor of one whose inventive genius or research has discovered the process. The patentability of the process of the first patent in suit resides in the use of only the minute quantity of oil contemplated by the patent. The reduction of the oil to this quantity effected a change, not merely in degree, but in the "type of oiling," leading to results which cannot be accounted for on the assumption that a mere change in degree as distinguished from patentable discovery was involved.

The defendant contends that a substantial increase in the amount of oil used will not affect the nature or efficiency of the process of separation, but will only add to the cost by carrying it on with an unnecessary amount of oil. But this position is in conflict with the decided weight of the evidence and with the showing of the experiments conducted by Higgins at and immediately

prior to the time of the discovery. It is satisfactorily proven that the process of the first patent in suit, depending upon the selective affinity of the air-bubbles in the mixture for oil-coated metallic particles, that affinity is strongest when the film of oil surrounding the metallic particles is so thin as to be imperceptible to the senses, and that with any substantial increase in the quantity of oil on the metallic particles the character of the process is changed and its efficiency diminished for some reason as yet unrevealed.

A great advance in the art of ore concentration has resulted from the process of the first patent in suit in the efficient recovery of slimes. With the use of that process ore may be so finely ground as to insure the thorough separation of the metallic particles and gangue, and great savings effected. The profit so saved in a single year from the output of the principal porphyry copper mines, including the defendant's, has been estimated by one of the expert witnesses as more than \$17,000,000. In *Moore Filter Co. v. Tonopah-Belmont Development Co.*, 201 Fed. 532, 540, the circuit court of appeals for the third circuit, in dealing with an ore concentration case, said:

"When, therefore, Moore disclosed a process by which such recovery was made enormously profitable, and by which he turned a dump heap, which, under all known processes, machines, and laboratory methods, was worthless, into profitable ore, we are constrained to give little weight to the suggestion that his process was either anticipated, a mere advance incident to the art, or involved no invention."

The defendant sets up as part of the prior art to negative invention United States patent No. 689,070 of December 17, 1901, to A. S. Elmore. This patent was for an "Improvement in separating mineral substances by the selective action of oil," and contains but one claim as follows:

"The process for separating metallic and rocky constituents of ore which consists in mixing pulverized ore with water and mixing the ore and water with oil in the presence of an acid, allowing the mixture to rest whereby the oil having the metallic substances entrapped in it floats at the top of the mixture, and separating the metallic constituents from the oil, substantially as described."

In the description it is stated:

"The selective action of oil has been utilized for separating metallic substances from earthy or rocky constituents of ores. This has generally been done by pulverizing the ore and suspending it in a considerable quantity of water, so as to make a freely-flowing pulp, then mingling with it oil, preferably heavy oil, such as is obtained from petroleum after some of the lighter oils have been distilled from it. When the mixture rests, the oil, with most of the metallic substances entrapped in it, floats at the top and is separated from the rocky or earthy matters, which are run off with the water as tailings. The oil is afterward separated from the metallic substances, usually by centrifugal action."

The patent nowhere states the amount of oil which is

to be used or the ratio between the weight of the oil and the weight of the ore or its metallic content. It, however, clearly appears from the evidence that the process was what has been termed a "bulk oil process," employing from one to two and a half or three tons of oil to each ton of the pulverized ore to be treated. By reason of the large amount of oil used and the loss of a considerable proportion of it in operation the process was expensive and unsatisfactory. There was but a small recovery from the slimes, probably for the reason that the extremely minute metallic particles contained in them did not yield to centrifugal action employed in the separation as readily as the larger particles.

* * * * *

The defendant also relies upon the patent No. 348,157 of August 24, 1886, to Carrie J. Everson, for an "Improvement in processes for concentrating ores," as part of the prior art. The patent specifies two methods of conducting the process. It is admitted that the first method requires oil amounting to 5% on the weight of the ore. With respect to the second method it is stated in the patent description:

"I have found three fluid drams of oil abundant for properly moistening two ounces of heavy ore, or in the ratio of about a barrel of oil to the ton of ore, the amount being, of course, variable with the relative bulkiness of the ore."

Dr. Liebmann testifies that the oil used in the process was 16.5% of the weight of the ore, and Dr. Sadtler says that the amount of oil so used was from 16% to 17% of the weight of the ore. The Everson process has never been used commercially and Dr. Liebmann states that it could not be so used; that "it is not a process for large scale operations"; but that there was a possibility of its application to gold and silver in small quantities. Dr. Sadtler expresses no opinion upon the applicability of the Everson process to the concentration of ore on a commercial scale, and states, in substance, that he had never practiced the Everson process in either of the methods disclosed in the description of the patent. The defendant argues that in the Everson process the concentrate "could not possibly float by the bulk oil flotation principle, for the simple reason that the amount of oil was insufficient for that purpose"; that with the use of only 17% of oil no bulk oil flotation is possible; and that the process "could not have resulted in surface tension flotation, skin flotation, or film flotation, so-called, for the simple reason that the conditions for that form of flotation were absolutely wanting." But this contention fails, I think, to negative patentable invention in the process of the first patent in suit. I am not satisfied by any experiment or demonstration made in the case that the process described in the Everson patent would produce the economical and efficient concentration secured by the process of the first patent in suit. Certainly, were there nothing else, a reduction in the quantity of oil from 17% or even 5% to a fraction of 1% on the weight of the ore, under circumstances similar to those attending the discovery of the sufficiency of that

minute proportion for successful metallurgical operations would be sufficient to confer patentability.

* * * * *

Much stress is laid by the defendant upon an article in the *California Journal of Technology* of November, 1903. This article was prepared by three young men, students in the class of 1903 in the mining department of the University of California, and is entitled 'Experiments on the Elmore process of ore concentration.' This article is suggestive, but cannot, I think, be justly treated as negating the exercise of invention with respect to the process of the first patent in suit. The experiments were laboratory tests and did not disclose or suggest the idea that such a minute quantity of oil as one-tenth of one per cent, or any fraction of one per cent, on the weight of the ore could be efficiently and successfully employed in ore concentration. There were a number of tests with respect to the concentration of molybdenite ore with percentages of oil to ore running from 2.1% to more than 100%, with the result that the highest extraction of molybdenite sulphide was obtained by the use of 8.9% of oil; the extraction in that case being 75% as against an extraction of 43.5% obtained by the use of 2.1% of oil. The teaching of these tests was that 2.1% of oil, was less efficient than the use of 8.9%, and the article as a whole, far from suggesting the possibility of the use of only a fraction of one per cent of oil points to an opposite conclusion.

The defendant contends there is nothing new in the employment of only a fraction of one per cent of oil relative to the weight of the ore in the process of the first patent in suit, for the reason that, as alleged, an equally small proportion of oil was used in the process of the Cattermole Patent No. 777,273, mentioned in the first patent in suit. The Cattermole patent mentions from four to six per cent in weight of oil to the weight of the metalliferous mineral present in the ore, and consequently, under the Cattermole process the amount of oil to be used depends upon the weight of the metalliferous mineral, and not upon the weight of the entire ore, and there is evidence to the effect that the larger part of the copper ores mined and concentrated in this country contain about two per cent of copper. Hence the argument is made by the defendant that the weight of oil employed in the Cattermole process is only from 0.8 to 0.12% of the weight of the copper contained in the ore, and that any proportion of oil less than one per cent of the weight of the ore comes within the quantity mentioned in the first patent in suit, namely, "a fraction of one per cent on the ore." This contention ignores the following statement in the description of the Cattermole patent now considered:

"In certain cases, as where but little mineral is present in the ore, to increase the nucleating or granulating factor pulverized mineral matter obtained in a previous operation or other matter having an affinity for oil from a different source may be introduced into the ore, or a portion of already granulated and separated mineral

matter may be returned to maintain the necessary amount of mineral in the ore under treatment."

It is evident that the weight of "pulverized mineral matter" introduced to "maintain the necessary amount of mineral in the ore under treatment" is, for the purpose of determining the necessary amount of oil, to be added to "the weight of metalliferous mineral matter present in the ore." Such must be the meaning of the patent or it is insensible. And this accords with the requirement in the seventh claim of "adding particles of material having an affinity for oil to assist in the formation of granules of oil-coated particles." The defendant has made no demonstration, as might have been done, of the amount of oil required by the Cattermole process in its application to lean copper ores, but indulges in speculation and conjecture on that point. The defendant contends that in the Cattermole process of the above patent there were necessarily two degrees of agitation of the mixture; the first being violent and the second gentle. On the assumption that two degrees of agitation were required in the Cattermole process; first, violent agitation of the mixture in order to bring the oil into intimate contact with the mineral particles; and, secondly, the subjection of the mixture to a slower or rolling form of agitation to cause the agglomeration of the oiled metalliferous particles and the formation of granules, it by no means follows that with the omission of the second step the mineral froth of the process of the first patent in suit would have been formed, had there been in the mixture oil in excess of the proportions contemplated by that patent. And if it be further assumed that the mixture containing oil and other elements in Cattermole proportions can first be violently agitated so as to produce a froth and then slowly agitated so as to produce granules, and again violently agitated so as to destroy the granules and restore the froth, and so on by alternation, and that, the mixture remaining the same, the production of froth on the one hand, or granules on the other, is simply a matter of manipulation, it is not to be inferred that the froth so formed with Cattermole proportions of oil would be the froth of the first patent in suit. Dr. Liebmann, for the purpose of distinguishing between the Cattermole process and that of the first patent in suit, during the trial conducted two experiments, identical in their nature, save that in one a larger amount of oil was used than in the other. In the former case granules were formed which sank; and in the latter a mineral froth was formed, the agitation and other factors being the same. 3.6% of oil and 0.1% of oil were respectively used in the two experiments. Both were performed in the same apparatus with similar materials and manipulation. These experiments served to show that the variation in the amount of oil used, other things being equal, may result in the formation of the mineral froth of the first patent in suit, or in the formation and sinking of the granules of the Cattermole process. In this connection it is to be observed that the Cattermole patent in its descriptive portion states:

"With certain ores it may be preferable to use in some stages of the process a rolling form of agitation,

as in cylinders or barrels, to obtain good granulation of the mineral."

The description of the patent nowhere specifies that its process is necessarily dependent upon two degrees of agitation, one violent and the other slow or rolling, and in none of the seven claims of the patent, with the exception of the fifth, in such a requirement mentioned or suggested. In that claim only is there a provision for "further agitating the mass to increase the size of the granules," and even in that claim there is no suggestion of a difference in degree between such further agitation and the agitation which has preceded it. For the foregoing reasons I think that the contention of the defendant that the quantity or proportion of oil used in the Cattermole process was not materially in excess of that used in the process of the first patent in suit, and that, not a difference in the quantity of oil, but a resort to two degrees of agitation was essential to the formation of Cattermole granules, cannot be sustained.

The defendant also relies upon two patents granted to Alcide Froment; one of them being British patent to Henry Harris Lake, communicated by Alcide Froment, No. 12,778 of 1902, and the other an Italian patent to Froment, No. 63,723, the specification of which is dated May 20, 1902. The Froment Italian patent was in the French language, and there is an English translation in evidence. The process covered by this patent was entitled "A process for enriching sulphide and copper ores, lead ore and blende by gases combined with fatty bodies." The inventor stated as phenomena which had been studied by him and served as the basis of the patented process the following:

"1. When the natural sulphides reduced to fine powder are moistened by a fatty substance, they have a tendency to unite in spherules and to float upon the surface of water.

"2. This tendency is simply retarded by the specific weight, and opposed by the gangue which imprisons the moistened sulphides in its pulverulent mass.

"3. If a gas of any kind is generated in this mass, the bubbles of this gas become covered with an envelope of sulphide and thus rise readily to the surface of the liquid where they form a kind of metallic magma.

"4. The formation of these metallic spherules is singularly active, if the gas is in a nascent state."

(To be Continued)

OPERATING REVENUE of United States steam railways during the year ended June 30, 1916, totaled \$3,396,808,234, an increase of \$508,359,921. Operation cost \$2,220,004,233. These roads cover approximately 230,000 miles, or 90% of the steam mileage in the country.

TIN-PLATE EXPORTS of the United States exceed any previous records, and in the first half of 1916 totaled 122,839 tons, or 20,473 tons per month. In the year ended June 30, 1915, the rate was only 6667 tons, and in the previous year 3939 tons per month.

FERRO-MANGANESE is quoted at \$170 per ton.

Flotation in the Clifton-Morenci District, Arizona

By David Cols

*At the time flotation appeared upon the metallurgical horizon of Arizona, the writer, under the direction of Dr. L. D. Ricketts, was engaged in re-modeling and enlarging the No. 6 concentration plant of the Arizona Copper Co. at Morenci, and the work had been in progress nearly a year before the Inspiration experiments with flotation disclosed the revolution in concentration that was impending.

The simplified flow-sheet for the Morenci plant had been based upon the removal of the freed metal in a minimum number of stages by treatment upon tables equipped with Butchart riffles, the latter being adapted to accomplish both classification of feed and removal of the metal at one operation.

The scheme of treatment for the slime was based upon the fact that after copper sulphides, such as chalcocite and chalcopyrite, are reduced to a certain state of comminution they are definitely beyond the reach of separation upon any of the concentrating devices then known.

By using drag-belt classifiers (which served as conveyors as well as separators), the overflow would be of the usual 'slime' class. Experiment had shown that when these drag-belt overflows were properly diluted (that is, to about 5 to 7% solid in the feed under treatment) the fine sand, and especially the fine but still granular sulphide particles, would, if given a short distance to fall, settle quickly in prime condition to yield an excellent recovery on vanners; further, the fine non-separable final overflow might be discharged direct to tailing, thus conserving space.

For reasons that are obvious, this kind of feed preparation for the slime could not be accomplished successfully in any form of pointed box or spitzkasten, therefore a further elaboration of the drag-belt idea was worked out as the best method for accomplishing the separation. This machine was known as a colloid separator and is shown in Fig. 1 and 2. It works on the premise that nearly all of what may be called ponderable material in the thinned pulp, falling but two inches, will lodge upon the belts and be removed, while the flocculent slime will remain in suspension and go away with the overflow. In this way a feed is prepared for the vanners containing a maximum amount of the very fine but granular sulphides and a minimum of colloidal material; at the same time the drag-belt overflow contains a minimum of sulphide particles and a maximum of flocculent slime. This final overflow was found to be

approximately two-thirds of the total tonnage handled by the belts, so that treatment upon vanners was devoid of beneficial results. The copper escaping in this overflow was in the form of fine chalcocite, bornite with a little pyrite and chalcopyrite, together with oxidized, and water-soluble, copper salts. Taken together, these gave the overflow a copper tenor of from 1 to 1.3%, thereby accounting for the larger part of the tailing loss. However, this overflow, with its ultra-fine and otherwise handicapped copper-bearing material, was practically beyond the reach of any concentrating machine at that time known, and could therefore go to tailing. A Dorr thickener 130 ft. diam., the first one of such large size, was devised to recover the water from this overflow before it was allowed to go to waste. See cover of this issue.

By this plan, the treatable portion of the slime could be handled by the complement of vanners already installed in the mill. This arrangement, in conjunction with the saving in floor-space, resulting from the introduction of the Butchart riffle, made it easily possible to double the capacity of the plant under practically the original roof. While it did not promise to recover a larger percentage than usual of the truly slined copper, it did promise to give the best possible results in one-half the space.

By the time this flow-sheet had been put into practical operation, the Inspiration experiments were attracting wide-spread attention and flotation was beginning to be taken seriously as a process for the concentration of copper ores. It was, however, still regarded as an auxiliary process and was thought to be inapplicable to ores carrying an excess of tale or clay, like the Clifton-Morenci ores. Some experiments with the Elmore process on these ores in former years had been unsuccessful and laboratory work that we did later on a small scale seemed to corroborate this view. Space was reserved, however, in the mill-building for the installation of flotation equipment in case further development should prove it desirable.

Meanwhile, the Inspiration company had built the 600-ton pilot mill, in which the new process was rapidly graduating from an auxiliary into the main method of separation, in the manner so fully described by Dr. Rudolf Cahl.¹ Starting with semi-mysterious compounds, the Inspiration staff soon found that simple flotation reagents were equally efficacious. Through the

*Abstract of paper read before the Arizona meeting of the American Institute of Mining Engineers, in September 1916.

FIG. 1. DRAG-BELT SEPARATORS IN MILL OF ARIZONA COPPER CO.

kindness of Mr. Charles E. Mills, the manager, I secured a drum of cresylic acid and some pine-oil with which to try a few experiments at Morenci.

The tailing from the No. 6 concentrator was at that time discharged into Morenci canyon and cascaded for about one mile before being taken into a flume to be carried to the impounding dams. The creek-bed was rough and steep, inducing great agitation of the pulp and resulting in the production of large amounts of white froth, which floated down the stream. This froth ear-

ried no concentrations of copper minerals, but I thought it might be possible to change its character and produce a mineral froth by the use of flotation reagents introduced where the tailing left the mill, and thus possibly secure from the natural situation some benefit at little cost.

A small can of the cresylic acid was arranged to drip into the tailing-launders at a point where the tailing made its first plunge into the creek-bed. The results were instantaneous. Black froth began to collect in

FIG. 2. ANOTHER VIEW OF DRAG-BELT SEPARATORS.

eddies and float down-stream for a few yards to a second plunge where we were greatly surprised to find that it became white again on account of the instant dropping of the metallic load. Feeding the reagent into the stream immediately above the second plunge would not cause a mineral-froth to rise as in the first plunge, and the failure was finally debited to a town sewer which was discharging under the surface into the creek between the two pools; the sewage effectively killed the metal-carrying capacity of the froth.

Cresylic acid was then added to the feed of a re-grinding Hardinge mill, which was discharging into a long drag-belt classifier. The results were again most encour-

bends. The pipes were drilled full of small holes and were wrapped with cotton blanket tied with spirally wound wire. This tube-grate air-filter was put into the drag-belt trough as deeply as possible, without touching the belt. Coarse sand could pass through between the grates and be removed by the belt underneath. The pipes were supplied with compressed air for the purpose of creating additional froth, and it was found that the product, without further treatment, assayed 40% copper, 1.14% of which was oxidized, and that it carried but 20.4% insoluble.

Plans for a small frothing-machine of the mechanical-agitation type were made immediately, and on July 20

FIG. 1. SAMPLE TUBE-GRATE CELL

aging; black mineral froth began immediately to appear and to collect in large volume upon the relatively still water in the drag-belt trough. This rough froth-concentrate was found to assay over 40% copper; the product contained 35% insoluble, mostly in the form of coarse sand, mechanically suspended in the froth and easily separated by screening. It was found that 1% of the copper in the froth concentrate was in oxidized form, 22% of the concentrate was too coarse to pass a 100 mesh screen, and this portion carried only 0.87% copper, while the *minus* 100 mesh material carried 16% copper, 1.32% of which was oxidized, and but 16% of insoluble. The high grade of the froth concentrate was astonishing, showing that chalcocite and bornite predominated in it.

A few days later I made a bank of tube-grates, consisting of a parallel 1 in. pipes made up with return

the apparatus was tried with the colloid separator-line as feed, with the following remarkable result: Feed, 2.23% copper, of which 0.62% was oxidized; the concentrate assayed 20.4% copper, of which 1.18% was oxidized; the tailing carried 0.52% copper, of which 0.38% was oxidized, leaving only 0.11% sulphide copper as the rejection of the machine. This was an extraction of more than 70% of the total copper, and more than 92% of the available sulphide copper. This showed clearly that much could be expected in the application of the new process to Morenci ores.

The Canadian Consolidated Copper Co., in Sonora, Mexico, had been experimenting with the use of some Flinn-Towne pneumatic flotation units in its concentrating department. The plant had been shut-down on account of revolutionary troubles, and arrangements were made by Dr. Ricketts for the removal of one of these

TABLE 1. SCREEN ANALYSES. REDUCED FACSIMILE OF AUTHOR'S TABULATIONS.

units to the No. 6 concentrator at Morenci. The apparatus was installed under the direction of the Flinn-Towne people in the space reserved for flotation and was operated for several weeks with gratifying results as to recovery. These experiments demonstrated clearly that the flotation process would be suited to the saving of slimed copper sulphide in the Morenci ores. But the Flinn-Towne units were not of size suitable for use in the equipment of a large plant, or for the handling of large tonnages, except by using a great number of them. It was thought that their capacity could not be enlarged to advantage because of the difficulty with the air-emitting medium used, which was in circular-disk form with central discharge. These disks could not be made larger in diameter without increasing the difficulty coming from 'blinding' of the air-emitting surfaces through the lodging of coarse particles upon them, and from the formation of vortices by the larger volume discharged through the single opening in the centre, entraining froth with the reject.

The tube-grate idea previously tried in the drag-belt tank seemed to be a better way to admit air, because nothing could lodge upon the air-emitting elements to blind them, and constriction of the passage for the pulp and water would be avoided. This tube-grate idea therefore formed a basis on which to design units of large capacity for practical milling and especially to obviate the difficulty of limited space in the No. 6 concentrator. Accordingly, a tube-grate cell was installed in January 1915. This simple cell is shown in Fig. 4. It was used for some time to demonstrate the tube-grate idea and served as a 'cleaner' in the subsequent work done with a full-size machine.

The demonstration of the new

tube-grate cell was such a success that a three-stage machine, to have a capacity of 400 tons per day, called the C-B machine, was designed and made. Another one of the same kind and size was made concurrently for the Inspiration company, and both of them were started in operation early in March. The Inspiration machine, which is illustrated in Dr. Gahl's paper, gave good results, proving the design to be substantially correct. The Morenci machine was working in corrosive water, which formed a rust on the steel tubes and gradually closed the openings. The air-supply was found to be contaminated with grease and oil from the blower-bearing-

sulphide copper present in the feed, with an average for the period of 65%.

The blower was an old one borrowed from the mining department, where it had been used for ventilation. It was designed for not more than $3\frac{1}{2}$ -lb. pressure, and the developing of 6-lb. pressure deflected the shafts and caused the impellers to rub upon the sides of the machine, which had to be water-jacketed to keep down the heat developed. It was much larger than necessary, and a great excess of air was blown off from open valves. Therefore, no record of the amount of air used or power required could be made.

In spite of these minor difficulties it was proved: That flotation could be applied to these ores with great advantage; that the copper in the mill-tailing could be reduced to 0.50% (of which 0.25 to 0.30% was oxidized and beyond the reach even of

flotation); that this result could be improved by finer grinding in the Hardinge mills; that the same simple reagents used elsewhere would apply. Further, a new type of pneumatic flotation machine, well adapted to

FIG. 5. LONGITUDINAL SECTION OF C-B FLOTATION MACHINE. THREE CELLS IN SERIES.

FIG. 6. PLAN OF C-B FLOTATION MACHINE.

ings, muddy water entrained in the air, etc., which closed the pores of the filter from the inside. Some delay was experienced in overcoming these difficulties.

The C-B machine at Morenci made large volumes of rich froth and had become immediately profitable by reason of its being able to handle a large tonnage and save copper that would be otherwise beyond the reach of concentration. It was therefore kept in operation, even though working under the handicap of partly clogged tubes, blower troubles, etc. The daily tonnage handled during the month of April 1915 was from 125 to 390 tons per day, with an average of 269. The recovery made by the machine was from 45 to 79% of the

the conditions at No. 6 concentrator, had been successfully developed and its performance demonstrated on a full-sized unit. The new machine would not be in any way embarrassed by the oversize coming from Hardinge mills. All of the drag-belt overflow being handled by the colloid separator could go to a few of these new machines where all of the rich slined sulphide copper would be taken out. Or the whole tonnage of re-ground material produced in the Hardinge mills could go directly to the new frother in which the slined copper sulphides would be removed. The thoroughly frothed sand could then be treated on tables and vanners for the removal of the sulphide particles too coarse to be separated by flotation. Since there would then be no embarrassing losses in the slime part of the feed, these machines would work efficiently, and a maximum recovery would ensue.

After it became evident that flotation would apply to Morenci ores and before the value of the tube-grate idea was fully demonstrated, it was decided to install and experiment with a standard Callow flotation unit of

200-ton capacity, consisting of four rougher cells and one cleaner. This equipment was not received until after the full-sized C-B unit of 400-ton daily capacity had been installed.

The Callow equipment was started on May 24, 1915, and competitive operation proceeded for about three months. The recoveries proved to be much alike, although the feed was not identical. The Callow apparatus is not adapted to handle coarse particles of feed or oversize, and had to be protected by a screen or spitzkasten. It will handle about one-half the normal tonnage of the C-B machine, occupying the same floor-space. A summary of the results obtained for the months of May, June, and July 1915, also details showing the work for the month of July, are given in Tables 1 and 2. The performance is shown to be substantially parallel as to quality of work done, but quite different as to quantity handled.

As mentioned before, the consumption of air and power was not determined in the C-B installation because there was no way to take correct measurements. But the experience at Inspiration, where the C-B and Callow systems were also being operated in parallel, showed that the same amounts of air and power were used by each system.

Experience suggested wider launders for froth, larger 'cleaner' capacity, and simplified tube-grate construction of the C-B unit. These ideas are incorporated in

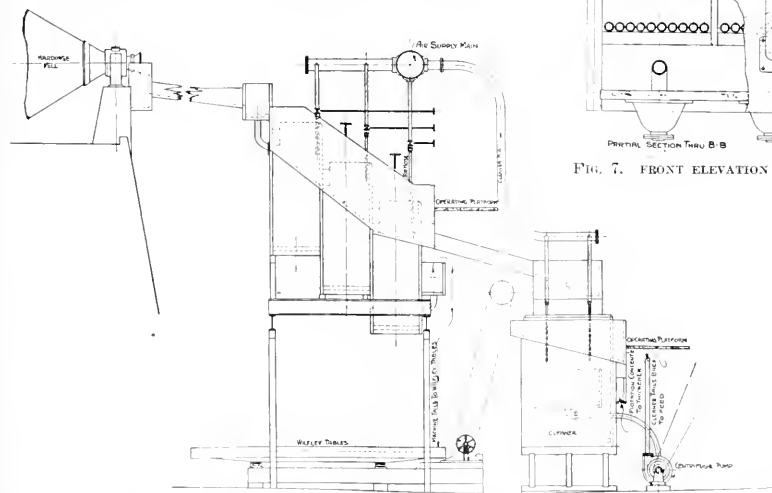

FIG. 8. ARRANGEMENT AT MILL OF CANANEA CONSOLIDATED COPPER CO., CANANEA, MEXICO, USING THE C-B 3-STAGE FLOTATION MACHINE.

the new design shown in Fig. 5, 6, and 7, in which it will be noted that the machine is merely a stationary wooden box suitably arranged to receive air-emitting tubes that are dropped from the top and rest upon ledges at the proper level in the pulp. These air-emitting elements are connected to the air-supply by the use of rubber hose. They can be taken out or put in without cutting off the feed or shutting down the ma-

chine, in case this should be of advantage. An air-pressure of 5 lb. is required. The air-emitting surface in the C-B machine is more than twice the complete cross-sectional area of the frothing compartments, and

FIG. 7. FRONT ELEVATION OF C-B FLOTATION MACHINE.

even if a ridge of sand should lodge upon the extreme top of the tubes and partly cut off the air-supply, the remaining unobstructed area would still be larger than the whole cross-section.

Fig. 8 shows the improved form with cleaners as arranged in the mill at Cananea, and is typical of the arrangement adopted for the later models. There are eight units, operated under conditions varying greatly as to quality of ores, there being a wide range of iron and copper sulphide conditions and all conditions of oxidation in the ore handled. The operation of the Cananea machines has been repeatedly interrupted by the internal strife in Mexico and no deductions of value are at present available.

Fig. 9 shows an application of the tube-grate idea to

a spitzkasten type of frother. One of these machines was made and installed in No. 6 concentrator at Morene, but was taken out before it was tried. It seems to embody advantages of much promise in a frothing-first flow-sheet and will soon have a trial to determine its value in the simplified concentration of ore that is amenable to flotation.

Without protection against blinding of the air emit-

ting media by sand or oversize, the C-B machine handled considerably more than three times the tonnage handled by the Callow in July, and did this without detriment to the metallurgical work.

IN THE WORLD'S HISTORY, the industrial epoch on which we are now well entered, has raised the most complex questions as to social and political relationships the human race has so far had to face. Unfortunately there are kaisers in industry just as there have proved to be in politics. The inevitable result in both cases has been war—in the one case for social and industrial freedom, and in the other for political freedom. Only enlightenment can create the co-operative, constructive spirit. But the enlightenment must be such as discriminates the large from the small, the principle from the detail, wisdom from mere knowledge. When, at last, we acquire wisdom as well as knowledge, we shall see that our industries exist for the benefit of all the people and not of the capitalist mainly; we shall see that the individual welfare can best be taken care of by caring for all; we shall see that capitalist and workmen are as inter-related as the parts of the human body; that neither is servant of the other, but that each is both servant and master; that we cannot injure the one without injuring the other; that we have here one of the highest problems the human mind has set itself to solve; that the best combined wisdom of all will be required to work out the best progressive solution of this greatest of industrial problems; that no solution of a problem of this nature will be final except in principle; that this is only one of those adjustments of human relations which must be continuous with the evolution of human society. When men have arrived at this broader view, they will become reasonable, just in proportion to the breadth of their view. We are safe in saying that centuries may be required in working out the solution to the industrial problem, since this is merely a problem in social evolution. Social evolution is merely the continuous adjustment of social relations to meet changing conditions. As long as these change, we must have the problem with us. It is easy to adjust the parts of a machine. But when each part is itself infinitely complex—is in fact a human being, whose adjustment in industrial relations must be self-adjustment—it is self-evident that any real mitigation of industrial ills must be founded on the gradual growth of intelligence and ethical feeling.—C. V. Corless in September *Bulletin* of Canadian Mining Institute.

Gold received at the San Francisco Mint during September totaled 184,827 oz., including 10,273 oz. of Australian gold and 245,702 oz. in sovereigns (£ or \$4.80 each). The value was \$10,022,263. Silver received amounted to 116,023 oz., worth \$97,825. Coinage consisted of 116,000 half eagles, 2,100,000 dimes, 2,100,000 nickels, and 1,700,000 cents, of a total value of \$912,000. Coin, bullion, etc., on hand at the end of the month totaled \$477,990,352.63.

FIG. 9. SPRITZKASTEN FROTHER EQUIPPED WITH TUBE-GRAPE AIR-FILTER.

Life On An Early Geological Survey

By H. Foster Bain

Yielding to the hypnotic influence of some fascinating sketches, I gave in 1910,* some account of early days up-on the Kentucky Geological Survey. I have never since wondered at Dickens having chosen to write of Oliver Twist. Indeed, at times, I have been disposed to believe that the people who boldly demand 'more' constitute a majority. My situation has become almost as desperate as that of the Colorado mine-promoter who once allowed one of his 'tunnel' companies to pay a dividend. He later confided to a fellow promoter that it was the most serious mistake he ever made, as it created a truly insatiable demand for more dividends and finally drove him out of business. Hoping that the results in this case may not be equally serious, I have made a further draft upon the supply of pictures that form the excuse for the existence of my text.

These sketches, it may be recalled, are reproductions of silhouettes, cut at the time by John R. Proctor, who, as a young man was a member of the party whose activities he has so cleverly depicted. They are published through the courtesy of Philip N. Moore, who, despite the many incidents of a busy professional career, finds place in his memory for the days when with A. R. Crandall, C. J. Norwood, Robert Peter, John Hussey, F. G. Sanborne, Lucien Carr, W. B. Page, W. W. Beckman, W. T. Page, and other young enthusiasts, all under the inspiration and direction of 'Uncle Nat' Shaler, he was helping to determine the material foundations of the present prosperous State of Kentucky.

The Survey was organized in 1873, and continuing in full activity till 1894, it contributed an enormous impulse to that industrial development of eastern Kentucky, in particular, that has marked the last quarter-century. Incidentally, the life on the Survey, the associations then built up, and the solid knowledge acquired in the course of the work, contributed also to the making of a number of useful careers in our profession. Even those who were members of the staff but a short time look back with pleasure and gratitude to their Survey days. It is a bit difficult for the historian, gazing at the massive structure and considerable atmospheric displacement of so vigorous a man as J. H. De Fries, for example, to realize that any member of the former corps was once considered to be "thin and puny-like" and in grave danger of an early demise unless a course of hardy outdoor life could be attained. Be that as it may, De Fries, the prosperous director of Borax Consolidated and trusted counsellor of London corporations, was, by report, saved to usefulness by the Kentucky Survey. As one gazes at certain other former members of the staff,

he inevitably wonders what they might have been except for those long days of tramping up valleys and over mountains and the nights of solid sleep that follow such days.

Any account of a geological survey party should properly begin with its most important member; and I leave it to any ex-survey man if, not the leader of the party, but the cook does not occupy that rôle. Many a bitter-scientific controversy has waged through the long years because the camp-cook failed at a critical time to keep the geologist well fed and in good condition, and so up

EXHIBIT A. THE SURVEY PARTY'S COOK.

to making accurate observations. I am more than half-persuaded that the numerous proverbs enjoining care on the man who would choose him a wife, grew out of the primitive condition where wife and cook were at best variant names for the same person. In the City, one can if need be, go to his club; or, if temporary difficulties as to the budget superimpose themselves on others domestic, there are the ever present Childs of A. B. C. restaurants, depending on which country you are in, to succor one. In camp in the mountains, one is dependent on his own resources and the tender mercies of a hired cook who probably, with a total disregard of distances involved, from time to time threatens to "quit and go home," unless his every wish be respected. Here is a secret worthy of consideration perhaps by those who frame courses in mining schools—a knowledge of cooking is the one sure road to independence. An engineer who can look the cook straight in the eye, conscious

*M. & S. P., October 1, 1912.

meanwhile of his own skill in flapping pancakes and getting the bacon and coffee just right, and can tell that cook: "Very well, whenever you like, but you had better think it over till morning"—that engineer, I say, is truly independent. He will have, and will deserve, a comfortable camp. It is, however, a risk, because, you see, the cook may take you at your word.

The cook for the survey party of which I write was

EXHIBIT B. BOTANICAL EXPLORATION.

Sam Tutt—fat, lazy and good natured as becomes a camp cook. I present his picture as Exhibit A. Sam was a native, and knew as a true Kentuckian how corn-bread should be made and bacon 'br'iled.' He even, in proper season, concocted wonderful pastry stuffed with the large ripe blackberries which make travel through Middle Western states a delight in summer. Those who have attempted pies in camp, need no higher testimony to his skill and will know at once why the Shaler survey of Kentucky was famous for the friendships formed within its staff.

It was the business of these early geological surveys to make complete studies of the natural history of the regions under survey. It was in the days before the intense specialization of the present, when a geologist, wandering off the edge of the well made topographic map furnished by the engineer, falls headlong into an

EXHIBIT C. EXPLORING CAVES.

abyss and must cry aloud for help to be set again upon his feet. In those primitive days the geologist had interest at least in botany, in entomology, and in kindred sciences. He could himself distinguish between a beech tree and a telegraph pole, and welcomed the help of the botanist who traveled with him and studied timber while he traced the coal beds. So the various scientists traveled the woods and hills together at times even hand in hand, or as nearly that as circumstances permitted, as depicted in Exhibit B.

Kentucky is a land of caves, and in both eastern and

western parts there are miles of caverns, some, as the Mammoth, in which untraced rivers tempt one to explore, others small and unimportant. One can never tell the size of a cave from looking at its mouth, and at the time of which I write, most of the secrets of the caves were yet unknown, the survey staff entered and explored such as they came across. Perhaps it is more correct to say some members did so, since in Exhibit C, Hussey the botanist and Norwood the geologist, seem to have chosen the wiser part, while Carr the archeologist struggles to regain his place upon the upper surface of the earth where men play at making history. One might question the result were it not that 'Uncle Jimmy' Kemp—whose accuracy and veracity the boldest would not call in question—has at various meeting of the Institute and Geological Society presented most convincing lantern slides of himself engaged in even more strenuous feats of climbing.

Every campaign finally closes, and every week of toil has its Saturday night, even in camp. These scenes depict conditions long before the days when the enameled tub so enthused the country guest that he "could hardly wait for Saturday night to come," but, as shown in Exhibit D, the differences between ancient and mod-

ern times are but differences in method and instruments. The essentials, plenty of cold water and a willing or at least acquiescent subject, being present, the result is the same. Even in recent years and at high altitudes in Colorado I have known ambitious graduates of 'Tech' to rig a hollowed half log so as to deliver spring water where it would do the most good.

The last scene, Exhibit E, illustrates a subject that

has ever been a favorite with painters—"After the Bath". While not done entirely in the modern French

EXHIBIT E. 'AFTER THE BATH.'

style, the sketch is still, I think, sufficiently realistic. It being well understood that beyond what Trilby immortalized as 'the altogether' there is nothing more to reveal, this will I hope, excuse me from making further research into the history and doings of the Second Geological Survey of Kentucky.

MINERAL PRODUCTION of Kentucky in 1914 was valued at \$26,668,474, slightly under that for 1913. The products include the following:

Clay products, tons.....	66,229
Coal, tons	20,382,763
Coke, tons	443,959
Fluorspar, tons	19,077
Mineral waters, gallons	437,334
Natural gas, value	\$490,875
Petroleum, barrels	502,441
Sand and gravel, tons	1,563,498

At about \$1 per ton coal forms the largest item in the list. The lead and zinc output is increasing, that in 1915 being 251 tons and 764 tons respectively, worth a total of \$213,006. The deposits are found in both central and western Kentucky. The presence of zinc-blende was recognized in 1854-'57 during the first geological survey of the State by D. D. Owen and S. S. Lyon.

In 1915 there was 370 tons of lead concentrate sold, and 2172 tons of zinc carbonate, the latter an increase of 1528 tons. At the Larue mine, near Marion in Crittendon county, low-grade sphalerite concentrate was recovered from dump ore. An experimental flotation plant was erected. In western Kentucky galena is associated with fluorspar, this being a continuation of the southern Illinois lead and zinc region. At present lead is a by-product of the fluorspar.

EXHIBIT D. 'SATURDAY NIGHT.'

Re-Timbering a Four-Compartment Shaft

By H. G. Thiele

Increasing pressure, due to heavy and swelling ground, was found to be gradually closing the Capote No. 2 shaft of the Cananea Copper Co. In some places the timbers had been cut out to the limit of safety in order to permit the passage of the skips. Besides interfering with rapid hoisting, there was always danger of a serious accident.

The new Capote No. 15 shaft was not ready for use, therefore, in order that production from the Capote mine might not be curtailed, it became necessary to re-timber No. 2 shaft with as little interruption as possible. This was done by dividing the work into two operations. Several months were required for the preliminary preparations while only a few days were necessary for the actual removal of the old timbers and their replacement.

The shaft was first plumbed to the 600-ft. level by letting down three plumb-lines from the collar-set at

to work after the night-shift had left the mine and hoisting had been discontinued. In this way they were enabled to work from 2 until 6.30 a.m. On entering the shaft they first built a temporary platform in the shaft, at the station below the point where they intended to work. This served to catch the rock and timber removed in setting back the lagging. Two men at work on the level below were able to remove the material dislodged and dump it into old stopes behind the shaft. In most cases it was necessary to chop out the old sheeting before it could be removed. Where the rock was hard it was necessary to drill and shoot short holes in order to loosen the ground. However, in most places it was soft and broken, so as to permit removal with a pick. In this way the shaft was enlarged about 18 inches, for the height of one set, around three compartments. Two

FIG. 1. PLAN OF SHAFT SHOWING POSITION OF PLUMB LINES.

surface, as shown in Fig. 1. The distance of the timbers from the plumb-lines was measured at intervals of every third set. These results when plotted gave a graphic record of the condition of the shaft. In one place it was found to be as much as 11 inches out of plumb. It was then decided to re-timber the three compartments used for hoisting men and ore, and to leave intact the fourth compartment, which contained the pipes and wiring.

The preliminary preparation for re-timbering consisted in tearing out the old sheeting and inserting new lagging 18 inches back from the shaft-timbers, as shown

FIG. 2. PLAN OF SHAFT SHOWING PONY-SETS.

in Fig. 2. This was done only in the three compartments that had to be re-timbered.

The work was done by a crew of eight men who went

FIG. 3. SECTION OF SHAFT BEFORE REMOVING SET C.

transverse timbers, Fig. 3 (A and A'), 5 by 10, were first set in place and blocked loosely against the wall-plates. After the lagging had been set in place, wedges were driven between the blocks and wall-plates opposite the posts. The same operation was done at the end of the last compartment except that the blocking was against the end plates. When complete the result was a short pony-set extending around three compartments. As the timbers were not to be removed in the pipe-compartment,

5 by 10 sprags were wedged between the wall-plates of every set a few inches back from the dividers. Short posts were wedged between the wall-plates opposite these sprags. Fig. 2 gives the plan of a set after the lagging had been set back. This operation should be conducted from the top of the shaft downward in order to prevent 'runs' of loose material into the shaft. All platforms and obstructions had to be removed from the shaft at the end of each shift, leaving it free for hoisting. Care and judgment were necessary so that the work might be left in condition to prevent all danger of loosening during the hoisting on the day-shift. Progress depended on the nature of the ground surrounding the shaft.

Several months were necessary to prepare the first 300 ft. of the shaft as just described. In the meantime the new timbers had been framed, each set and piece being numbered so as to facilitate handling in the shaft.

As work in the mine was usually suspended on the first and fifteenth of every month for pay-day, one of these intervals was chosen to begin the work of removing the old timbers and replacing them. Accordingly the first set above the brow-set of the 400-ft. station was chosen as the starting-point. In this operation the work must proceed from the bottom upward. It was first necessary to build a platform of planks in the shaft, level with the floor of the 400-ft. station. This was needed to prevent the material removed from falling into the sump. Temporary platforms were also built in the shaft above the 300-ft. station as a protection to the men working beneath that point. It was possible to lower one cage to the 300-ft. level. All the new timber had previously been lowered to that level, each set being piled separately.

Referring to Fig. 3, *B* was the brow-set and *C* the first set to be removed. The vertical stringers *V* and *V'* had been blocked in place in the middle of each set and at the end, as seen in Fig. 2, to hold back the transverse timbers *A* and *A'*. It was necessary first to remove the guides, which was done by withdrawing the lag-screws to the nearest joint below set *B*. The guides, and all other timbers subsequently removed, were lowered to the platform at the station below the point of removal and stored on that level.

In order to remove set *C* it was necessary to block up set *D* so that the shaft might not be loosened and break away above that point. In each compartment a 10 by 12 timber (See Fig. 4) was thrown across the shaft on top of the wall-plates of set *B*. On this was raised stulls *S* and *S'* supporting another 10 by 12 timber, which received the wall plates of set *D*. The stulls had to be set in the compartment in order not to interfere with placing the new wall-plates. The first set *C* was now ready to be removed. It was necessary to chop off the blocks before they became loosened sufficiently. In most cases it was easier to cut through the dividers than to attempt to loosen the blocks. Next, the posts supporting the set were sawed and chopped off in order to drop the set. The wall-plates were sawed a few inches from the dividers in the pump-compartment. As each timber was

loosened it was lowered to the station below and not dropped as that would have damaged the temporary platform. All was now in readiness for placing the first new set.

The wall-plates to facilitate handling had been framed in two sections, one length of which was equal to the

FIG. 4. SECTION SHOWING SET C REMOVED.

width of two compartments and the other to the width of the remaining compartment. All the joints and splices had been drilled for wooden pegs. The posts were lowered and set in their places on the old set (*B*), each having been cut to such a length as to bring the first set level. Next the wall-plates were lowered and put in place, after which the end plates and lastly the dividers. The set was assembled ready to be blocked. Plumb-lines were now dropped from above and the first set blocked to correspond to the collar set.

Before removing the next set *D*, it was necessary to support the set above, which was done by laying a stringer on wall-plates of new set *C'* and raising the stulls with stringer under the wall-plates of the set above *D*. Before removing the stulls supporting set *D*, short posts were placed on new set *C'* to receive weight of set *D*, while the transfer was being made. New vertical stringers corresponding to *V* and *V'* had to be inserted, reaching from new set *C'* to set above *D*. The short posts supporting set *D* could then be removed and a few blows would usually cause the set to fall apart. A new set was then assembled in place and blocked the same as the set below.

Replacing the station sets was a little more difficult although carried out by the same method as used in replacing the ordinary sets. Bearers were introduced at intervals of about 100 ft. and usually a short distance

below the stations. On completing the work the vertical stringers V and V' were all removed, as the transverse timbers A and A' had been securely blocked against the new sets. The sets were all framed from 10 by 10 Oregon pine of the best grade. The lagging was heavier than is usual.

A crew of 18 Mexicans, supervised by two Americans, worked on each shift. It was possible to remove and replace an average of two sets on each shift. The following distribution of the working crew was made: 8 timbermen working in the shaft; 3 men on station for removing timber and loose material; 3 for handling and lowering the new timber; 1 engineer for small air-hoist and 3

roustabouts for odd jobs such as bringing in sharp tools, drinking-water, and wedges. With an American crew two-thirds of the number could probably have done the work. A suggestion for avoiding delay, although it may seem obvious and insignificant, is the need of a sufficient supply of sharp tools always on hand. In the beginning more delays were caused by dull tools than from any other cause. Extreme care was necessary at all times in order to prevent accidents. Fortunately the work was finished without a single accident of any kind. The work was done under the direct supervision of R. Z. Hodges as foreman and Thomas Stanton as superintendent.

Gold Mining in War Time

In the last issue to hand of the 'Monthly Journal' of the Chamber of Mines of Western Australia, an interesting editorial has the above title. It has never been possible to carry on operations in the western State under as advantageous conditions as in the other States. The mines of the West are far inland, in an almost waterless and desert country, with little facility for the local production of foodstuffs. Gold to a depth of 200 to 300 ft. is oxidized, amenable to simple treatment; but the sulpho-telluride ore at depth requires special and costly methods. The standard of wages has always been high, rendered necessary by the high cost of transport, living, and other conditions. With depth the grade of ore has decreased from \$14.40 per ton in 1893 to well under \$9.60 at present, while the profit in 1903 was \$4.44 and today \$1.44 per ton. Large tonnages have to be treated now to make a decent return on the capital.

The War has intensified all of these factors, added to which was the difficulty in securing such supplies as zinc sheets, explosives, lead acetate, quicksilver, cyanide, and special parts of machinery, none of which were made in Australia. The Chamber of Mines took prompt steps to secure supplies, and these are now arriving regularly. The great benefit of the Chamber's organization has been proved, for if the companies had acted individually many would have been forced to suspend work. The following shows increases in some of the mine supplies:

Per cent increase since the War

Manila rope	25.0	Cement	52.7

Bicarbonate of soda ..	13.4	Zinc shavings	85.2
Galvanized iron	64.0	Cupel material	13.1
Steel plates	42.6	Bar iron	48.0
		General hardware	20 to 25

Oils have advanced from 3 to 4 cents per gallon. In June, 1914, one mine at Kalgoorlie had stores costing \$14,900; a year later these cost \$17,800. Since the latter date there have been further advances in prices.

Many of the best men employed at the mines have gone to Europe, resulting in a shortage of labor. The Unions

acted foolishly regarding certain unnaturalized foreigners at the mines, which re-acted against the labor supply. Increases in wages are being demanded. The general result of the labor attitude was to reduce the output of nine large mines at Kalgoorlie by 5300 tons and \$32,000 gold weekly. The monthly output of this district is nearly \$1,100,000 from 132,000 tons of ore. The total to date is over \$300,000,000.

Additional taxation is another grave disability. Mining raised Western Australia from poverty, obscurity, and stagnation to prosperity, prominence, and progress. The State and Federal governments are making undue levies on the mining industry, which is willing to bear its fair share. Impositions consist of the State income and State profit, and Federal income and Federal land taxes. In addition to these the Commonwealth government has a bill to levy a war-profits tax. This requires 50% on all profits that exceeded by more than \$960 the normal standard of profits made by any business prior to the War, calculating an average of three years preceding August, 1914.

Western Australia has produced gold worth \$577,000,000, of which \$124,000,000 has been paid in dividends.

THE COST OF OPERATION has been much higher during the past six months. Wages have been advanced, and an eight-hour day introduced at all points. The cost of materials has been advanced 50% and, in more than one instance, over 100%. On this account the profits per ton of ore smelted, or bullion refined, has been seriously reduced, due to the fact that the toll received from the mines and smelters has been fixed on long-time contracts, made when present costs were not believed possible. The present favorable showing as to profits is due, partly, to a large and abnormal increase in business, but, to a great extent, to the production of A. S. & R. Co. mines and to new lines (tin) of business in which the company has interested itself, and which, it is hoped, will be increasingly profitable. A few years since, the business of the company was almost entirely the smelting of lead and silver ores, and the refining of the resulting bullion. This portion of the company's business has been far less profitable per ton of materials handled than during the same period of last year.—Abstract from half-yearly report of A. S. & R. Co.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

A SCARF SAMPLE is one that is taken over the full width of a vein by cutting a groove across the face of it.

SULPHATE OF ALUMINA is used for clarifying water. Present quotations are from \$120 to \$185 per ton.

USING A FUSE with its detonator to bind together sticks of powder into a bundle is a very dangerous practice, although not uncommon.

CARBONIC ACID GAS pockets are encountered in magnesite mines, and have been known to result in suspension of work in that ground until cleared by other openings.

OIL CONSUMPTION in calcining refractory magnesite ore in Sonoma county, California, is one barrel per ton of calcined product; or one barrel for two tons of crude ore, as practically half of the ore is carbonic acid gas.

MAKING WIRE is one of the oldest of the metal arts. The first wires were rolled from thin strips of metal. Wires of gold and silver have been recovered from the graves of the ancients in Asia, Africa, and in South America.

WELL-EQUIPPED MACHINE SHOPS are of importance to large dredging companies, most of which in the United States are so equipped. The Conroy company at Ruby, Montana, spent \$50,000 on its shop, where 24-ton parts are repaired.

PORTLAND CEMENT for underground work is used in increasing quantities. It has been utilized recently to close water-channels in wet ground, by forcing cement into the rock in advance of the drills by means of a powerful pump.

SPARE PARTS for repairs must be always ready to install on dredges. Most of these are heavy and expensive. The Conroy company, at Ruby, Montana, finds it necessary to keep on hand at least \$60,000 of material for its large boats.

CEMENT produces a peculiar skin eruption, resembling the itch. It is caused by the alkaline content of the concrete acting on the skin, especially where already softened by water. Covering the skin with fat or grease and careful washing will largely prevent the inconvenience.

PLATINUM will not amalgamate with quicksilver alone, but will if sodium is added. In ordinary quicksilver amalgamation, the flakes of platinum float on the surface and can be removed. If sodium is used the platinum may be separated from gold by agitating the amalgam with water until the sodium is used up to form sodium

hydroxide, when the platinum will come out on the surface of the amalgam, provided, of course, that it is sufficiently liquid.

LIQUIFIED CHLORINE GAS, obtained by great compression, or by intense refrigeration, has become an important article, which can be transported in strong steel cylinders. Its main use is in the manufacture of tin chloride by the Goldschmidt process for reclaiming tin scrap.

NICKEL in considerable quantity, probably between 700 and 1000 tons, is produced as a by-product in the electrolytic refining of copper in United States. Most of the metal is produced in the pure state by electrolytic processes although a great deal is marketed as nickel salts for use in plating.

CONSTANT ATTENTION should be given to mine-ladders. Frequent inspections should be made to see that the fastenings are secure and that there are no loose or broken rungs. Care should be taken to see that pieces of broken rock do not become lodged behind the rungs where they may be loosened and fall on the men using the ladder-way.

Lack of proper illumination causes from 10 to 25% of all industrial accidents. The approach of winter makes it necessary to overhaul surface-lighting apparatus at mines and mills, which, during the summer months, is not used as much. A well-lighted corner prevents accidents, and is more comfortable for employees to work in.

FOREMEN at the Ford motor factory, Detroit, are not allowed to discharge men. According to D. S. S. Marquis, head of the educational department, taking this right away from foremen is the greatest thing they ever did at the works. From June, 1915, to August, 1916, there were hired 21,663 men. Of these, 5680 left, and only 5 were discharged.

A HOISTING ROPE in use is continually subjected, not only to the wear of the drums, sheaves, or rollers, but also to a constant wear and friction on the inside, due to the wires in the strands moving slightly when the rope is bent. To be of value the lubricant should not only penetrate to the centre of the rope, but should also thoroughly coat the inside wires.

MOLTEN COPPER is transferred from converters to casting machines in cast steel ladles lined with fines screened from ores regularly used as converter fluxes at the Arizona Copper Co.'s smelter. Bars are cast in molds made of converter copper. A 1½-in. cast-iron splash-plate covers half of the bottom area, and an average of 73 tons of bullion is cast per mold. Bars weigh 240 lb. each, and 35 minutes is required for casting a charge weighing seven tons. Considerable chipping of bullion bars is necessary to remove edges and fine shot due to blowing to gas finish of 99.60% copper.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

REDDING, CALIFORNIA

NOTES ON SHASTA AND TRINITY COUNTIES' ACTIVITIES.

After a series of experiments extending over eight years, the Bully Hill Copper Co. has devised an electrolytic process for recovery of zinc from the complex copper-zinc ores of the Shasta copper-belt. The unit in commission at Winthrop has demonstrated the commercial value of the process, which will be utilized in the large plant that the Mammoth Copper Co. is constructing near Kennett. Metallurgists from Broken Hill, Australia, are at Winthrop studying the system for probable application on the zinc concentrate of that centre. Experiments indicate the process will extract zinc and other metals from the fine dust deposited in the bag-house of the Mammoth smelter.

The Mammoth smelter is reducing approximately 1200 tons of material daily, of which 900 tons is ore, including 300 tons smelted for the Balaklala company. The Mammoth ore averages 3 to 5% copper, about 4% zinc, and \$1.50 to \$2 gold and silver per ton. Considerable high-grade zinc has been opened recently in the Mammoth mine. Driving of the Mammoth and Friday-Lowden tunnels is making good progress. The tram to the smelter from the Stowell mine has been completed. Arrangements have been made for building a new boarding-house and other structures.

REDDING. The accompanying photograph shows a new Union Iron Works dredge constructed on Clear creek, 5 miles from

As soon as the old workings are repaired vigorous development is to be done. Much ore is believed to exist in old workings.

The first payment on the Bell Cow gold mine, on Arbuckle mountain, has been made by T. F. Ames, Mrs. Frank A. Greene, James Long, and Frank A. Greene. The new owners started work about two years ago, and have opened a strong vein of medium-grade, free-milling quartz. Mill tests have proved satisfactory. The mine is near the road between Redding and Harrison Gulch.

Gold-dredging in Trinity county is steadily gathering importance. The new boat of the Pacific Dredging Co. is rapidly nearing completion at Carrville, and is scheduled to go into commission within 40 days. It is equipped with buckets of 9.5-cu. ft. capacity, and will operate in Morrison gulch. The company continues to prospect large areas with drills, and has proved a broad acreage outside of the main holdings. Near Junction City the Valdor Dredging Co. is completing a large dredge. The dredge of the Trinity Mining Co. is working steadily near Lewiston. A number of dredging projects are receiving consideration in other sections of the county.

The Hess gold mine in the Hess district, a few miles from Alturas, has been equipped with a small mill that is said to be making an excellent recovery. Development has attained a depth of 200 ft., and near this point the main vein is about 18 ft. wide, with the quartz averaging \$10 per ton. Work has been started to open the vein at a deeper point.

NEW DREDGE NEAR REDDING, CALIFORNIA.

Redding, for L. Gardella of Oroville. The buckets are of 7½ cu. ft. capacity, and are of manganese-steel. The boat is arranged to dig 35 ft. below water and has a capacity of 125,000 cu. yd. per month.

The Michigan copper claims, near the Bully Hill mine, are being operated under bond by M. E. Dittmar of Redding, and San Francisco associates. L. C. Monahan is in charge. A good quantity of shipping ore has been extracted, and promising ground is under development. The Michigan has been idle several years, but at one time produced much ore of good grade. Some work is going on at the Arps, Shasta Belmont, and other properties in this district. The ores contain considerable zinc, and the Bully Hill electrolytic process is expected to revolutionize mining throughout the east-side field.

The Minnesota copper mine, between Iron Mountain and Keswick, has been re-opened by Denver people after several years' idleness. George F. Graves has been placed in charge.

SUTTER CREEK, CALIFORNIA

LABOR.—OLD EUREKA, BUNKER HILL, AND KENNEDY.

A meeting of the striking miners was held here on Friday evening, the 6th, when one of the walking delegates of the Union used all his powers to convince the men that success awaited them if they would continue to hold together and that the mine-owners could not long withstand their demands; but it appeared that his remarks did not find favor among the men present, as Union men and others began leaving the hall long before he concluded his remarks, and when he had finished only three men remained in the hall. It is stated on good authority that the South Eureka men will return to work on the old basis on Tuesday morning, the 10th.

The shaft at the Old Eureka has been unwatered and repaired to a depth of 750 ft. An extra crew started on October 8 at construction work. The new steel head-frame is now to be erected, as the work of laying foundations and grading for same has been completed. The new double-drum hoist and other modern equipment will be the means of much better headway being made in the shaft-work from now on. An encouraging discovery was made during the week when men engaged in cleaning-out a drift on the 500-ft. level uncovered a vein of good-looking ore. The vein pitches south toward the Central Eureka ground, and where opened is about 5 ft. wide. This would appear to prove the truth of rumors afloat concerning the good ore left in the mine when early-day methods made it unprofitable to extract ore that now pays dividends.

At the Bunker Hill mine near Amador City, 17 men are working in the shaft completing repairs, and a number of others are engaged in erecting concrete ore-bins and making other improvements of a permanent nature at the collar of

the shaft. Masked men, supposed to be striking employees from that mine, have stopped others on their way to work there during the week, and ordered them not to work. R. Christiansen, the foreman, has been sworn in as a deputy-sheriff, and now accompanies his men to and from work. Some of the shaft-men claim that attempts have been made to photograph them on their way to the mine, and they think that this is a move on the part of the strikers for the purpose of future identification or blacklisting in Union camps. No violence has been undertaken since sheriff Lincot and U. S. deputy-sheriff Hartz have shown their ability to cope with the situation. The trial of two men who are accused of attempting to injure employees has been postponed until Saturday, the 11th.

At the Kennedy mine, three large new boilers are being installed, so that when the men resume work there will be no need of laying them off for this purpose. The superintendent, of the Kennedy, Webb Smith, and N. S. Kelsey of the Argonaut, have each expressed themselves as willing to commence operations as soon as a sufficient number of the men show a disposition to resume work, so it is hoped that work will soon be in progress all along the Lode.

In the Pine Grove district there is more activity than usual. R. Robinson has just finished cross-cutting a wide vein in the Reward mine. It is about 25 ft. wide, 8 ft. of which is good ore. The Pine Grove Mining Co. started its little mill during the week, and by continued stoping the management expects to mine sufficient ore to keep the stamps dropping steadily.—A large body of high-grade ore has just been opened at the Kerckoff mine above Defender; while some good-looking ore has been developed in the mine on the old Stirnman homestead.

TORONTO, ONTARIO

PORCUPINE, KOWKASH, AND KIRKLAND LAKE DISTRICTS.—MOLYBDENUM.

The Hollinger Consolidated at Porcupine is planning to effect a reduction in haulage costs by the adoption of the flow system with underground bins when the central shaft is in operation next spring. The ore will be carried in trains driven by electric locomotives along the haulage-level to the main shaft and tipped into 750-ton loading-pockets, from which it will be drawn-off and the large lumps crushed, and then be raised in 5-ton skips. At the top of the shaft the ore will be dumped into crushers, and after being reduced will drop into 500-ton storage-bins cut out in the hillside adjacent to the central shaft. From storage it will pass by an inclined tram to the top of the mill and be distributed to the stamp feeders. This system will utilize gravity to the greatest possible extent, and will also avoid the necessity of building and heating outside storage-sheds.

At the Davidson the main vein on the 300-ft. level is fully 15 ft. wide, showing visible gold ore, and the ore has been cut and cross-cutting started at the 300-ft. level.

Shareholders of the Apex have voted a dividend to issue \$100,000, half of the per share to come from the development, and the other half from the operating account.

A new vein 15 ft. in width has been found in the Newray east of the shaft, making the total discovered since operations were resumed.

A contract has been let for level 220 ft. and level 240 ft. diamond-drilling on the Thomas Hannah claim.

Development continues at Tebota, and Kowkash, by the Porcupine Gold Mines, Ltd., which owns 24 claims in the Tebota district, in addition to one (600 ft.) the King Pool and two properties at Kowkash. On the Apex claim, Tebota, a new vein has been discovered, 15 ft. wide, and 25 ft. deep, carrying low-grade free gold, and a great deal of pyrite, which is being treated on the surface. On the Davidson Mine the vein 15 ft. wide at the top of the

an 18-ft. shaft. Diamond-drilling has proved the vein at a depth of 125 ft., where it has widened considerably. Some additional discoveries have been made on the King Dadds property, and adjacent claims are being prospected by the Tash-Ori to pick up the original discovery vein.

The Lake Shore Co. of Kirkland Lake, will finance the erection of a 100-ton mill by the issue of 150,000 shares of treasury stock, making the third mill in the district.—The vein found on the McKane property at Kirkland Lake, under option to the Beaver, at the 300 ft. level is 40 ft. wide and will average about \$9 to the ton. A 12-drill compressor plant is being installed.

A rich gold discovery is reported at Bourke's station, mile 181, on the Temiskaming & Northern Ontario Railway. A settler named Anderson uncovered the vein when clearing his farm. It is rich in free gold and has been traced a considerable distance. The announcement of the find has resulted in a rush of prospectors to the neighborhood.

As a result of the demand for war munitions, molybdenum extraction appears likely to take an important place among the mining activities of Ontario. On September 21 the first ferro-molybdenum commercially produced in Canada was run at the plant of the International Molybdenum Co. at Orillia, where three furnaces are now in operation. The Hamilton Molybdenum Alloys Co., Ltd., capitalized at \$500,000, James Harris, president and managing director, is putting in modern machinery for the development of Hamilton mine No. 2 near Norland, Haliburton county, and anticipates putting molybdenite on the market at an early date.

The following notes are part of the half-yearly report of the Ontario Bureau of Mines, the first half appearing last week:

COBALT. With the outbreak of War the European market for cobalt oxide was suddenly cut off; however, new markets and new uses for metallic cobalt have improved the situation. High-grade steel is now produced, using cobalt alloys. Metallic cobalt production is greatly in excess of last year.

NICKEL. Metallic nickel from cobalt ores is produced at the refining works of the Deloro Smelting & Reduction Co., formerly known as the Deloro Mining & Reduction Co. The output shows an increase over that of 1915, which was not marketed during the six months' period.

NICKEL COPPER MATTE. The smelters of the Canadian Copper Co. at Copper Cliff and the Mond Nickel Co. at Coniston are turning out nickel-copper matte at an unprecedented rate. The production, as compared with the first six months of 1915, shows an increase of nearly 40%. The valuation of the metallic-contents of the matte has been made on a basis of 10c. per pound for copper and 25c. for nickel. The figures given for metallic copper and nickel separately show that the prices were over 18 and 12c. per pound, respectively. The British America Nickel Corporation is soon to start at Sudbury.

In addition to the above mentioned companies the Alexo mine, near Porcupine Junction, produces a small amount of nickel-copper ore, which is treated at the Coniston smelter.

MOLYBDENUM. This mineral occurs widely in Ontario, but is mined chiefly in Renfrew county. It is required at the present time for use in the manufacture of high-speed tool-steel, and for this purpose molybdenum will probably replace tungsten to some extent. The demand for molybdenum steel to be used in munition factories comes largely from the Allied nations—Britain, France, and Russia. Molybdenite concentrates containing 85% or more of MoS₂ are worth about \$1 per pound. Ferro-molybdenum is now (September) being manufactured for the first time in Canada by the Orillia Molybdenum Co. at Orillia and the Tivani Electric Steel Co. at Belleville.

IRON. At the Porcupine, the only shipments of iron ore were from the Alexo mine operated by the Algoma Steel Corporation of S. O. Ste. Marie. Although iron-ore production shows a decrease compared with the same period in 1915, that of the iron shows a material increase, both in tonnage and value.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU. In its issue of Sept. 25, *The Alaska Daily Empire* includes an additional 40 pages comprising its 'Development' number. The matter is of considerable interest. Special articles include 'Mining and its Bearing on the Future of Alaska,' by B. L. Thane; the 'Alaska Juneau Gold Mine,' by P. R. Bradley; 'Mining Development in Alaska,' by William Maloney; 'Development at Treadwell'; and 'Water Power of Alaska,' by C. L. Andrews, followed by interesting notes on the great fishing industry, furs, agriculture, scenery, the development of Juneau, Skagway, Douglas, transportation, the proposed Gastineau Channel bridge, and education.

August returns from the mines on Douglas island were as under:

	Alaska Treadwell	Alaska Mexican	Alaska United
Broken ore in stopes, decrease or			
Increase, tons	- 9,842	- 5,411	+ 10,056
Stamps dropping	120	150	300
Time worked, days	20.31	30.67	30.61
Ore crushed, tons	13,160	24,696	29,889
Gold from all sources	\$30,538	\$78,196	\$102,900
Yield per ton	2.32	3.16	2.10
Operating profit	13,772	32,997	14,618
Construction charges	4,606	17,585	14,485
Other income	3,730	11,281	3,730

The Treadwell company reports that on July 27 surface evidences of a hanging-wall subsidence near the Treadwell-United-700 Ft. Claim boundary-line began to be manifest, and therefore it was deemed advisable to discontinue the heavy drawing on reserves of caved and broken ore in order to protect the future of the Treadwell, 700, and Mexican mines. The drawing of this ore had been particularly heavy in the Treadwell mine for the reason that the development done on the 1950, 2100, and 2300-ft. levels has so far found very low-grade ore, verging on the limit of being profitable or not. This protective action has necessitated the shutting-down of the 240 mill and half of the 300 mill, on August 1. The time run by the 240 mill in August was 10 hours and 34 minutes, to clean-up the ore that was left in the bins after tramming of ore to the mill had ceased. The power used for the time run was electricity. On August 1, operation of the 300 mill was reduced to 150 stamps, the time run being 30 days, 16 hours, 3 minutes, of which water was used for power 16 days, 7 hours, 31 minutes, and electricity 14 days, 8 hours, 32 minutes.

During September the Alaska Gold Mines Co. treated 135,750 tons of \$1.30 ore. Heavy storms interfered with haulage of ore.

KNIK. The Talkeetna Mining Co., of Seattle, is building a mill on its mine near Knik. The company ordered by wire from the Denver Quartz Mill & Crusher Co. a quartz mill and feeder. This is the third shipment of Denver quartz mills to leave Denver for Knik during the past 12 months.

NOME. New York people have formed the Alaska Mines Corporation to acquire the ground and dredges of the Nome Consolidated.

WRANGELL. The Bon Alaska Mining Co. has been financed, and grading for a 10-mile railway, from the mouth of Mill creek, which empties into the sea 10 miles from Wrangell, to Groundhog basin, is to be started. The mine has a good deal of gold, silver, lead, and zinc ore developed, and next spring shipments of 600 tons daily are contemplated.

ARIZONA

In Bulletin 29 of the University of Arizona Bureau of Mines, Allen T. Bird describes the resources of Santa Cruz county in 27 pages. The earliest mining known on the Pacific Slope of the United States was done in this region, which has witnessed events of historic interest. The greatest length of the county is 50 miles, and width 30 miles. Two branches of the Southern Pacific pass through. Wagon-roads are being improved. The mountain ranges vary from 5000 to 9000 ft. in height, the highest peak being 9432 ft. The principal mining districts are the Nogales, Patagonia, Palmetto, Harshaw, Red Rock, Wrightson, Tyndall, Greaterville, San Cayetano, Pa-

FOUNDATIONS FOR TWELVE 48-IN. SYMONS FINE DISC-CRUSHERS, TO CRUSH 5000 TONS OF 3½-IN. ORE TO ½-IN. MESH IN 16 HOURS, AT THE CORNELIA COPPER MINE, AZO.

jarito, and Oro Blanco. Igneous and sedimentary rocks occur in great variety. The veins carry gold, silver, lead, copper, zinc, tungsten, and molybdenum. Early development resulted in production of lead and silver; copper increased with depth. In the Patagonia mountains there are large deposits of copper-bearing porphyry, one being at Red Hill at the north end. The Duquesne Mining & Reduction Co. at Duquesne, 3 miles north of the Mexican border, is treating zinc-copper ore by flotation. In the Patagonia district are 40 promising groups of mines, some producing. In the Palmetto district are the Three R mines, which have yielded a lot of high-grade copper ore. In the other districts are many mines with good futures.

CHLORIDE. According to Frank Stoffee, who recently completed a mill for the Butte & Arizona company on Stockton hill, he has completed arrangements for construction of a 500-ton mill at Chloride. This plant will act as a custom mill, treating old dumps and current ore from the mines.

GLOBE. Eight to ten per cent copper ore has been opened on No. 16 level west in the Old Dominion. The ore is oxidized.

MIAMI. Erection of steel for the additional two units at the Inspiration mill is finished by the Kansas City Structural Steel Co. The residue is filling the dam across Webster gulch so that before long another lot of launders must be erected.

The following statement has been issued by the Miami Copper Co. regarding the suit of Minerals Separation for infringement of patents in the flotation process, which suit was decided against the Miami: "The bulk of our recovery of copper

is by table concentration. The decision only affects a comparatively small additional saving that is made by flotation, and our counsel are confident this decision will be reversed in higher courts."

ARKANSAS

FORT SMITH. The Arkansas Zinc Co. has decided to add another block of retorts, 800, to its present three blocks of 2100 retorts.

MURRAY. Great things are expected of this zinc district in Newton county. Ore is found at the surface, and is easily mined.

CALIFORNIA

The State Water Commission has been asked for permission by L. G. Sinaard and C. E. van Barneveld to appropriate for hydraulicking 100 cu. ft. of water per second from Slate creek, a tributary to North Yuba river in Plumas county. The proposed ditch will be over 18 miles long, connecting with the Neocene Placer Mining Co.'s Cleveland ditch. The water will be returned to the river.

REDDING. The Potosi gold mine, 6 miles west, after being idle since 1871, is being re-opened in charge of A. S. Howe. The property belongs to the estate of the late Senator J. P. Jones of Nevada.

SAN DIEGO. In view of the interest in metals entering into war supplies, two concise reports, written by F. C. Calkins of the U. S. Geological Survey, on molybdenite and nickel ore in San Diego county, are timely. Mr. Calkins describes clearly the modes of occurrence of the ores and gives helpful suggestions for further development work and prospecting. The molybdenum prospect is in a dike of fine-grained (aplite) containing an average of much less than 1% of the mineral molybdenite (molybdenum sulphide). Only one prospect has been located so far, but the surrounding country is favorable for the discovery of others. The nickel deposit is an irregular body in a dark igneous rock (gabbro) and is shown by Mr. Calkins to have an origin similar to that attributed by most geologists to the famous deposits at Sudbury, Ontario. The nickel occurs in an iron-nickel sulphide (probably polydymite) and assays of more than 1% of nickel have been obtained. Copper is also present in quantities ranging from a trace to 2%, and conditions are favorable for the presence of platinum.

(Special Correspondence.) Development at the Addis & Harral mine near Soulsbyville is progressing satisfactorily. A hoist and compressor are being installed. Sinking is under way on a 1-ft. vein of good ore. The Red Jacket mine in the Rio Oak Flat district is under lease and bond. The property is in charge of Mr. Mont Omery. J. L. Whitney, general manager of the Atlas mine near Tuttle town, has bonded the Boltano mine at Greendale. Extensive development will soon be started. E. H. McMahon county assessor, has opened a promising asbestos mine near Kashida. Samples brought to Sonora show exceptionally long fibers which will make a first class commercial product. At the Harvard mine near Pine town, 60 stamps are crushing continuously.

Sonora, October 1.

COLORADO

CENTRAL COLORADO. Gold output of the district in September was as follows:

Plant	Tons	Average Grade	Gross Value
Golden Eagle	21,000	\$18.00	\$366,000
Pack and	12,164	14.75	166,166
Portland	1,700	9	12,560
Summit	1,500	10	12,500
Island	1,000	16	28,000
Worship Rock	1,000	14	24,000
Total	38,364	\$14.66	\$519,226

This is 21,000 tons less than in August, due to the temporary shut-down of the Portland-Independence, Rex Caley, and Reed mills, which treat low-grade ore.

The Vindicator Consolidated will pay the regular quarterly dividend of 3% and an extra of 3% on October 25.

LA PLATA. The upper and lower districts are busy extracting ore and preparing for the winter. Some mines have shipped rich gold and silver ore.

LA VILLE. Miners here have asked for an increase of wages from \$3.75 to \$4.25 per day. A conference is to be held with the mine managers.

ORAY. The recent development in the Governor mine in the Mt. Sneffles district is producing better ore than expected, and the snaffles have recovered 138 oz. of gold from 4000 lb. of ore.

IDAHO

BURKE. At its Gem mill and at the Federal mill the Hecla company is treating 450 and 300 tons daily, respectively. Additions to the former plant will increase the capacity by 200 tons.

GILMORE. The Pittsburg-Idaho Mining Co. is receiving bids for a new electric power-plant, also hoist, compressor, pumps, etc. An oil-engine is to drive the generator. A. S. Ross is president. Ore shipments in September returned \$57,867 at a smelter in Utah.

KELLOGG. Grading for the Bunker Hill & Sullivan smelter is finished and concrete foundations are being poured.

PINE CREEK DISTRICT. The Constitution Mining Co. is to spend \$26,000 in new plant, to be ready by January 1. A contract for a 100-ton mill has been let.

Unusual activity prevails among the mines of the Pine Creek district, an incentive to development having been given by the belief that the railway lines will be extended to provide transportation for the region.

WALLACE. In the suit of the Alameda Mining Co. v. the Success Mining Co. before a referee, testimony in the accounting case closed on October 3. There is a wide difference of opinion regarding the value of the ore alleged to have been wrongfully mined, varying from \$168 to \$147,761.

MICHIGAN

THE COPPER COUNTRY

DOWAGON. Six of the Calumet & Hecla subsidiaries are now paying dividends, the C. & H. receiving \$2,226,908 so far this year as follows: Ahmeek, \$1,225,600; Allouez, \$287,000; Centennial, \$41,500; Isle Royale, \$98,730; Osceola, \$524,000; and Superior, \$50,078. In all of 1915 the Ahmeek paid \$563,776, the Allouez \$41,000, and the Osceola \$262,000; and in 1914 the Ahmeek paid \$147,072, and the Osceola \$98,250. The C. & H. and properties under its control are employing 12,000 men, 4000 of whom are with the C. & H., which treated 250,000 tons of ore during September.

MONTANA

BUTTE. The Boston News Bureau gives the following information: The Atlantic Mines Co., which three years ago took over the La France Copper Co. property, has been dissolved, and all the property save the cash on hand will be offered for sale at public auction in Butte on November 1, following which a dividend in liquidation will be distributed. The Anaconda company has offered a price for the property which will return Atlantic stockholders the \$250,000 cash originally in the company's treasury when operations started, and a sum equal to the par value of the stock \$10 together with 8% interest per annum, a total of about \$12.50 per share. La France mine was worked about 20 years ago for silver without success, and was closed for several years. Recent work has demonstrated that the principal value, if any, which may be found in the ores, is

in the zinc-content. Heretofore it has been impossible to treat these ores, but the electrolytic process has solved the problem.

The North Butte company proposes to do 3500 ft. of development each month. The Granite Mountain shaft is down 3300 ft., the deepest at Butte.

The Ballaklava is shipping 100 tons of 3% ore daily. A shoot was cut last week at 2600 ft., 30 in. wide and containing 6% copper.

At 1000 ft. the Butte & Zenith has commenced cross-cutting south and north.

On the 1600-ft. level of the Butte & London a manganese-quartz lode, assaying 10 oz. silver per ton, has been cut. It is 35 ft. wide.

The total pay-roll at Butte for September was \$2,189,000.

HELENA. To treat low-grade ore from the Helena district the New York & Montana Testing & Engineering Co. is to spend \$30,000 on a custom plant. C. E. Fryberger is in charge.

SUPERIOR. The Intermountain Copper company will pay its second dividend, of 3c. per share, on November 20. The new 100-ton mill is working well. The product is sent to the B. C. smelter at Greenwood.

TROY. The new 300-ton mill, 1500-hp., hydro-electric plant, and 5½-mile railway, being constructed near here by the Snowstorm company, are nearly complete. The mine contains 400,000 tons of ore assaying 7% lead, 8% zinc, and 3 oz. silver per ton. A recovery of 85 to 90% of the first two metals is expected, and 40% of the zinc. Slime is to be treated by flotation. The Banner & Bangle vein has been developed by 6 adits for 2500 ft., with a vertical depth of 1100 ft. Production is expected to start early in November.

NEVADA

GOLDFIELD. The Silver Pick shaft is down 930 ft., in the shale. The mineralized quartz passed through was 30 ft. thick. No. 2 drill-hole, sunk from the 500-ft. level, reached a depth of 1400 ft. It cut three gold-copper veins which will be opened by subsequent development.

At a depth of 1017 ft. in the Jumbo Extension, near the boundary of the Velvet claim and the Jumbo Junior, a new ore-channel has been opened in the shale. While of low grade this formation is encouraging.

Three rich shoots have been opened at 300 ft. in the Great Bend.

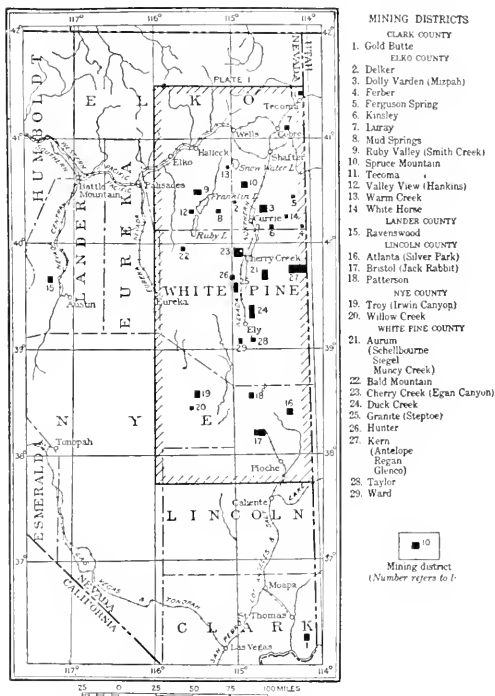

TONOPAH. The Miners' Union is to ask the Mine Operators' Association for an increase of 50c. per day while silver is at the present price.

YERINGTON. During the quarter ended June 30 the Nevada-Douglas company's revenue was \$105,936 from ore and \$88,936 from assessments. In the half-year the profit was \$11,044. During the past 60 days the mill has treated 75 tons daily, recovering 85% of the copper. Six towers, 40-ft. diam. and 20 ft. high, holding 750 tons each, are being erected to leach 3-in. oxidized ore. Sulphuric acid is to be used.

The Mason Valley Mines Co. has issued a report, in which it is stated that the directors will try and raise \$1,000,000 by selling 200,000 shares at \$5 each.

In Bulletin 648 of the U. S. Geological Survey, James M. Hill describes some mining districts in eastern Nevada, the accompanying map showing their situation. This publication covers 214 pages. Striking features of the region are the arrangement of the mountain ridges along northward-trending axes and the wide, flat, barren valleys between them. Eastern Nevada is somewhat better watered than the western and southern parts, and along the east base of the higher ranges are many cattle and hay ranches. Sedimentary rocks have been faulted along a series of north-trending breaks of great magnitude. The sedimentaries are in many places intruded by stocks and dikes of igneous rock, mostly approximately quartz-monzonites or granite-porphyrines in their mineral composition. Generally, the ore deposits are localized about the

centres of intrusion. Nearly all the ore deposits occur in sedimentary rocks, or in granular igneous rocks that have intruded them. The more important deposits can be divided into replacement deposits, contact-metamorphic deposits, and veins. Minerals in the ores total 41. The paper details deposits and

PART OF NEVADA, SHOWING DISTRICTS DESCRIBED.

mines in the Gold Butte district of Clark county, those in Elko, Lander, and Lincoln counties, the Bristol district of Lincoln county, some areas in Nye county, also in White Pine county.

NEW MEXICO

(Special Correspondence.)—A committee of Arizona farmers has recently visited the mills to report progress on tailing-disposal systems being arranged. It is understood that they approved of the precautions the companies are taking at no little expense to avoid running mill residue into streams. The Socorro company is storing its tailing on its own property, while the Mogollon Mines Co. is building a 5-mile flume to convey the waste to a suitable site.

The annual consumption of sawed timber in this district is 500,000 board feet, also about 40,000 lineal feet of round timber underground. Most of this has been furnished by one saw-mill on Willow mountain, now operated by Kelly & Hunter. A plant on Mineral creek was recently completed, with a board-flume 7 miles in length to convey the lumber to the divide just above Mogollon, whence the company has an easy descent for most of its timber. The water, after leaving the flume, will be piped to the base of the mountain, and it is expected to thus develop 250 h.p., sale of which has already been contracted. It is hoped to have the power-plant in commission in the spring.

Two other available power-sites are being considered, either one of which is susceptible to development on a scale sufficiently large to meet the growing consumption. Cheaper

power has long been recognized as the prime factor in arriving at a solution of lower cost of operation, and the long life of the mines warrants a strong appeal to capital for the installation.

September has been another excellent month for local operators. The Socorro Mining & Milling Co.'s properties produced 3300 lb. of gold and silver bullion and the Mogollon Mines Co., operating the Last Chance mine, shipped 2700 lb. for the same period, a total of 3 tons of precious metal in 30 days. In addition, each company shipped to the smelter at El Paso high-grade concentrate in value about equal to the bullion product, the latter going direct to mint.

The development companies also met with encouragement, particularly the Oaks company in the continued improvement of the orebody recently opened on the Queen vein of the Clifton, from which regular shipments were maintained to custom mill by burro. Another young mine, the Eureka, continues to sack high-grade ore for shipment to smelter. Results at a number of claims by prospector-owners were also good.

E. L. Perkins, superintendent of the Mogollon Mines Co., is conducting a series of flotation experiments on local ores; results so far justify the belief that a greatly simplified treatment with a substantial reduction in costs may be evolved. The Mogollon district has a recorded production of upwards of \$15,000,000, largely from an average grade of \$12 ore. This activity has extended over a period of many years, and with comparatively high costs, necessitating more or less selective mining methods. The camp has an immense tonnage of lower-grade ores in reserve. With the reduced costs of operation that will follow hydro-electric installations and the eventual adaptation of oil flotation treatment, these ores should yield as much profit as the higher grades have in the past.

Mogollon, October 3.

OKLAHOMA

CENTURY. The Montreal Mining Co. is to erect a 200-ton mill to supplement the hand-jigs at work. This is a rich mine, controlled by Canadians, and its first 100 tons of ore yielded a product containing 75% zinc-blende, by hand-jigging.

UTAH

ALTA. No. 6 diamond-drill hole in the Old Emma has cut the lead-silver orebody 25 ft. north-east of No. 5 hole. The ore is in brecciated limestone. Preparations are under way to open the shoots discovered.

BENSHAW. To extend the Montana Bingham Consolidated adit 900 ft. the Utah Karns Tunneling Machine Co. is to use the Karns machine, already at work there. According to J. P. Karns the apparatus will advance 15 ft. daily, drilling one shift and clearing away waste on two lifts. The rock at the present face, 1000 ft. in, is a quartzite. The adit is 7 by 7 ft. in the clear. The Karns machine drills a hole 12 in. diam. to a depth of 15 ft., and ordinary machine-drill are employed to drill eight additional holes to the same depth, three across the top of the face above the large hole, one on each side of it and three at the bottom of the breast. To break the ground the ordinary machine-drill holes are loaded with powder. The holes are then cut and lighted so that the small hole immediately above the large hole drilled by the Karns machine is blasted first and the others afterwards. No powder is placed in the large hole. It has taken nine years of work to perfect the present machine which is only one of a number that have been built. It is driven by a 54 in. piston from a 60 in. Rand air-drill, has an 8 in. stroke, and makes 100 strokes of 10 in. per minute under a pressure of 100 lb. The rate of the drill is built in such a manner that the principle of the ton cutting, in or out of the hole. In reality the lift is the rock only. The rate of the drill consists of a 6 in. cutting circle with two runners that keep the hole open and then the 10 in. diameter of the cutting face. The drill travels between 2 and 3 in. per minute.

PARK CITY. The Big Four Exploration Co., treating 750 tons of tailing daily, is recovering a carload of lead-iron and zinc concentrates from this.

The Judge Smelting & Mining Co. hopes to have its new reduction plant complete early in January. The main buildings are roofed ready for machinery.

SALT LAKE CITY. The Utah Copper Co. has filed an application with the State Engineer for permission to construct a canal 7 miles long to connect its mills with the canal that carries waste water from the Jordan river. A pumping station will also be erected. According to D. C. Jackling the company is earning \$1,000,000 per week, including dividends from the Nevada Consolidated. The present output is at the rate of 210,000,000 lb. of copper per annum.

TINTIC. The district's output in September was 37,500 tons of ore and concentrate valued at \$930,000. The Dragon shipped 8000 tons; Chief Con., 6000; Iron Blossom, 4200; Centennial, 3700; Grand Central, 2700; Eagle & Blue Bell, 1300; Mammoth, 2300; and Gemini, 2400 tons.

The last 10 carloads of ore from 1100 ft. depth in the Tintic Standard averaged \$1744 each, or \$35 per ton. The shoot is considered a remarkable one.

In 1915 Utah mines paid \$10,025,000 in dividends; in the current year, for 9 months, the total was \$16,909,405, as under:

	Per share	Amount in 1916	Total to date
Cardiff	\$0.50	\$250,000	\$375,000
Centennial Eureka	1.00	100,000	4,000,000
Chief Con.	0.15	132,000	282,000
Eagle & Blue Bell	0.05	45,000	492,000
Eureka Hill	1.00	10,000	2,000,000
Gemini	10.00	50,000	2,405,000
Horn Silver	0.05	10,000	5,652,000
Iron Blossom	0.25	250,000	2,750,000

Utah Metal	0.50	342,620	1,242,000
Total		\$16,909,405	\$96,716,145

CANADA

BRITISH COLUMBIA

The monthly pay-roll of the Consolidated Mining & Smelting Co. of Canada is approximately \$300,000, according to A. B. Mackenzie, secretary of the Associated Boards of Trade of Eastern British Columbia, who was recently at Spokane. The pay-roll of the smelter at Trail is \$167,000 per month, and \$90,000 is paid to the employees at the company's mines at Rossland, the War Eagle, Centre Star, and Le Roi, the remainder distributed among the workmen in other properties in British Columbia and northern Washington. Although working only six days a week, the Rossland mines are shipping over 25,000 tons of ore per month to the Trail smelter. Sunday closing of the property has become an established custom in the district and is the result of the miners having become permanent residents instead of migratory laborers.

Owing to a shortage of labor at Fernie and Coleman there are no coke ovens and the British Columbia Copper Co. cannot blast in another blast furnace. Up to September the Greenwood mine produced 3,155,578 lb. copper, 8555 oz. gold, and 33,000 lb. silver.

ONTARIO

CORALT. The Royal Commission appointed to investigate labor conditions here has made its report, consisting of one by the majority, E. Coatsworth and E. T. Corkhill; and one by the minority, Joseph Gibbons, for the employees. There were 79 witnesses examined on behalf of employees, and 8 witnesses for the mining companies. There were only two grievances, namely, (1) a demand for more wages, and (2) that employers recognize and confer with a committee appointed by the men. Otherwise the men were satisfied with conditions. In March of this year the Union commenced to talk of higher wages, and in May an increase of 25c. was given to 2800 men, also a bonus of 25c. daily when silver was 70c. or over per ounce. The men wanted all employees to be paid the increase of 25c. It was claimed that the cost of living had advanced 20 to 30%, but the companies admitted only 10%. Owing to the rise in cost of supplies the managers contended that a rise in wages was not justified. The reason why the managers would not confer with the Union committee was because they thought that the Western Federation of Miners was behind the men. The Commission considered that as the committee consisted only of local men it would have been better had the managers met the men. Reviewing all the evidence, the majority on the Commission cannot recommend an increase in wages at present. They realize what the managers have already done, and suggest that the bonus of 25c. be based on silver at 65c. per oz. instead of 70c. The minority on the Commission considers that all employees should have received an increase of 50c. per day; also that as far as the bonus was concerned wages should not be dependent on the fluctuating price of any product, especially when that product has no bearing on the cost of living.

During the year ended August 31, 1916, the Kerr Lake Mining Co. produced 2,433,793 oz. of silver at a cost of 25.25c. per oz. The profit was \$813,702, against \$550,775 in 1915, and dividends paid amounted to \$672,000. The surplus was \$141,072, compared with a deficit of \$69,225. Development covered 4056 ft. Ore reserves contain 3,827,080 oz. of silver, a decrease of 345,320 oz.

POPCINE. At the Dome Lake mine the shaft is down 456 ft. with sinking in progress to 500 ft. A stope above 300 ft. is from 10 to 15 ft. wide, averaging \$30 per ton. The new 200-ton mill is expected to be in operation by October 15.

MEXICO

Men representing the more important mining interests of Mexico are at Atlantic City to appear before the American-Mexican Commission in support of the contention that conditions in Mexico are such as to make practically impossible the resumption of mining operations. The mining committee represented 50 companies, and was composed of influential men. In the first half of 1912 Mexico yielded 33,000,000 oz. silver, 243,000 oz. gold, 74,000 tons copper, 46,000 tons zinc, and 48,000 tons lead. In the first half of 1916 the yield was 6,000,000 oz. silver, 38,000 oz. gold, 23,000 tons copper, 11,000 tons zinc, and 2000 tons of lead. Export taxes on the precious metals are four times heavier than in 1912, while the base metals now have a heavy tax, against none formerly. Forefeitures of property have been forced.

CUSHICUBACIC. Villa men have secured possession of valuable American mining property here, including the San Juan, Cusi-Mexicana, and Cusi Consolidated.

PACHUCA. The United States Smelting, Refining & Mining Co. reports as follows: Earnings for eight months (August partly estimated) after providing for all interest charges on notes, and making usual reserves for depreciation and exploration, are \$6,418,582. The Mexican properties have contributed less than 15% of the total earnings. Conditions in Mexico have improved. The company's American staff, which was withdrawn in June, is now returning.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

HOWARD D. SMITH is at Butte.

DUNCAN MACVICHIE was in San Francisco last week.

BEN. S. REVETT has returned to San Francisco from Colorado.

J. POWER HUTCHINS has arrived in London from Petrograd.

WALTER STRACHE has returned to New York from Greenland.

JOHN G. KIRCHEN, of Tonopah, was in San Francisco last week.

D'ARCY WEATHERBE has gone to Canada, returning from Russia.

THOS. B. STEARNS, of Denver, was in San Francisco last Monday.

RICHARD A. PARKER has returned to Denver from Ludlow, California.

BLANEY STEVENS is at New York; he expects to return to Mexico shortly.

S. E. BRETHERTON is in Colorado; he expects to return to San Francisco about October 24.

MORTON WEBER has been examining the American Girl group of mines at Ogilby, California.

H. C. BELLINGER is in Chile as assistant consulting engineer with the Chile Exploration Co., Chuquicamata.

ARTHUR W. JENKS has been appointed smelter manager for the Burma Mines Corporation at Nantun in Burma.

GEORGE H. UTTER, mine-owner in the Steeple Rock district, Grant county, New Mexico, is visiting in California.

ARTHUR B. FOOTE underwent the operation for appendicitis a few days ago at Grass Valley. He is convalescing satisfactorily.

F. R. VAN CAMPEN, who resigned last spring from the management of the Latouche copper mine, in Alaska, is in San Francisco.

VERNON F. MARSTERS is returning to the United States from San Juanito, Honduras, for a few months' vacation at Rushville, Indiana.

H. J. STANDER, flotation engineer for the Yaryan Resin & Turpentine Co., is at Salt Lake City, on his return from Alaska and British Columbia.

MAX J. WELCH has returned to Los Angeles from Peru, where he has superintended the construction of an experimental concentrator for the Cerro de Pasco company.

JAY P. GRAVES of Spokane, identified with the management of the Granby Consolidated company since its inception, has retired from the directorate. HENRY BRUBEK of New York succeeds him.

BURT B. BREWSTER, for two years Alaskan manager for the Sullivan Machinery Co., has been transferred to Salt Lake City, succeeding H. E. MOON. Mr. Brewster will be succeeded in Alaska by WALTER F. O'BRIEN.

JAMES L. BRUCE, general manager of the Butte & Superior Mining Co., is inspecting mines and smelters of the American Zinc, Lead & Smelting Co., in Tennessee, Missouri, Wisconsin, and Illinois, in connection with the proposed merger of these companies.

Obituary

A. C. HALL, for 16 years with the Guggenheims, died last month at Caldera, Chile.

J. J. BRISTOL died at Reno, Nevada, on August 30, of miner's phthisis contracted during underground work at several large mines of the Rand. Mr. Bristol was a graduate of the University of Nevada, and since 1900 had been in the Transvaal, on the Gold Coast of Africa, and in Alaska.

THE METAL MARKET

METAL PRICES

San Francisco, October 10.

Antimony, cents per pound	9.50
Electrolytic copper, cents per pound	29.25
Pig lead, cents per pound	7.25-8.50
Platinum: soft and hard metal, per ounce	\$90-95
Quicksilver, per flask of 75 lb.	78
Spelter, cents per pound	12
Tin, cents per pound	42
Zinc dust, cents per pound	50

ORE PRICES

San Francisco, October 10.

Chrome, 40% and over, for b. cars California, per ton	13.00-16.00
Magnetite, crude, per ton	8.00
Manganese, 50% (under 35% metal not desired)	11.00 and up
Tungsten, 60% WO ₃ per unit	17.00

The Renfrew mill in northern Ontario is paying as follows for molybdenum ore:

Per cent of MoS ₃	Price per unit
2 to 3	\$13.00
3 to 5	14.00
5 to 10	16.00
10 to 15	17.00
15 to 20	18.00
80, per pound	1.00

Penalties are imposed for bismuth and copper.
A 10% increase on tungsten has been announced at Boulder, Colorado, affecting ore containing from 2 to 10% WO₃.

New York, October 1

Antimony. For 50% ore, immediate delivery, \$1.10 has been paid in the past week.

Molybdenite. It is reported that ferro-alloy makers are using more of this mineral, with the result that inquiries are becoming more numerous. Therefore, there were only one or two buyers. Sales have been made recently at prices ranging from \$1.50 to \$1.75 per lb. of MoS₃ contained.

Tungsten. Several hundred tons of concentrates have been purchased in the past week for 1917 delivery, at about \$17 per unit ton on a profit. In addition, at least 500 tons of ferro-tungsten has been sold for foreign delivery, principally to England. For the bulk of this \$1.60, New York, per pound of contained tungsten was paid, although 20 tons brought \$2.75. It is interesting to note that Great Britain purchased one lot from a company whose name appears on the supplementary blacklist. This may be due to the fact that the British authorities have blacklisted most of the producers and dealers in tungsten and the ferro-alloys.

EASTERN METAL MARKET

(By wire from New York)

October 10. Copper is quieter than in the previous week and is quiet and steady, spotted for order following is the following:

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date	Week ending
Sept. 12	75.00
19	75.00

Monthly averages	1914	1915	1916
Jan.	29.25	51.90	72.00

Tin in London, Oct. 12, 1916, 100.00.

Eastern Metal Market

New York, October 4.

Copper is quieter, but strong.

Zinc has advanced, although buying has been comparatively light. Its strength is based on expectations that the Allies will enter the market for large quantities.

Lead is steady, but quieter.

A big movement in tin is looked for, and already there are indications that the tin-plate mills are considering their requirements.

Antimony is dull and weaker.

Aluminum is strong.

Tungsten ore has been active.

For molybdenite there is a widening market.

A purchase of 200,000 tons of Brazilian manganese ore, is reported. The ore is for delivery over 1917, and contains about 48%. The terms of the sale specify delivery at Rio de Janeiro, the buyer to furnish vessels from that point. At the present freight rate of \$12 per ton, the cost would approximate 75c. per unit f.o.b. cars, Baltimore. Figuring current freight-rates, the transaction would represent an investment of \$6,500,000. It indicates that large interests do not expect the War to end next year, or that any relief is to be expected in the matter of forcing the Dardenelles, or obtaining manganese ore in large quantities from India next year.

The most pleasing feature of the iron and steel markets this past week is the greater activity in pig iron of all grades. With the activity came price advances. So far, foundry iron in particular has lagged far behind other products. Constantly increasing export demand is in large part responsible for the greater activity, although domestic smelters are showing more confidence also. Standard low-phosphorous pig iron, much used for wire, projectiles, and the finer grades of steel, is quoted at \$36 to \$37 per ton, delivered, and \$40 is predicted in the near future. Basic iron, for open-hearth consumption, has also been in heavy demand. The production of pig iron in September was 3,202,366 tons or 106,745 tons per day, against 3,203,713 tons in August or 103,346 tons per day. October opens with 328 furnaces in blast.

The railroads are placing orders for cars, the demand for plates is greater than ever, and a steel famine is freely predicted. August exports of iron and steel totaled 598,192 tons against the previous high record of 540,000 tons in May. There is every indication that tin-plate prices, which have not been fixed for 1917, will be higher.

The scarcity of labor is a common cry.

Steel plates are quoted at 4c., Pittsburg, structural shapes at 2.75c., and bars at 2.75c., premiums being exacted wherever prompt deliveries are wanted.

COPPER

As might well be expected comparative quiet has followed the recent big buying, but with first-hands in an unprecedented position as to the next three-quarters of a year, their quotations are firmly held. For electrolytic, October delivery, up to 29c. is asked, for November 28.50c., for December 28c., for January 27.50c., and for first quarter 27.25c. Lake producers are reported to be sold-up for the remainder of the year. A re-sale lot offered at 29.50c. failed to induce any action this week. For January delivery the Lake producers are asking 27.50c., and for first quarter 27.25c. To a great extent, sales are today a matter of extended negotiations. Companies who have been asked to quote have replied that they had nothing to sell for certain positions, but when they have been approached with a specific proposition they found the metal and sales have resulted. With second-hands prices are a little easier, sales of electrolytic for near-by delivery

having been reported at 28.75c. The electrolytic quotation at London yesterday was £140 against £138 a week previous. The September exports reached the excellent total of 29,803 tons. Stocks in Great Britain and France on October 1 amounted to 5796 tons against 7118 tons on September 15. Including the copper afloat from Chile and Australia, the total European supply on October 1 totaled 10,371 tons, against 11,668 tons two weeks previous. The brass and copper mills continue as busy as ever and are carefully picking what they want from new business offered them.

ZINC

Only spasmodic buying, moderate in the aggregate, has taken place in the past week, but prices have nevertheless advanced, with the result that spot is held around 9.70c., New York, and 9.50c., St. Louis. Last quarter is held at 9.25 to 9.37½c., St. Louis, and first quarter at 9 to 9.12½c., St. Louis. The producers are strong in their belief that the Allies will sooner or later come into the market for large quantities as a concomitant of their recent large purchase of copper. The London market is strong at £52 per ton for spot, the quotation of a week ago. Exports are extremely large, those of September amounting to 14,309 tons, while in the first three days of this month they totaled 1721 tons, 1231 tons of which was shipped to Archangel, Russia. Sheet zinc is unchanged at 15c., f.o.b. mill, carload lots, 8% off for cash.

LEAD

The leading interest continued to quote 7c., New York, and 6.92½c. St. Louis. The New York quotations of the independent producers and sellers have varied from 7 to 7.12½c. Yesterday they asked 7.05c., New York. Some of them are so well sold-up that they are practically out of the market on near-by deliveries. A large amount of lead has been sold in recent days, and it is therefore natural that the market should become quieter. Bullish talk is heard as to the future, although conservative members of the trade believe that a firm steady market is to be expected rather than one of sky-rocket tendencies. The fact is that consumers have pretty well covered their requirements for the remainder of the year. At the same time it is to be recognized that consumption and production are running about even, and if a good foreign demand should develop it will send prices upward. Exports continue on an excellent scale, those of September amounting to 8857 tons. The London quotation for spot yesterday was 5s. higher than a week ago, at £31 15s.

TIN

The feeling is widespread that a good movement in tin is impending. It is believed that buying on September 29 was a forerunner of the expected business, as on that day large tin-plate makers took about 400 tons. More interest is being shown in future positions, and prices are advancing. Spot Straits was quoted yesterday at 39.25c., New York. The September statistics show that deliveries into consumption in that month totaled 5025 tons, of which 675 tons came via Pacific ports. Deliveries since January total 44,413 tons, against 36,905 tons in the same period of 1915. In stock and landing on October 1, was 4769 tons. The quantity afloat, on the 3rd, was 2145 tons.

ANTIMONY

No interest is shown, and prices are sagging. Oriental grades can be had from dealers at 10.25 to 10.50c., duty paid.

ALUMINUM

The market is firm at 62 to 63c. per lb. for No. 1 virgin metal, 98 to 99% pure.

Book Reviews

METHODS IN METALLURGICAL ANALYSIS. By Charles H. White. P. 556. Ill., index. D. Van Nostrand Co., New York, 1915. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.50.

Many books treat of the subject of assaying, and myriads deal with the varied phases of metallurgical analysis, but the one handy volume that presents the best methods of the chemical analysis of all mining and metallurgical products is the above, by one, who for many years has taught that subject in Harvard University. The book is compact and can be slipped into the pocket. It has a substantial binding. The first chapters deal with laboratory equipment and manipulation—most useful to the beginner or for the engineer who is forced to 'brush-up.' The scope of the book may best be realized by a glance at the main headings: Equipment of the laboratory; Sampling; Operation of analysis; Analyses of iron ores, iron and steel, ores of copper and the minor metals, slag, mattes, bullion, alloys; Fire-assaying; Analyses of the cyanide-mill; Analyses of fluxes, fuels, clay, boiler-water; The determination of rare metals; and Tables. The book is not only comprehensive, but it is critical. Every method of analysis described has stood the test of the mill and the smelter. It tells what happens and why it happens, and all pit-falls are plainly marked.—Walter S. Weeks.

EXAMPLES IN ALTERNATING CURRENTS. Vol. I. By F. E. Austin. Second Edition. P. 225. Ill., index. F. E. Austin. Hanover, N. H. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.40.

This book is a reprint of the first edition, to which has been added considerable new material in the form of cuts and subject matter. The aim of the author has been to bring together the theory and practice in alternating currents by presenting problems and showing how they are solved by the application of mathematical formulae. The first 10 pages are devoted to definitions of fundamental units, signs employed in the formulae, trigonometrical functions, and calculus. Then follow the problems; the statement, the data, formulae which apply, and lastly the solution are presented in such a manner as to easily follow each step. The appendix contains a number of tables giving the values of variable quantities used in electrical engineering practice, so arranged as to include a wide range of values and to render evaluation convenient and rapid. To the student the book is valuable in that it trains and guides him in understanding the solution of electrical problems, while to the engineer its chief value is in the carefully tabulated arrangement of mathematical and electrical data.

CENTRIFUGAL PUMPS AND SUCTION DREDGES. By E. W. Sargeant. P. 188. Ill., plans, index. Charles Griffin & Co., London, 1916; J. B. Lippincott Co., Philadelphia. For sale by the MINING AND SCIENTIFIC PRESS. Price \$2.25.

Centrifugal pumps—belt motor, oil engine, or turbine driven—from 1 to 54-in. discharge, are now used in far greater numbers on dredges, for unwatering mines, elevating coal and fine pulp in mills, fire purposes, sewage, and irrigation. Their popularity increases as they are better understood and as improvements in efficiency are made. Although the book deals with English practice the information is useful to Americans, as the former have made good centrifugal pumps for many years. In the United States the metallurgist and the civil engineer have studied the centrifugal considerably, resulting in long-wearing liners and great capacity, especially for high lifts. The multi-stage pump is a great success, the subject being covered in two chapters. Design of the pump and casing

are all-important, this being thoroughly discussed, including pattern making, molding, and machining. For priming a centrifugal several methods are given, also testing its capacity and efficiency. Pipe arrangements and valves are considered. As the rotary air-pump is closely related to the centrifugal it is briefly described. These are used at mines for various purposes. While the pump type of gold dredge is not worked much in America, it is a success in Australia, lifting large quantities of coarse gravel with ease up to 15-in. suction; but in harbors and rivers the suction dredge is operated everywhere, using centrifugal pumps. Here the engineer will find practical notes. Calculations and plans complete a work on an important machine.

PRACTICAL HYDRAULICS. By James Park. P. 284. Ill., charts, plans, index. Charles Griffin & Co., London, 1916; J. B. Lippincott Co., Philadelphia. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.

The author of this work, who is professor in the University of Otago, at Dunedin, New Zealand, writes on many subjects, including assaying, cyaniding, surveying, and geology. In the South Island of New Zealand the author has many opportunities to study hydraulics, this being a region containing rivers, large ditches, hydraulic mining, and dredging. The volume is termed a text-book for use in mining schools, technical colleges, and for hydraulic engineers. A good deal of the data has been drawn from American sources, and this, together with Australasian and foreign practice, makes a good mixture. Eight chapters cover principles, definition of terms, and the flow of water through orifices, open channels, over weirs, and in rivers; also friction in and discharge of pipes. Construction of dams, ditches, flumes, and pipes is of great importance, as these are subjected to varying pressures, sometimes suddenly abnormal, so examples of well-designed structures are described and shown by working plans. Costs are included. The last chapter covers the subject of water-power and water prime-movers. These include the latest type Pelton wheel and turbines. While American engineers are well versed in hydraulics, they should find something of value in this new book.

LABOR TROUBLES harass the metal-working trades in many parts of the country. Not only is there an inadequate supply, but in some cities housing facilities are not sufficient, and the high rents that are asked are driving mechanics to other places, this being notably true in Detroit. Pittsburg is beginning to suffer from a shortage of freight-cars, which already has cut down shipments. The export buying of steel continues on an enormous scale and premium prices are paid without murmur on foreign account. Manufacturers of steel plates, particularly ship-plates, are submerged with orders. Most of the mills will not consider under 4c., Pittsburg base, for any delivery of tank-plates.

BY MEANS of a process recently invented by Phillip McKenna of the Vanadium Alloys Steel Co., which is operating at Boulder, Colorado, under the name of the Vasco Mining & Milling Co. it is producing ferro-tungsten which the company claims has never as yet been equalled in the high percentage of tungsten content, and low percentage of impurities. The Vanadium Alloys company is now guaranteeing its ferro-tungsten to contain from 70 to 80% tungsten and not over 0.5% carbon or 0.05% silicon. The Vasco company has already shipped 34 tons of 50% concentrate to the Vanadium Alloys at Pittsburg, Penn. (Reams)

A COUNCIL REPORT from Valparaiso, dated September 10, 1916, that is set to newspaper reports the Chile Exploration Co. has sold the copper mining properties of the Compañía Minera de Chuquibambilla for the sum of 7,100,000 Chilean pesos, equivalent to 9 pence exchange to about \$1,280,000 United States currency.

EDITORIAL

T. A. RICKARD, Editor

SCIENTIFIC evidence that the addition of copper to steel and iron increases their resistance to corrosion is a fact that may prove important to the mining industry. We publish a note on the subject.

CALUMET & Hecla is said to be experimenting successfully with flotation, to supplement the Benedict leaching process. No mill-man can afford to neglect the possibilities of flotation. Every mill ought to contain a small machine for making flotation tests.

LABOR is scarce everywhere, but the shortage would disappear if every able-bodied idle man would go to work. While thousands dispute over the length of the working-day, other thousands decide for themselves that no work is best. In an organized community, the shirker should find it as unpleasant during peace as during war.

WHETHER a U-boat or a peace rumor does more to put the soft pedal on a bull campaign on Wall Street, we do not know; but the incidence of either should remind the sagacious man that we live in the midst of uncontrollable factors likely to upset the calculations of the most far-seeing. Many seismic events will happen before we make a return to normal times.

DEMONETIZATION of gold by Great Britain, in the event of the War lasting for another year, is being discussed. The sinister suggestion has grown from a remark in *The Statist* that Great Britain may be compelled to suspend specie payment if her financial resources are stretched too far. The suggestion is one that we do not take seriously, but those at a loss for a topic of conversation may offer guesses as to the world-wide consequences of such a step.

WE note that the Minerals Separation company has insisted successfully on the Miami Copper Company filing a bond for \$250,000 and making monthly reports of the particulars of its flotation operations and the value of the concentrate recovered. This accounting is to be made to the Court at Wilmington, Delaware. Meanwhile the Miami company has filed its appeal to the U. S. Circuit Court of Appeals at Philadelphia. It is announced that the argument of the Hyde case in the Supreme Court of the United States will begin in a few days.

SINCE we published the 'personal' regarding Mr. E. P. Mathewson's resignation and new appointment, in our issue of the 7th instant, the paragraph

about his new work with the British-America Nickel Corporation has appeared in many papers, but usually with an extra 'n' after the word America. We note that the *Anaconda Standard* expresses, in feeling terms, the regret of the people of Montana at Mr. Mathewson's departure from Anaconda. We can understand that. At an early date we shall publish an interview obtained with Mr. Mathewson while he was here recently.

"HIGHEST on record" is a cheerful phrase when it refers to stocks or prices of metals, but it is chilling when it describes the cost of living. According to *The Annalist* index-number of the average price of a number of representative commodities, the cost of living is now 186.84 as compared with 139.72 a year ago. This is a rise of 33.7%. Since the War began the cost of food has risen 59% in England and 107% in Germany. In 20 years the cost of living in the United States has doubled. Perhaps a more significant fact is the doubling of the price of the machine-made pie that has replaced the wholesome comestible of the New England housewife. Peace hath her perils no less than War.

THE success or failure of any mining method depends upon the recognition of its advantages and limitations, and applying it where the conditions are suitable. No system is so elastic as to be applicable in all cases. The first step is to choose the system fitted to the given set of conditions, for on this choice may rest the fate of the entire undertaking. On another page we publish an article, by Mr. E. G. Deane, describing the block method of top-slicing as used by the Miami Copper Company. Like the sub-level caving-system, described in our issue of October 7, it is adapted to large orebodies of uniform grade. It has one advantage not possessed by the sub-level caving-system in that it permits removal and storage of the waste by sorting in the stopes. Almost complete extraction is possible, as the waste of the cap does not mix with the ore. A small amount of preparatory work is necessary and is productive, being done in the ore. When properly carried out there is practically no danger of falls, the timber usually giving ample warning when about to take excessive weight. It is possible to shoot-down a portion of the stope and so relieve the pressure without the necessity of abandoning it. The method is wasteful of timber, as nearly all of it is lost, but since its use is temporary a cheap inferior grade can be utilized. There is considerable handling of timber, which must be hoisted to the stopes from the haulage-levels. Good ventilation is essential, otherwise the temperature

due to the decaying timber in the mat overhead reduces the efficiency of the miners and also increases the danger of fires. Unless the raises are near together in the stopes there is much handling of the ore. A chute interval of 50-ft. centres seems to be too large, necessitating a great deal of work by the shovelers in loading and wheeling the ore to the chutes. The complete extraction of the ore possible by this method equalizes the higher cost due to loss of timber and the increased amount of handling that is necessary. A production of 10 tons per man-shift at an estimated cost of only 88 cents per ton speaks for itself.

MEXICAN affairs are discussed by our Special Correspondent under the heading of 'Review of Mining.' Those interested in the subject will find both information and comment of a timely kind. An abstract of recent decrees issued by the Carranzista government will be useful for reference. The tripling of the export tax on metals is noteworthy. The new taxation of mineral land is not unreasonable. On the other hand, the renouncement of diplomatic protection is ominous; the decree is unnecessary if Carranza intends to treat the foreigner fairly. Our correspondent discusses this point lucidly. 'Mexico for the Mexicans' is a slogan to which none of us could object if our nationals had not been invited by successive Mexican governments to give a hand in developing the industrial resources of the country and if our nationals in so doing had not been guaranteed protection. That is a point entirely disregarded both at Mexico City and at Washington as Mrs. O'Shaughnessy spells the seat of administration. Among his other pronouncements, Señor Carranza has interdicted bullfighting. This is commendable, but the slaughter of bulls might be ignored just now in face of the assassination of human beings to which the warring factions are committed. Despite the unsettled political conditions the American managers of mines are returning to Mexico with a view to resuming operations. The optimism of the mining engineer is unconquerable. On the whole, the news concerning conditions in Mexico has been encouraging recently, so that resumption of mining is recorded at many points, notably Pachuca, El Oro, Guadalajara, and along the West Coast. Meanwhile the Joint Commission continues in session at Atlantic City and is likely to remain in active conversation until after the presidential election.

DISCUSSION this week is enriched by letters from widely separated sources. Mr. W. E. Thorne, a Californian engineer, writes from Siberia to correct sundry details in a recent description of alluvial mining methods on the Lena goldfield. Mr. L. J. Hohl draws the pen in defence of Mr. Shockley. When Mr. Hohl wrote his letter he was quite unaware of the action being taken by the local section of the Institute, although subsequently he attended the meeting at which that action was ratified. His letter is amusing in showing how ineffective was the censoring of Mr. Shockley's paper, for

the statements to which objection was taken are to be found in figures or by inference in the paper as it now appears in the proceedings of the Engineering Congress. The quotation of George F. Baer's celebrated saying was bound to be made by somebody during the discussion of this episode and we are glad that Mr. Hohl should have taken pains to quote it accurately. The letter from a prospector will commend itself as the record of a bit of personal experience. Major Karri Davies will be known to any reader familiar with the history of South Africa. We welcome his comment on our recent editorial and acknowledge the slip made in our statement of the ratio of productive to unproductive ground in the Far East Rand. The suggestion for a method of adjusting the deduction of the Government's share of profit without penalizing efficiency is well worthy of consideration. Our friend Mr. Thomas T. Read has settled the spelling of McDougall, as applied to the furnace of that name. 'McDougall' it shall be henceforth. The letter from Mr. George E. Collins supports the Everson tradition and includes an interesting suggestion. The real point is that Everson, whether the lady or her husband does not matter, obtained a patent for a process that was never worked successfully and was, we believe, unworkable. The Ethore brothers devised a process that was used in a mill and served as the beginning for a revolution in metallurgy.

A Matter of Principle

On another page we publish a protest made by Mr. William H. Shockley against the censoring of a paper presented by him to the International Engineering Congress last year. He protests, not so much against the censoring of his paper by the publication committee of the Congress, but against the interference of the board of directors of the American Institute of Mining Engineers, acting upon the peremptory demand of the Anthracite Section of the Institute. We refer the readers to the facts as stated by Mr. Shockley. His statement is plain and reasonable. For those that do not know him personally we may say that he is a mining engineer of wide experience and ripe knowledge; he has shown good temper and no small amount of courtesy throughout the episode; in every respect he is a worthy representative of the profession and entitled to the consideration that any one of us has the right to demand. In the first instance, he was requested to prepare a paper on the economics and sociology of mining; the request was made by Mr. H. Foster Bain, at that time a member of the management committee of the Congress. Mr. H. C. Hoover had been expected to write a paper on this particular subject, and when he was unable to do so, owing to his great work in Belgium, the task was delegated to Mr. Shockley, who, in agreeing to write the paper informed Mr. Bain how he expected to treat the subject. Mr. Bain knew Mr. Shockley well and was aware of his radical views. Nevertheless Mr. Bain officially urged

Mr. Shockley to prepare the paper. He did so. The paper was passed by the editors and accepted by the publication committee of the Congress; it was printed and circulated by the Congress. At the meeting of the Congress in September 1915, Mr. Shockley read an abstract of his paper and on that occasion one or two of the anthracite engineers objected to some of his statements. The discussion was cut short by lack of time. Subsequently Messrs. Edwin Ludlow and R. V. Norris, of the Anthracite Section at Wilkes-Barre, Pennsylvania, called upon Mr. Shockley to withdraw some of the statements in his paper. He demurred to doing so, suggesting that they contribute to the discussion and present their own view of the question in dispute. After some correspondence between the parties to the controversy, Mr. Shockley made sundry changes, which did not suit the anthracite engineers. Finally on June 11 a telegram, quoted in full in Mr. Shockley's protest, was addressed to the Chairman of the Congress at San Francisco, insisting that all reference to the anthracite region "be expunged from the paper by order of the directors of the Anthracite Section of the American Institute of Mining Engineers." When this imperious dispatch was received by the Secretary of the Congress he called a meeting of representative mining engineers and officials of the Congress. Those present at the meeting resolved unanimously that the tone of the telegram was most objectionable and that the Chairman of the Congress, then at Brooklyn, be advised to publish Mr. Shockley's paper as already amended. On June 23 the directors of the American Institute of Mining Engineers voted that unless Mr. Shockley's paper was changed to meet the views of the Anthracite Section, it should not be published. A copy of this resolution was sent to the Chairman of the Engineering Congress. He, meanwhile, had ignored the expression of opinion voiced by the committee called by the Secretary on June 12 and was now inclined to waive his rights. The offices of the Congress were being maintained pending the settlement of the dispute, causing expense and worry, whereupon Mr. Shockley cut the matter short by agreeing to omit the remarks to which objection had been made by the Anthracite Section, replacing them by an explanatory note. When the facts of the case became known, the matter was brought before the San Francisco Section of the Institute, a feeling of resentment against the injustice done to Mr. Shockley was freely expressed, and on October 10 a resolution was carried unanimously stating *inter alia* that "the action of the directors of the American Institute of Mining Engineers in censoring the publication of Mr. Shockley's paper is unwarrantable." That is the story to date. It is not a pleasant one. Mr. Shockley expressed no opinion of his own concerning the conditions prevailing in the anthracite region, he said only that if the wages were so much and the cost of living so much, then it was probable that a number of heads of families were inadequately paid. He quoted figures from the U. S. Immigration Commission and from a report of the State of Pennsylvania. If the gentlemen at

Wilkes-Barre did not like it, they were at liberty to refute Mr. Shockley in the usual way, by contributing their opinions to the discussion of his paper. They had no right to demand the deletion of the paragraphs that did not please them and they were not warranted, we submit, in calling upon the directors of the Institute to take drastic action. As for the directors, their action is indefensible. By what right did they dictate to the Engineering Congress what it should or should not publish? It is true the Institute was one of the five technical societies that contributed to the underwriting of the Congress, but did that give them the privilege of editor or censor? As for the Congress management, it acted weakly and ingloriously in surrendering its responsibility to the clamor of a coterie of excellent gentlemen representing the one great natural monopoly in the United States. What a bungle they, and the others supporting them, made of their censoring is shown admirably in the letter from Mr. L. J. Hohl, appearing under 'Discussion.' Similarly in a discussion of the Panama Canal before the Congress sundry thoughtful criticisms were presented in discussion by Mr. C. E. Grunsky, a veteran engineer and member of a Government Canal Commission, and because his remarks did not suit the powers that be, he was asked to withdraw them, and on his failure to do so, the Committee of Management passed a resolution withdrawing all the discussion from publication, although it had been announced officially, in notices to the engineering profession, that "written discussions would be welcomed in any language." Some people appear to be mighty particular about the language! We do not believe in the suppression of honest criticism; we believe that suppression prevents the creation of a healthy public opinion; in the end it hurts those criticized much more than a frank ventilation of conflicting ideas. But the most objectionable feature of the episode is the action of the directors of the Institute in issuing a ukase against one of its own members and against inferences expressed by him not in the transactions of the Institute but in the proceedings of another organization. This is an interference with the liberty of the professional man and it is not to be tolerated.

The Decadence of the Rand

The mining industry of the Rand is a subject interesting to the American mining engineer for many reasons, to which a new one has been added by the possibility of American capital participating as a separate unit in the exploitation of this, the greatest goldfield in the world. Our readers are aware that an American syndicate, headed by the Messrs. Lewisohn, sent an expeditionary force of engineers to Johannesburg in the early part of this year to investigate the chance of profitable business, more particularly in that part of the goldfield called the Far East Rand. Whether anything is to come from this incursion of American enterprise we do not know, but the fact that it has been made affords an excuse for com-

menting on Rand affairs from the American point of view. We shall be frank, believing that in frankness lies the best possibility of being useful.

The business of the Rand, that is, the flotation, financing, and management of the gold mines, is in the hands of the so-called groups, financial organizations founded in the early days by individual operators of great initiative and resourcefulness. These 'big houses,' as they are also called, appear to work under a tacit agreement not to trespass upon each other's preserves; no group has wrested the control or management of mines from another group; even in the case of a fiasco like that of the East Rand Proprietary there were no signs of an attempt to take advantage of the weakness of the old directorate. It is true the Central Mining people obtained the direction of affairs in place of the Farrars, but the Central Mining had a large block of stock in the company and protected the late Sir George Farrar so as to save his face and leave him in his position of chairman. Sir Joseph Robinson has played a lone hand and cannot be included in the pact, but he also has not attempted to wrest control from any other group, nor they from him. At the time of the tenders for the Government Areas the Barnatos were not included in the general group agreement as to the Far East Rand exploitation, so that their solitary action in tendering was likewise no infraction of the general understanding to which we have referred. Such an understanding may simplify life for those in control but it is not calculated to promote the best interests of the industry. Signs are not wanting that a complacent disposition over past performances is tending to technical stagnation. The infusion of fresh blood might restore the spirit of youthfulness to an industry prematurely venerable. The personnel of the companies has lost distinction, it is composed mainly of men of local origin and training, the result of continuous promotion from the ranks, diminishing the chance of such diversified experience as is essential to any successful departure from the beaten track. The introduction of new methods, aimed to lower the cost of exploitation, would be more likely if advantage were taken of the recent knowledge obtained in low-grade copper mining in Arizona and in the large scale working of such gold deposits as those of Jumeau, where new records for low cost have been made during the last two or three years. We recognize the growth of a feeling of national solidarity or exclusiveness, according to the point of view, engendered by the War and the consequent desire to have the resources of the British empire developed by British capital, but an American may be permitted to smile at the attitude of the naturalized German Jew element, which is more British than the British in the expressed wish to exclude aliens. The Germans in the Transvaal need to make no apology, they have played an honorable part in the development of the Rand and their retirement during the Great Unpleasantness left the non-national German Jew to pose, as an imperialist of 21 carat purity. A number of these have been promoted to authority under the group system establishing an an-

cracy that has stifled the initiative and character essential to any great accomplishment. The big men that made the Rand—Alfred Beit, Julius Wernher, J. B. Taylor, Cecil Rhodes, George Farrar, Hermann Eckstein, and the like—have been succeeded by men who were mostly clerks in their service, without technical education or knowledge of mining outside the Rand. The groups are no longer the real owners of the mines but controllers by virtue of proxies, with the result that the share-dealing part of the business has been magnified at the expense of the exploratory and development phases of the operations. The coterie of office-holders now controlling the industry from London lacks the authority to delegate initiative to their representatives at Johannesburg, and this in turn detracts from the usefulness of the engineer and of the manager at the mine. A miasma of indirection afflicts the entire system. One result is to side-step the problem of native labor. The observant visitor agrees with the enlightened Boer that the best results are not being obtained from the Kaffir, because his capacity is restricted arbitrarily by an artificial barrier. For example, the native is not permitted to use an explosive, to serve as station or skip-tender, or to handle a winch in which men are raised and lowered. In other mining districts such tasks are performed safely by Koreans, Mexican Indians, and negroes of every shade. The white-labor union is allowed to dominate the economic conditions; the native is not permitted to advance according to the proof of his intelligence nor is he accorded full scope for the ability developed by training. The white man plays the part of an expensive supervisor. The economic waste is undeniable. Pay in proportion to efficiency would promote skill and the raising of wages would increase the wants of the native so as to prompt him to remain at work. These are observations established by experience in every part of the world where the indigenous population has been harnessed to industry. Just now there is an abundant supply of native labor on the Rand and it is being used lavishly under a diminished white supervision. In this and other matters the mines suffer from politics. Several of the leading operators are prominent in parliamentary affairs, in opposition to a violent Labor party, creating bitter antagonisms not at all good for the welfare of the South African Union. The Chamber of Mines itself is semi-political and the newspapers are under control of the groups, the general result being prejudicial to the maintenance of a healthy state of public opinion or of an atmosphere in which useful criticism can live. The Rand needs new capital, which the present groups are not competent to furnish; it needs new ideas in technology, which those bred in the locality are unlikely to conceive. By aid of one and the other it should be possible to accomplish a good deal; for instance, reduce the cost to 10 shillings per ton and thereby extend the resources of the goldfield not only by finding new ore but by widening the margin of profit to be gained from the ore already proved; in other words, give a new lease of life to the Rand.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Lena Goldfield

The Editor:

Sir—In your concentrates of April 15, 1916, the statement appears that "trommels and *kulibinas* washing-machines at the Lena gravel mine, Siberia, have been replaced by the long sluices of the Alaska type, resulting in less loss of gold and lower cost, 56 to 35 cents per cubic yard."

This is incorrect. The long sluices were tried with parallel T-rail rifles, but most of them have been discarded, because they were losing more gold than the other type of rifle. The parallel is o.k. for suitable material and capacity, but for such material as we have here they are not suitable. The gravel is subangular, with some clay, therefore the Hungarian type of rifle is better with frequent drops of a few inches in the sluice.

The reduced cost per cubic yard is from the winter-washing plants; a good part of the gravel goes direct to the sluice from the mine, and is not thrown on the winter dump to be re-handled, as was the former practice. These winter-washing plants were recommended by Leon Perret, general manager in 1913-'14, a Russian mining engineer; they were installed by R. E. Smith, an American.

A Matter of Principle

The Editor:

Sir—A few days ago I received my copy of 'Transactions of the International Engineering Congress 1915—Mining Engineering' and found on page 17 ('The Economic and Social Influence of Mining with Special Reference to the United States,' by William H. Shockley) the following foot-note by the author.

"The writing of this paper was completed in June 1915, and when presented at the meeting of the International Engineering Congress in September 1915, it contained statistics, drawn chiefly from Vol. 16 of the Immigration Commission Reports, which seemed to show that the pay of the anthracite miners in Pennsylvania was less than the amount required for physically efficient living. These statistics were claimed to be erroneous by the Anthracite Section of the American Institute of Mining Engineers, and the Section asked that they be omitted. The same request was also made by the American Institute of Mining Engineers.

"In view of the fact that since the paper was written

the wages of the anthracite miners have been materially increased and their hours of labor reduced to eight, daily, and therefore their living conditions have been improved, and, furthermore, in order to avoid controversy in the transactions of this Congress, the author has consented to omit these statistics and his remarks, indicated by asterisks on this and subsequent pages, relating to the anthracite miners' wages. This step is taken by the author in deference to the request of the Committee of Management of the Congress and without prejudice to his own views in the matter."

During the great strike in the anthracite region in 1902 George F. Baer, the head of the coal trust was quoted as stating: "The rights and interests of the laboring man will be protected and cared for, not by labor and agitation, but by the Christian men to whom God in his infinite wisdom has given control of the property interests of the country." Mr. Baer, I understand, is dead, but evidently "his soul goes marching on."

The censor however has not done very efficient work. While he has eliminated from the report the statement of average yearly earnings of the miners in Pennsylvania, he has permitted those data for the State of Indiana to remain; these show that the average annual earnings vary from \$499.61 to \$737.27, leaving the reader to infer that the wages for Pennsylvania must have been much lower. He has further permitted a statement showing the cost of living at Johnstown, Pa., to be \$780 per annum. This latter statement is on page 20 and immediately following it we find the ominous line of asterisks.

And finally on pages 42 and 43, we find the following statement:

"According to the mine operators' statement, these miners (Southern Colorado) are making the highest wages of any coal miners in the United States; the annual wages for all miners in the Victor American Fuel Co. for the year ending June 30, 1913, were \$1100.75; for the same period the miners of the Colorado Fuel & Iron Co. made \$999.36; the average being more than twice that of the anthracite miners of Pennsylvania."

Thus we surmise, that the annual wages of the anthracite miner must be considerably less than \$500 per annum, and admitting that they have been increased, it is not to be presumed that the increase has reached the sum of \$780 per annum, the cost of living.

But the point I wish to make is one of principle. Even assuming that the statistics cited by the author were wrong and misleading, the suppression of them is un-

warranted and the plea that controversy might ensue evades the issue.

Controversy is much more likely to ensue from suppressed data, which leave the door open to all kind of surmises; moreover if the figures were erroneous, as claimed, the author of the paper would certainly not have offered any objections to the publication in a footnote of the figures claimed to be correct, showing, as he has done, the source of information.

As the matter stands, Mr. Shockley's footnote reads very much like the famous recantation of Galileo and its closing paragraph recalls his "*E pur si muove.*"

[This subject is discussed in our editorial columns.—Editor.]

Prospecting

The Editor:

Sir—Under 'Prospecting,' Mr. Sharpless says he would like to read an experience or two; so I donate one. Some 15 years ago, I was 30 years old, single, worth \$5 per day around a mine, had worked as assayer, shift-boss, foreman, etc., knew ore when I saw it, and fairly honest and reliable. This I mention rather to impress the fact that there are many such. I was tired of working for wages six months or so, then a new suit of clothes and a bright red interval, and then another grind. I figured that by putting in a year or two prospecting, I would do better; so made the following offer to some business men, friends of mine:

I would contract to prospect for six months to two years; to supply my own outfit and pay all expenses; to receive one-half of any discovery and one-half wages, or \$2.50 daily; or one-fourth interest and three-fourths wages. I figured that this was perfectly fair; and if we had no luck, at least I would have a few dollars at the end of the period to turn around with. My friends turned this down cold, saying that they could get plenty of men willing to go prospecting for \$10 to \$15 a month and one-half of any find. I looked around the town and saw that they were right, there were plenty of hobos who were only too glad of a month's hand out all in a bunch. The more I studied the question, the more I was convinced that there was something wrong. I, of course, knew that my offer was perfectly fair, but I also knew that those friends of mine were good business men; so I decided to go after the question differently. I picked out a known mineralized section and camped right there for wages at \$5 per day; of a Sunday I would look around, would listen to the prospectors, spend a few dollars for assays and so on. At last I got hold of a promising looking property; no partners, whatever. Every month so much wages would go to development; and this was much more fun than looking forward to the new suit of clothes.

I got married and began to find that \$5 per day was a whole lot more money than I had ever imagined. I leased the mine, as we had struck ore, and now it is

bringing me in a little money; with the good chance of making a valuable property. I will mention that in the ordinary course of things, I became acquainted with several mining engineers and geologists, who looked over my property and gave me some valuable advice, charging me absolutely nothing. They did this purely for friendship's sake; and I am certain that any of them will do this for a prospector if his mine is not too far out of their road, and weather permitting.

Now, suppose that a man wishing to invest money prospecting, in place of looking up and grubstaking someone, should proceed in the following manner: Pick out a district which he favors; look up the engineers who have practised there; ask one of them if he has not seen some promising prospects or prospectors in that locality; or perhaps a mine too small for a large company, but still a good little mine. What will this engineer charge for this valuable information or will he answer at all?

I venture the guess that he will give a rough outline of the camp freely, charging nothing; an exchange of cards perhaps; for the rest—the human equation.

PROSPECTOR.

Nacozari, September 21.

Gold Mining in South Africa

The Editor:

Sir—When a mining district has produced over two and a quarter billions worth of gold, paid enormous dividends, and is today producing over fifteen million dollars per month, it is surely worthy of careful consideration on the part of Americans. More especially when it is known that this amount has been produced from 40 square miles of conglomerate and that there is still five times as much of the same formation of gold-bearing rock to be explored and developed.

Having lived in South Africa for twenty years, and still owning interests there, you will understand the pleasure your editorial on 'The Far East Rand' (in your issue of October 7) has given me, and no doubt many others. A long acquaintance with the Government Mining Engineer enables me to cordially endorse your remark that "he is thoroughly capable and fair-minded." He is also the last man to place an embargo on efficiency.

Mr. Kotze in his recent report on the Far East Rand is aiming to make a provision whereby any company working this Government-owned ground will receive the full benefit they are entitled to by their skill and ability in reducing the working and developing costs of normal times.

The only way which suggests itself to me for this being done is for Mr. Kotze to arrive at a standard working cost per ton milled and a standard development cost based on today's, or normal time, prices. With the data he has at his disposal, together with the consistent conditions of mining he has to deal with in this case, this should not be so difficult. When these figures are fixed, it should not be hard as far as working and develop-

ment costs are concerned) to determine the Government's proportion of profit, based on these standard costs, although it might involve a tonnage calculation, which should not offer an insurmountable difficulty. By this method, the Government would get the advantage of the full value of the ore and the company the full advantage of any reduction in working costs below today's, or normal times, which they would be entitled to from any improved method of working they might introduce. An additional indirect advantage to the country, which is more far-reaching than the exaction of a high royalty, would be the reduction of working costs, thereby permitting much lower-grade ore to be mined throughout South Africa.

If working costs today could be brought down to \$2.50, instead of \$4.50 per ton, South Africa would benefit, because more people would be employed in the mining industry; the revenue from the Government-owned railways, as well as from the customs, would be increased. The needs of a larger population will stimulate agricultural development. So it may be taken for granted that Mr. Kotze and the Government will do everything in their power with this object in view and will favor rewarding and not penalizing efficient management, recognizing that by adopting this policy the Government will assist in bringing about the working of larger areas that are today unprofitable.

For the benefit of those who are not conversant with South African mining law, it might be as well to state that in the Transvaal a mine is worked out when all the ore within and under the four sides of a property is exhausted; it does not mean that the lode has come to an end. All that has happened is that the same lode is being worked, only by a different owner, on the adjoining property. The apex law does not apply in the Transvaal, although it does in Rhodesia.

On the scheme of finance, I agree with you; the present proposal seems a little like placing the cart before the horse. Certainly, the big risk is taken when your fortune-hunting shaft starts on the long expensive journey in search of the deep-level lode of the Far East Rand. If when the shaft meets the fickle Jade she is found to be good and attractive, there is little risk, and one can expect that all will go well and prosper for ever after.

Your statement that Mr. Kotze takes 60% as being the productive area should read 40% productive, and 60% unproductive, as an average, the ground so far having been 15 to 85% profitably productive, but he points out that in some cases this will prove too optimistic or too drastic, whichever the case may be.

The exploitation of the claims in the Far East Rand, favorably situated, although requiring a large amount of money, involves little speculative risk, especially true when the areas are sufficiently large and compact. As in all mines, there are rich and lean areas. In the case of the Far East Rand, the success attained by the mines that have produced \$215,000,000, up to the end of 1915, from 26,682,000 tons of ore milled, ensures

confidence and establishes this part of the Rand as safe and sound for the investment of capital in mining ventures.

W. KARRI DAVIES.

San Francisco, October 10.

The McDougall Furnace

The Editor:

Sir—In your issue of September 9, you are good enough to include me in a list of authorities on the spelling of Arthur McDougall's name. Regretfully I must deny the soft impeachment. The authority for the spelling used in my 'Recent Copper Smelting' was the proof-reader, who injected a ray of decision into the fog of uncertainty by asserting that the matter had been carefully gone into by someone some years before and thus decided. You have, by the way, overlooked a fourth variant, M'Dougall, used in the *Encyclopædia Britannica*.

Now that you have re-opened the question, I have been interested to secure more definite authority and have consulted the records of the British Patent-Office. I find that on January 25, 1868, patent No. 270 was issued to Arthur McDougall, of the firm of McDougall Bros. of Manchester and London, for his "apparatus for burning, calcining, or roasting sulphur, ores, or other materials." British patent specifications do not give a facsimile of the signature, as those in this country do, but it is probably safe to assume that the spelling there given is correct.

The application and its accompanying drawings show a furnace, 6 ft. in diameter, essentially identical with the present form, with the exception that only one hearth was used, heated from beneath by a fire-box. McDougall specifies that if one hearth is not enough, others may be superimposed on the first. No mention is made of any provision for cooling the cast-iron rabble-arms, and this defect led to its failure in practice. In the 1879 edition of Lunge's 'Sulphuric Acid and Alkali,' the author says that the McDougall furnace is theoretically the most perfect for burning pyrite 'smalls,' but that it was unsuccessful because of the difficulty in replacing the rabble-arms and because it made so much dust as seriously to contaminate the acid in the chambers. Apparently it never came into favor in Europe, and not until J. B. F. Herreshoff designed a furnace in which the rabble-arms were separable from the central shaft was it successful in America for burning pyrite. Small furnaces, 10 ft. 10 in. diameter, only roasting five or six tons per day, were used for roasting copper ore in the Heinze smelter at Butte. In 1898 Frank Klepetko built a 16-ft. Herreshoff furnace at Great Falls. This was a 40-ton furnace, with an air-cooled central shaft and solid arms, and the increased size and rate of driving naturally made it run so hot that the rabble-arms became warped and distorted. Both air and water-cooling of the arms was considered, but Mr. Klepetko's judgment was that the latter was preferable, so this furnace was

shut-down and re-built into the Klepetko-Evans furnace, with water-cooled central shaft and rabble-arms. More recently Utley Wedge has perfected the use of an air-cooled shaft and rabble-arms. These three types are really only modifications of McDougall's idea, and it is interesting to note that his patent claims cover "a self-acting rake or stirrer arranged, combined, and operating substantially as hereinbefore described," and also "the general combination and arrangement * * * as described and illustrated." Presumably he never made any money out of his patent, and it would seem, in view of the general use of his type of furnace for roasting copper ore and pyrite, that the least we can do for him is to spell his name correctly.

If you are in the mood for straightening out the Maes, you might also come to the rescue of Mr. Macquisten, whose tube concentrator is frequently referred to as the MacQuiston tube, or some other variant of his name.

THOMAS T. READ.

New York, September 21

Elmore and Flotation

The Editor:

Sir: I have read with much interest Mr. A. Stanley Elmore's article in your issue of September 24.

I should be the last to depreciate the share which the Messrs. Elmore have had in the development of the art of flotation. Few will deny that their contribution has been greater than that of any other individuals; and that it has received inadequate recognition, both morally and financially.

Inventors are prone to think that their particular addition to the world's stock of knowledge was the real starting-point of all progress. But when Mr. Elmore claims his brother's first patent (doubtless an independent invention, although so much later than Everson's), involving the incorporation of oil into an ordinary mill-pulp, to have been the actual beginning of oil-flotation, he makes a claim that, in my opinion, is unwarranted. It is perfectly true that the first Everson patent provided first for mixing dry ore with acid, oil, and a small quantity of water, and subsequently washing the oiled pulp in a large quantity. Dr. Everson, the inventor, was a physician, and naturally used the physician's way of mixing, by first using sufficient water to make into a paste, and adding the bulk of the water subsequently. This however is a mere matter of manipulation; which might have been, and probably was, modified when the inventor came to Colorado and saw that in actual mills the ore and water came to hand ready mixed for use. Dr. Everson's final method of manipulation on a laboratory scale, according to the recollection of persons still living, seems to have involved the use of a large glass jar fitted with an egg beater for agitation of the ore, oil, and water, and also with a glass tube for introduction of air.

Here we have the germ; to my mind all later developments were such as would, in actual operation, naturally follow from it. They are, to quote from Mr. Elmore,

"in the nature of ordinary development of working details." For all that, they have made all the difference between success and failure.

GEORGE E. COLLINS.

Denver, October 2.

The Mexican Commission

In a memorandum submitted to American members of the American-Mexican Commission by the conference of American-Mexican mining and smelting interests, of which William Loch, Jr., of American Smelting & Refining Co. was chairman, it was stated that 45 companies concerned have sustained a loss in depreciation of property in Mexico and actual wastage of more than \$7,246,031 in the years of idleness. Upward of \$16,088,363 has been lost in wages alone to the Mexican people. The mining and smelting industry conducted by Americans in Mexico is practically at a standstill. This is shown by number of employees, pay-rolls, and metal production for first half of this year compared with the year 1912, taken as the last normal year. The 45 companies' cash investment in properties is \$125,000,722, with plants in 14 states:

	First half of 1916	Year 1912
Aggregate pay-rolls (U. S. currency).....	\$3,671,302	\$18,726,090
Number of Mexicans employed.....	6,000	62,216
Copper matte or bullion, tons.....	23,156	74,984
Zinc ore, tons.....	11,183	46,765
Lead bullion, tons.....	2,928	70,929
Silver, ounces.....	6,200,339	31,892,735
Gold, ounces.....	39,895	252,843

The burden of new taxes is shown by the following comparison between taxation on basis of rates and laws promulgated under the constitution and in force in 1912, and actual and estimated effect of rates promulgated by the *de facto* Government, based on production occurring in 1912, for the 45 companies:

	Constitutional law, 1912	Arbitrary decree, 1916
Pertenencia.....	\$96,629	\$569,738
Export and all other taxes.....	1,629,971	7,096,052
Total.....	\$1,726,600	\$7,665,790

Under existing tax decrees, companies mining and treating large tonnages of low-grade ores, which constitute the most extensive mining operations in Mexico, will be unable to resume operations, since export taxes on the metal, which in the new rates are shown as 10% and 5%, often work out as high as 50%. This is so because no allowance is made for cost of transportation, treatment, and marketing. *Boston News Bureau.*

CHROMIUM production of New Caledonia, near Australia, was 19,216 metric tons in the first quarter of 1916. This sells for \$9 per ton in London, 50% Cr₂O₃ content.

PLATINUM has been discovered in the Sierra la Ronda, southern Spain, and the average of 50 drill-holes was 3 grains per cubic metre, or 31 grains per cubic yard.

The American Institute of Mining Engineers as Censor—A Protest

By W. H. Shockley

On page 17 of the volume on mining in the transactions of the International Engineering Congress and in my article on 'The Economic and Social Influence of Mining' will be found the following note:

"The writing of this paper was completed in June 1915, and when it was presented at the meeting of the International Engineering Congress, in September 1915, it contained statistics, drawn chiefly from volume 16 of the Immigration Commission reports, which seemed to show that the pay of the anthracite miners in Pennsylvania was less than the amount required for physically efficient living. These statistics were claimed to be erroneous by the Anthracite Section of the American Institute of Mining Engineers and the Section asked that they be omitted. The same request was also made by the American Institute of Mining Engineers.

"In view of the fact that since the paper was written the wages of the anthracite miners have been materially increased and their hours of labor reduced to eight, daily, and, furthermore in order to avoid controversy in the transactions of this Congress, the author has consented to omit these statistics and his remarks, indicated by asterisks on this and subsequent pages, relating to the anthracite miners' wages. This step is taken by the author in deference to the request of the Committee of Management of the Congress and without prejudice to his own views in the matter."

Herewith are the remarks that were omitted:

"PENNSYLVANIA ANTHRACITE REGION

		Average yearly earnings
16 heads of families, native born.....	(23)	\$732.00
416 heads of families, foreign born.....	(23)	447.00
432 average of both of the above.....	(23)	457.00
99.6% of the 969 employees 18 years and over earn less than		1,000.00
43,201 contract miners	(99)	728.84
33,292 miners, laborers	(99)	495.92
48,024 other inside men	(99)	541.23
29,554 outside workmen	(99)	526.88
16,238 breaker employees	(99)	358.17
(23) Immigration Commission Report, Vol. 16.		
(99) Anthracite. Scott Nearing, page 101.		

"In the table of the wages of the miners on page 19 it will be noted that the general average of 432 heads of families in the anthracite region is given as \$457; this figure is from the report of the Immigration Commission (23); the data for that report were probably collected in 1908-1909; since then there has been a 10% advance in wages (in 1912), and hence this average of \$457 should now be \$503. The other statistics relating to the anthracite region are from the report of the Secretary of In-

ternal Affairs for the State of Pennsylvania for 1912 (99); the average of the whole 170,309 mentioned by him is \$560.02, which is not vitally different from the average of \$503 already given. Judging from the statements of many investigators of the cost of living, it should require from \$700 to \$780 to support a family properly in the anthracite region. Hence, it seems probable that a number of the 432 heads of families whose annual earnings average but \$503 cannot support their families properly—that is, their wages are inadequate.

"The statement in regard to wages made by the Immigration Commission and the inference from the rate of wages and the probable cost of living that the pay of the anthracite miner is inadequate are denied by the anthracite mine operators, who state (100)* "It is a well-known fact that as an average there is not a more physically fit community in the United States than that composed of the anthracite miners. The anthracite operators further state that the average wages are now (1915) much higher than those given by the Immigration Commission; they point out that the Anthracite Strike Commission found that the wages of the contract miners of the Lehigh Coal & Navigation Company were \$738.84 and that all the underground employees of the same company earned \$519.20; this was in 1901; since that date advances in wages have been made, and allowing for these advances and assuming that the same number of days have been worked, the wages of the contract miners would now be \$894 and the wages of the underground employees \$628. Unfortunately, the anthracite operators make no statement as to the nationality of the employees or as to their marital condition, therefore no direct comparison can be made between the figures of the operators and those of the Immigration Commission.

"But, whatever conclusion the student may come to as regards the sufficiency of the pay of the anthracite coal-miner, there is no doubt that many of our workmen are poorly paid; this inadequate pay of the workmen exists in many industries and is said to be largely due to the lower standard of living of the 'new immigrants'."

As stated in the note above quoted, these remarks were omitted in deference to the request of the Committee of Management of the International Engineering Congress, this request having been prompted by the following resolution of the directors of the American Institute of Mining Engineers, passed at New York on June 23, 1916.

"Voted that it is the sense of this meeting that if the paper of W. H. Shockley to the International Engineering-

* (100) Letter from E. W. Parker, Director Anthracite Bureau of Information, to R. V. Norris, Chairman of Anthracite Section, A. I. M. E., Oct. 13, 1915.

ing Congress which has been objected to cannot be changed to meet the views of the Pennsylvania Anthracite Section, it should not be published."

In a letter to the Secretary of the Institute, on February 24, 1916, I pointed out that my statements were statistics from the official reports of the United States government and from the State of Pennsylvania and that I merely drew the obvious inference that if the proper cost of living is \$780 yearly and the annual wages of the heads of families average but \$503, or even \$600, there must be a good many heads of families who do not have enough to live properly.

I also stated in this letter: "It is my earnest desire to give a truthful account of the opinions on both sides of this disputed question and I am quite willing to include in my paper any further remarks that the Anthracite Section of the A. I. M. E. may wish to make with regard to wages and living conditions, and I am willing to accept any reasonable modifications of my own remarks. My own opinion is that in denying me the privilege of quoting official reports you lay yourself open to the reproach of taking a partisan view of a disputed question and of violating the ancient legal maxim: *Audiat ut altera pars*. (Let the other side be heard.) And it does not seem to me that it is the proper function of a technical society to suppress evidence, as, according to my view, you will suppress it, if you deny me the right to quote these governmental statistics."

After fully considering all the issues involved and after consultation with a number of engineers and economists, I am still of the opinion that there was no valid reason for the action of the Institute in requesting the International Engineering Congress to modify my paper to suit the dictum of the Anthracite Section. I still feel that I was justified in publishing these statistics and remarks, and this opinion was supported in a meeting held at the International Engineering Congress headquarters in San Francisco on June 12, 1916, at which were present R. E. Cranston, William S. Noyes, T. A. Rickard, and Frank H. Probert, members of the Institute, and J. S. Hess, E. J. Dupuy, and W. A. Cattell, officials of the Congress. This meeting was called to consider the following telegram:

"Wilkesbarre, Pa., June 11, 1916. W. F. Durand, Chairman International Congress, San Francisco, Calif. Your letters and Mr. Shockey's revision have been considered by the Board of the Anthracite Section of the Institute. The Board insists that Mr. Shockey's rights do not include the right to misrepresent conditions in the anthracite region of which he knows nothing. They unanimously resent his statements. Are prepared to refute them and still insist that all reference to the anthracite region be expunged from the paper by order of the board of directors of the anthracite section of the American Institute of Mining Engineers. Signed, Paul Sterling, Secretary."

After the meeting a telegram was sent by the Secretary of the Congress to the chairman, W. F. Durand, then at Brooklyn, as follows:

"After careful consideration all present fully agreed

Congress Committee justified in publishing Shockey's paper as amended."

However, Mr. Durand, on his return from New York, did not consider it advisable to oppose the resolution of the directors of the Institute as quoted above, and after discussion I consented to omit the remarks and statistics in question and to replace them by the note appearing at the beginning of this communication. I distinctly reserved the right to deal with the controversy elsewhere as I saw fit.

On thinking the matter over, the action of the Institute in seeking to suppress these well-known statistics seems to me not only futile but stupid, and this for the reason that when the Institute passed the resolution on June 23 similar statistics had been published and read by all of those interested in the question. Such statistics were scattered broadcast in the book 'Anthracite,' written by Scott Nearing, which book was circulated as a brief by the anthracite miners before their conference with the anthracite operators and the matter was well summarized by J. P. White, president of the United Mine Workers, in his statement to the press, issued on February 21, 1916, wherein he stated:

"The annual earnings of miners, laborers, other inside men and outside workmen average not more than \$600 a year. The United States Bureau of Labor and Statistics estimates that a man cannot support his family in decency for less than \$750."

As is well known, the conference between the miners and the anthracite operators was held in New York from February 21 to April 30, 1916, resulting in increased wages and lessened hours of work; this agreement is to last for four years. Anything published now will have no influence on any contract that may be made at the expiration of the present agreement. Hence, there can be no possible harm in my publishing the statistics here. And it seems to me that I owe it to my fellow-members of the Institute and to the general public to give the details of this controversy in order to find out whether this censorship of the Institute is for the best interests of all concerned, that is, the anthracite operators, miners, the engineers, and last, but most important, the general public. In other words, is it best that the directors of a technical society shall act as censors as regards statements relating to labor questions, or should the various technical societies, in this case the Institute, stand for free speech and open discussion? I hold that the action of the Institute in censoring Government statistics is contrary to public policy and, in this particular case, most ill judged. It also seems to me that the publication in my article of these Government statistics offered the Anthracite Section a very favorable opportunity to correct any false statements and that they should have welcomed the publication instead of attempting to suppress it.

Prominent in wolframite, the tungstate of manganese and iron, in Argentina is of growing importance. The mineral is found almost exclusively in veins of quartz with mica.

The Wilmington Decision on Flotation—II

Text of Opinion by Judge Bradford in the U. S. District Court

The weight of the evidence is that the quantity of oil to ore necessary for the conduct of the process specified in the Froment patent would be from 12% to 15% of the weight of the ore, and this seems to accord with the statements in the patent that a "kind of metallic magma" is formed and that "the metallic spherules pressed one against the other, will become grouped in a magma clearly separated from the remainder of the liquid." These statements, I think, are inconsistent with any idea that under the Froment process the metallic particles were coated with oil of the extreme thinness characterizing the process of the first patent in suit; the thickness of the film in that process, according to scientific evidence, being only one one hundred thousandths part of an inch and imperceptible to the senses, as compared with a thickness of from sixteen to thirty-two one hundred thousandths of an inch in the Cattermole process and from eighty-five to two hundred and forty one hundred thousandths of an inch in the Froment process. The British Froment patent is in substance the same as the Italian patent and in neither of them does it appear that there was present in the Froment process the very minute quantity of oil of the first patent in suit. The Froment British patent was assigned to Ballot, one of the patentees in the first patent in suit, November 17, 1903, for the benefit of the plaintiff when organized, and in the assignment Froment covenanted that he would forthwith forward or hand to the purchaser the "plans and diagrams of the plant relating to the said invention with a full description of the working of the process." Pursuant to this covenant there were transmitted to Ballot plans and diagrams and a paper, in evidence, containing a "description and instructions for the concentration of ores" under the Froment process. It is dated December 29, 1903. The instructions recommend the use of oil in proportions varying from 1% to 3½%, according to the different percentages of metal in the ore. Notwithstanding the low percentage of oil mentioned in the Froment description, I have reached the conclusion that it contained no disclosure of the process of the first patent in suit. The evidence on the subject of the Froment description is voluminous and conflicting, but there are facts and circumstances which have satisfied me that the process of the first patent in suit was not discoverable from that description by men skilled in the art of ore concentration. Dr. Liehmann states that the Froment process as disclosed in the patents as well as the Froment process as disclosed in the description are "incapable of being carried out successfully." There is uncontradicted evidence that Sulman, Picard and Ballot, after the assignment of the Froment British patent and the receipt of the Froment description and instructions,

made persistent efforts to operate the Froment process successfully, but only met with failure, and that the model apparatus sent by Froment to Ballot was treated as worthless and discarded or "scrapped." Sulman, Picard and Ballot were scientific men of large experience in the art of ore concentration, and had the Froment patents or description disclosed or suggested the process of the first patent in suit, it is to be assumed that they would have utilized it instead of prolonging their attempt until March, 1905, to perfect granulation under the Cattermole process. The fact that they did not utilize it affords the strongest evidence that the Froment description did not suggest a process in which the minute quantity of oil required by the first patent in suit could be successfully used in ore concentration.

The defendant relies on patent No. 793,808, of July 4, 1905, to Sulman and Picard, for 'Improvements in or relating to ore concentration.' The patent states:

"The present invention relates to the concentration of ores by separation of the metalliferous constituents and graphite, carbon, sulfur, and the like from the gangue by means of oils, grease, tar, or any similar substance which has a preferential affinity for metalliferous matter over gangue. According to this invention we utilize the power which is possessed by films or bubbles of air or other gas of attaching themselves to solid particles moistened by oil or the like."

Two methods of carrying out the invention are stated. The first is as follows:

"According to one method of carrying out our invention suitably-crushed ore is suspended in water. To this suspension a proportion of oil, grease, or tar (hereinafter referred to as 'oil') is added and duly mixed with the mass by any suitable means in quantity insufficient to raise the oiled mineral by virtue of the flotation power of the oil alone. A suitable gas is now generated in or introduced into the mixture, such as air, carbonic-acid gas, sulfuretted hydrogen, or the like. For example, bicarbonates or carbonates, either soluble or insoluble in water (preferably the latter) or easily-decomposable sulfids and the like may be used with acid solution. In such cases, if desired, the addition of acid may be made to the mixture after the addition of the gas-producing reagent. In the case of solutions containing free alkali the addition of acid sufficient to neutralize this must be made before the gas is produced. If desirable, gaseous bubbles may be produced by electrolytic methods or by means of various other known reactions."

The second method is stated as follows:

"According to another method of carrying out this invention the oil is not added alone; but the pulp is submitted to the action of a current of air or other gas bub-

bles, the air or other gas being first suitably charged either with the vapor of a volatile oil, such as petroleum of low boiling-point, or with the spray of any other suitable volatile or non-volatile or fixed oil or the like. The oil may be sprayed or reduced to a state of such fine division that minute globules of the same can remain temporarily suspended in an air or other gas current by the use of any suitable spraying or atomizing device and the air-current introduced into the ore-pulp, preferably at the bottom, by means of a pipe or pipes provided with suitable perforations or by other suitable contrivance. The minute oil globules or the condensed vapors or volatile oils attach themselves to the metalliferous particles in preference to the gangue."

The patent then states:

"The oiled metalliferous particles resulting from either of the processes above described have the power of attaching to themselves with a greater comparative strength than the gangue particles the films or bubbles of gas which exist in the mass and are thus raised to the surface of the liquor by gaseous flotation. They can then be removed by skimming or other suitable means. The gangue particles unwetted by oil or grease are not floated up with the oiled mineral particles, and thus in the main remain at the bottom of the vessel containing the mixture. The oil can then be removed from the oiled mineral by any suitable known means."

There are certain features in this process as described similar to features in the process of the first patent in suit. The amount of oil coating the metallic particles being insufficient to raise them through the flotation power of the oil alone, gaseous bubbles, whether generated in the mixture, or introduced into it through the perforated spiral coil, attaching themselves to the oiled metallic particles, rise to the surface with those particles, so as to be removed by skimming or other suitable means, the gangue particles remaining in the main at the bottom of the vessel containing the mixture. This process patent, issued to Sulman and Picard upon an application filed October 5, 1903, affords cogent circumstantial evidence of the patentability of the process of the first patent in suit. I have been unable to read the description of the patent immediately under consideration without reaching three conclusions: first, that Sulman and Picard had conceived an idea, though imperfect, of an air flotation of the metallic particles; secondly, that they had no conception whatever of the possibility of conducting such a process with the minute quantity of oil specified in the first patent in suit; and thirdly, that they contemplated the use of a very much larger proportion of oil. In view of the fact that both patentees in No. 793,808 were two of the three patentees of the process of the first patent in suit, it is so improbable as to amount to a moral impossibility that for nearly a year and a half after the filing of the application for patent No. 793,808 they should have devoted their attention and efforts to the solution of the problem of the proper quantity or proportion of oil to be used in securing improved granulation in the Cattermole process, and have been astonished

at the making of the discovery in March, 1905, if they had recognized or believed that an economical and efficient process of ore concentration could be carried on by the use of oil amounting to only a fraction of one per cent. Any further discussion of patent No. 793,808, I think, is unnecessary.

I have found nothing in the prior art to anticipate the process of the first patent in suit or to negative invention. Objection has been made that the disclosures of the patent are not sufficient, in that the application of the process to different ores necessitates some difference in treatment involving a variation in temperature, or in the amount of acid or of oil, and the patent omits to specify the degree or amount of such variation with respect to the treatment of the different ores. But to require of an inventor such a specification would be to demand an impossibility. The patent recognizes that different ores may require a different treatment. The description states:

"The proportion of mineral which floats in the form of froth varies considerably with different ores and with different oily substances, and before utilizing the facts above mentioned in the concentration of any particular ore a simple preliminary test is necessary to determine which oily substance yields the proportion of froth or scum desired. * * * The minimum amount of oleic acid which can be used to effect the flotation of the mineral in the form of froth may be under 0.1 per cent of the ore; but this proportion has been found suitable and economical."

And claims 1 and 12 mention oil amounting to "a fraction of one per cent." A close or exact adjustment of quantities and proportions of oil in the treatment of different ores within the limits prescribed in the patent is a matter calling, not for the exercise of inventive genius, but for the skill of the metallurgical engineer conducting or superintending the operation. In *Mowry v. Whitney*, 14 Wall. 620, the court said:

"The specification, then, is to be addressed to those skilled in the art, and is to be comprehensible by them. It may be sufficient, though the unskilled may not be able to gather from it how to use the invention. And it is evident that the definiteness of the specification must vary with the nature of its subject. Addressed as it is to those skilled in the art, it may leave something to their skill in applying the invention, but it should not mislead them."

Some embarrassment in the treatment of this case has been caused by the use of different adjectives and descriptive phraseology as applied to the same thing. If a patent for a process of ore concentration, or any other process, clearly sets forth the ingredients and the practical steps to be observed in conducting it the misuse of terms as applied to the operation of natural laws involved in the process is immaterial. In the administration of justice it is the aim of courts to deal with substance and not to be influenced by mere form not calculated to mislead as to substance; and where a material and substantial thing is plainly identified in the patent

claims and description a mistaken misnomer is harmless and negligible. Inventors are not required to understand the natural laws under which new and useful results are obtained from ingredients, elements, apparatus and manipulation requisite for the conduct of the process. There are occult laws, unknown and inexplicable, to which tangible results must be attributed. In the nature of things an inventor, so long as he clearly sets forth the practical means and steps for securing those results, does all that the law requires or can reasonably be expected of him. So, it is unimportant that to the same thing one name may be applied by one person and a different name by another, the identity clearly appearing. The truth of this statement has been strikingly exemplified in this case in the language of patents and other publications, judicial decisions, the oral testimony and the arguments of counsel.

During the trial a large number of experiments were made for the purpose of illustrating ore concentration processes described in patents and other printed publications of the prior art. Such experiments are illuminating and helpful, or deceptive and misleading, according to the conditions under which they are performed. As a general rule, in such experiments processes of the prior art should be illustrated by means of apparatus of the prior art in which such processes were conducted at or about the time of invention and under the conditions then understood and observed. To construct apparatus long after, and in view of subsequently acquired knowledge, in order to show a prior process tends to produce embarrassment and confusion touching the nature and operation of the process inquired into. In *Naylor v. Alsop Process Co.*, 168 Fed. 911, the circuit court of appeals for the eighth circuit said:

"An expert, however, cannot take a process patent which has never been applied industrially and work the process in his laboratory and discover therefrom something which is not disclosed on the face of the patent, and then transfer that experience back to the time of the patent, and make it a part of the prior art for the purpose of defeating a meritorious invention."

In *Schmertz Wire Glass Co. v. Western Glass Co.*, 178 Fed. 977, the court said:

"By using twentieth century magnifying glasses, a nineteenth century method has been found efficient, which never was so before, and the immensely important point of view of an advanced art is thus unfairly used to discover an original conception never acted on or made anything of, and which never had any practical or beneficial existence."

The material question for the court is not whether any given apparatus is capable, under manipulation employed in view of existing knowledge, of carrying on the prior process inquired into, but whether the process was carried on as a part of the prior art, and, in case of an ore concentration process, by way of illustration, under what conditions as to ingredients, strength and extent of agitation and other essential factors; and only so far as those conditions are reproduced and faithfully observed

in demonstrations in court, due allowance being made for the difference in the requirements of mill operations, is the experiment entitled to probative force. The difference between the conduct of the process in the mill and the necessarily interrupted or broken character of the process as disclosed in experiments in court and laboratory tests in subsequently constructed apparatus must be borne in mind in determining the weight to be given to such experiments or tests.

On the whole I am satisfied that the first patent in suit must be sustained as to claims 1 and 12, but not as to claim 9. The two former are definite, specifying and limiting the amount of oil to be used; claim 1 mentioning "a small proportion * * * amounting to a fraction of one per cent on the ore," and claim 12 "a fraction of one per cent of oil on the ore." Claim 9 mentions "a small quantity of oil." This is so indefinite as to render the claim void, unless on consideration of the patent as a whole the claim can by construction be limited to the use of oil amounting to only a fraction of one per cent. The patentability of the process of the first patent in suit resides in the use of oil in the extremely minute proportion disclosed in the descriptive portion of the patent to effect separation of froth with its metallic particles from the remainder of the mixture by flotation. The amount there disclosed is not in excess of "a fraction of one per cent on the ore" and may be only one-tenth of one per cent on the ore, or even less. If, then, by construction claim 9 should be so limited as to be restricted to the use of oil amounting to only a fraction of one per cent on the ore, that claim is in substance, though not in exact phraseology, the same as claim 1 for the reason that in any event from the nature of the invention it would be necessary to read "by flotation" into claim 9, if in other respects valid. But a limitation by construction producing such a result is inadmissible. It is suggested by one of the plaintiff's counsel in his consideration of claim 9, that one for the purpose of securing immunity from the consequences of infringement might use an oil useful in the process, and add to it an oil not useful as applied to his particular ore, and, on being sued for infringement contend, "I am using 1.1% of oil. I do not infringe. I am using more than a fraction of 1% of oil." But the existence of this possibility does not, I think, warrant such a construction of claim 9 as is urged; for the disclosure of the patent does not extend to the use of 1.1% of oil, but is limited to a fraction of 1%. If it be assumed, however, that the claims in suit contemplate and require the use of efficient, as distinguished from inefficient, oil, and if in the case suggested an inoperative oil should be used by way of addition to the efficient oil so contemplated and required it might be a question, upon which, however, no opinion is here expressed, whether the addition of the inoperative oil to the efficient oil could be treated as an increment to the amount of oil so contemplated and required, operating as a shield to protect the wrongdoer. But this question would arise in a suit based upon claim 1 or 12, as well as in a suit based upon claim 9, were it proper by construe-

tion, in order to save it, to limit "a small quantity of oil" to a quantity of oil amounting only to a fraction of one per cent on the ore, and therefore fails to require or justify the suggested limitation of claim 9, without which it must fall.

On the question of infringement of the first patent in suit I have no doubt. It was practically admitted by counsel for the defendant in opening the defense that it had infringed the three patents in suit by its operations at Miami within four months next before the filing of the bill; he stating "in the first installation which was made at Miami, we make no serious contention that it did not represent the operations set forth in the three patents in suit." It appears that the infringing operations were carried on in apparatus built in imitation of the plaintiff's standard machine. But the defendant denies that it infringed by its concentration of ore in its pneumatic flotation plant through its practice of the process of patent No. 733,808 of July 4, 1905, to Sulman and Picard, hereinbefore discussed, as modified by the use of what is known as the Callow cell. Counsel for the defendant, however, stated with respect to the process of the patents in suit and the process as carried on by the defendant under the Sulman and Picard patent, with the apparatus of the Callow cell:

"The broad principles are the same in both. In both we have the pulp, consisting of ore held in suspension in water. In both the water is modified to lower its surface tension. In both the buoyancy comes from air-bubbles."

The defendant in its operations also used the minute proportion of oil mentioned in the first patent in suit. It does not use acid in its process; but this fact is immaterial so far as the question of infringement is concerned for the reason that it appears both from the claims and the description of that patent that the use of acid is optional, the description stating that "the water in which the oiling is effected is preferably slightly acidified," and claims 1 and 12, as well as claim 9, unlike a majority of them, not requiring acid. The defendant's counsel also stated that the difference between its process and that of the complainant "comes after the air bubbles have attached themselves to the mineral particles." I do not think there is any such difference between the processes as to negative infringement. It was in substance admitted on the part of the defendant that if the first patent in suit is a pioneer patent and properly drawn the operations carried on at Miami were an infringement. Whether that patent is technically a pioneer patent or not, it certainly was highly meritorious and, I think, partook of the nature of a pioneer patent so far as the very successful use of oil amounting to only a fraction of one per cent is concerned. Its claims merit much liberality of construction and when so construed embrace the operations of the defendant at Miami. The purpose of each process is the concentration of the ore through the separation of the metallic particles from the gangue. In the plaintiff's process the separation is effected through the rising of air-bubbles to which are attached

the metallic particles, through the mixture to the top, and the formation of a froth or scum on the surface, which can by simple means be removed with the contained metallic particles. In the defendant's process the separation is effected through the rising of air-bubbles to which are attached the metallic particles through the mixture of the top and the floating away into a launder of either the original bubbles to which the metallic particles were first attached or succeeding and on-coming bubbles which have caught and buoyed up to the surface the metallic particles escaping from bursting bubbles. By the use of a launder a recovery of the metallic particles is readily effected. The defendant contends that since its abandonment of its original infringing process at Miami above referred to, it has not and does not infringe the first patent in suit, for the reason that it does not in its process produce the coherent and permanent froth of the process of that patent. It appears from the evidence, it is true, that the bubble froth in the defendant's process is not as coherent and permanent as the froth of the process of the first patent in suit; but both are mineral froths, and that of the defendant is sufficiently permanent to effect through air flotation an efficient separation of the metallic particles from the rest of the mixture. Air-bubbles, however produced, in water not modified or contaminated—pure water—on reaching the surface will immediately collapse, and the formation of bubble or air froth is impossible; but air-bubbles in modified water will not instantly disappear on gaining the surface. The degree of their permanency after reaching the top largely depends on the degree of modification of the water.

There has been much expert evidence relating to the subject of surface tension to the effect that in the case of pure water it is so great as to cause the instant collapse of bubbles of air rising to the surface; but that through modification of the water, the tension is so reduced in force as to permit the continued existence for a greater or less period of bubbles of air reaching the surface. The water in the ore pulp of the defendant's process is strongly modified and of necessity the bubbles on reaching the surface do not and cannot instantly disappear; but, on the contrary, in accordance with the operation of natural laws about which there is no conflict, persist and continue on the surface as a bubble or air froth. But whatever may be the true explanation of the phenomenon of the continuance and disappearance of escaping bubbles, the fact remains that the defendant's process discloses a froth consisting of bubbles which have passed through modified water to the surface of the mixture, and float thereon, and with their freight of metallic particles flow over the edge of the containing vessel into a launder, thus effectively separating the valuable mineral from the gangue particles. Coherency and permanency in a froth admit of degrees, and such a degree as insures by air flotation an efficient and final separation between the metal and the gangue, whatever may be the duration of the froth, comes within the process of the first patent in suit.

The defendant further insists that its process lacks

violent agitation which it claims is an essential of the process of the first patent in suit. Each of the twelve claims of the patent mentions as an element of the process "agitating the mixture," but not one of them mentions violent agitation. It is, however, urged that the descriptive portion of a patent for a process must contain a full and fair disclosure of the patented invention the claims must be read in the light of the description, and as violent agitation is included in the description the claims with respect to agitation must be limited to violent agitation. But the description nowhere mentions "violent agitation" or uses any equivalent expression. It mentions "vigorous agitation," and states that in the case of the application of the patented process to an ore containing "ferruginous blende, galena, and gangue consisting of quartz, rhodonite, and garnet," the mixture is "briskly agitated." It also describes as a part of the apparatus for carrying on the process a "rotatable stirrer." But I do not find in the description any specification of any rate of speed for the rotatable stirrer, or of any standard for the determination of what constitutes a "vigorous agitation" of the mixture, or a specification of any test for ascertaining whether the mixture is "briskly agitated." All these matters were left to the judgment and skill of the metallurgical engineer conducting or superintending the operation of the process, involving empirical investigation to reach the best results. The strength of agitation referred to in the description clearly admits of different degrees, varying from one another in the application of the process to different ores and under changing conditions. There is no room for doubt that agitation of the mixture in the process of the defendant is sufficiently vigorous or brisk to insure efficient ore concentration by an air flotation process such as is accomplished by the complainant by agitation under the process of the first patent in suit. This being true the use of mere adjectives in the descriptive portion of the patent with respect to agitation is unimportant. In order that the bubbles in the pulp mixture may come in contact with the metallic particles there must be such movement between them as cannot be wholly accounted for by selectivity as between them, and their movement so far as not accounted for by selectivity is the result of agitation; and whether such agitation results from the stirring or beating of the mixture or the forcing or admission of air into it is immaterial; for what this court is dealing with is not an apparatus patent but a process patent.

Patent No. 1,104,755, of July 21, 1914, to John M. Callow, covers apparatus relating to ore concentration. The evidence shows that the defendant in its concentration of ore in its pneumatic flotation plant employs the process of patent No. 793,808, of July 4, 1905, to Sulman and Picard, hereinbefore discussed, as modified by the use of certain apparatus substantially the same as a portion of the apparatus, the operation of which is described in the above-mentioned Callow patent, as follows:

"From the foregoing, it will be understood that I employ no mechanical propellers for producing the neces-

sary agitation and beating into the froth of large volumes of air, but that I depend upon the compressed air admitted through a porous body which has the function of splitting up the air into innumerable fine streams and distributing these fine streams over and into substantially the entire surface of the pulp, whereby immediately upon the introduction of the air, a more or less violent agitation or ebullition takes place and a froth begins to generate and to finally rise and form on the surface of the pulp."

The character of the agitation above described is also clearly recognized in the claims of the Callow patent.

The combination of claim 1 of the first patent in suit contains the following elements: (1) Mixing powdered ore with water; (2) adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of one per cent on the ore); (3) agitating the mixture until the oil-coated mineral matter forms into a froth; and (4) separating the froth from the remainder by flotation. The elements in the combination of claim 12 are (1) separating the mineral from gangue by coating the mineral with oil in water containing a fraction of one per cent of oil on the ore; (2) agitating the mixture to cause the oil-coated mineral to form a froth; and (3) separating the froth from the remainder of the mixture. The elements entering into the defendant's infringing process are the same as those of claims 1 and 12 of the first patent in suit. There is no escape, I think, from the conclusion, not only that the defendant infringed the first patent in suit by carrying on the process of ore concentration in its first installation at Miami in apparatus in imitation of the plaintiff's standard machine, but also has infringed and is infringing the same patent by carrying on the process of ore concentration in its pneumatic flotation plant at the same place.

The second patent in suit, No. 962,678, of June 28, 1910, to Sulman, Greenway and Higgins, is for "Improvements in ore concentration." The patentees state that the object of the invention is "to separate certain constituents of an ore such as metallic sulfides from other constituents such as gangue when the ore is suspended in a liquid such as water." This patent is distinguishable from the first patent in suit; the object of the invention of that patent being, as stated, "to separate metalliferous matter, graphite, and the like from gangue by means of oils, fatty acids, or other substances which have a preferential affinity for metalliferous matter over gangue." It appears from the patent as a whole that "other substances which have a preferential affinity for metalliferous matter over gangue" are restricted to those of an oily nature. Such substances as mentioned in the various claims of the patent are "an oily liquid," "an oily substance," "oleic acid," "oleic soap solution" and "oil." No other frothing agent than the above substances enters into the process of the patent. The essence of the invention of the first patent in suit was the restriction of the "oily substance" to "a fraction of one per cent on the ore." In the process of the second pat-

ent in suit no oil, fatty acid, or oily substance is introduced into the mixture. The description contains the following statement:

"According to this invention the crushed ore is mixed with water containing in solution a small percentage of a mineral-frothing agent, (that is of one or more organic substances which enable metallic sulfids to float under conditions hereinafter specified) and containing also a small percentage of a suitable acid such as sulfuric acid, and the mixture is thoroughly agitated; a gas is liberated in, generated in, or effectively introduced into the mixture and the ore particles come in contact with the gas and the result is that metallic sulfid particles float to the surface in the form of a froth or scum, and can thereafter be separated by any well-known means. Among the organic substances which in solution we have found suitable for use as mineral-frothing agents with certain ores are amyl acetate and other esters; phenol and its homologues; benzoic, valeric and lactic acids; acetones and other ketones such as camphor. In some cases a mixture of two such mineral-frothing agents gives a better result than a single agent. * * * The present process differs from the two before mentioned types and from other known concentration processes by the introduction into the acidified ore pulp of a small quantity of a mineral-frothing agent, that is, an organic compound in solution of the kind above referred to and by the fact that the metalliferous particles are brought to the surface in the form of a froth or scum not by mechanical means but by the attachment of air or other gas bubbles thereto. In the frothing process hitherto known the substances used to secure the formation of a mineral-bearing froth has been oil or an oily liquid immiscible with water. According to this invention the mineral-frothing agent consists of an organic compound contained in solution in the acidified water."

* * * * *

It will be observed that no one of the claims of the second patent in suit requires as an element an oily substance or liquid, as is essential in the process of the first patent in suit, and all of the claims relied on require the introduction into the mixture of "a small quantity" of a "mineral frothing agent" or an "organic mineral frothing agent." The amount of the mineral frothing agent employed in the process is not confined to a fraction of one per cent on the ore, but must be a small quantity, evidently to be determined by the metallurgical engineer conducting or superintending the operation according to the requirements of the different ores. The novelty of this invention is to be found, not in any restriction of the amount of the mineral frothing agent to any stated proportion, for there is none, but in the fact that a mineral frothing agent as the means of separating the metallic particles from the gangue is substituted for the oil, fatty acid or other oily substance essential to the process of the first patent in suit. Such substitution has produced successful results, and, I think, involved invention. Frothing agents had theretofore been used in ore concentration, but not in the absence of an oily

ingredient. Even were the grounds on which the validity of the patent can be sustained less clear, it should have the benefit of the presumption of validity arising from the grant of letters. That the defendant has infringed the claims in suit of the second patent is established by the evidence.

The third patent in suit, No. 1,099,699, of June 9, 1914, to H. H. Greenway, assignor to plaintiff, is for 'Improvements in the concentration of ores.' It states:

"This invention relates to the concentration of ores and has been applied in practice to the concentration of copper ores the object being to separate certain constituents of the ore such as copper sulfids (for example in the form of copper pyrites) or metallic copper (natural or reduced) from other constituents such as gangue when the ore is suspended in a liquid such as water. The present process is a modification of the invention described in U. S. patent to H. L. Sulman, A. H. Higgins and myself, No. 962,678, granted June 28, 1910. The process therein described is applicable generally to the recovery of metallic sulfids and like floatable metalliferous matter and in the case of lead and zinc sulfids to which the process has been largely applied it is necessary for efficient working that the pulp should be slightly acidified, and in most cases in practice the pulp is heated. It is now found that with copper ore such as an ore containing copper pyrites effective separation is obtained in the cold without the use of acid by employing as mineral frothing agents, aromatic hydroxy compounds such as phenol, cresol, or mixtures containing the same. The process of concentrating ores containing copper sulfid or metallic copper according to this invention consists in mixing the powdered ore with water containing in solution a minute quantity of aromatic hydroxy compound such as phenol or cresol but without mineral acid and in the cold, agitating the mixture to form a froth and separating the froth."

The first twelve claims of the patent are in suit, but it is unnecessary to set them forth in full. I do not find any element of patentability in the process of this patent. It is stated in the description that the process can be carried on "without mineral acid and in the cold," and "is carried out in the cold and no acid is added to the pulp." Under the second patent in suit the use of heat is optional, and no patentability can be attributed to the process of the third patent in suit on the ground that the process is carried on in the cold or without heat; for patentability can never result from the mere omission to do something, the doing or not doing of which is optional. There is a question on which a difference of opinion has been expressed, whether in the process of the second patent in suit the use of acid is also optional. The description in the patent considered alone requires the use of acid; but while five of the nine claims mention "acidified water," the remaining four do not refer to acid. It is not altogether clear to me under these circumstances whether the use of acid is not optional. But however that may be, I think that, in view of the process of the prior art an omission to use acid in the process of the third patent in suit cannot confer patentability upon it.

Necessities of the Chilean Mining Industry

*The practical results of the Chilean Congress of Mining and Metallurgy, held at Santiago on April 25, 1916, have been shown in the list of conclusions and recommendations presented to the Ministry of Industry and Public Works. Briefly these are as follows:

1. The establishment of a Federal department or bureau of mines with a self-contained organization, responsible only to the Ministry of Industry.

2. The prompt solution of problems connected with the proposed national mercantile marine laws.

3. The systematic survey of the coal and petroleum deposits of the Republic.

4. The institution of a permanent geological survey.

5. The making of a topographical map of the country and securing of data on meteorological conditions.

6. Reform of the mining code in accordance with ideas expressed by the National Mining Society.

7. The making of laws with respect to deposits of petroleum and the appropriation by the government of sufficient funds for a complete survey of petroleum lands.

8. A continuation of the survey of available water-powers.

9. A standardization of the railroad gauges for all future private or branch railways.

10. The construction of the branch railways most needed for taking out ore and the removal of the difficulties for such work in certain zones.

11. A re-organization of the Longitudinal railroad in the interests of more economical operation.

12. The making of railway tariffs that will be in proportion or relation to the mineral contents of the ore carried; the acquiring of facilities for the better and quicker loading of cars at the various stations.

13. The obligation on the part of the various districts to spend the money received in mining taxes upon roads in the mining regions.

14. The construction of first-class roads from the railroad to those mining centres that are of sufficient importance.

15. The execution of needed port works, particularly at Antofagasta and Lebu.

16. The repairing or re-construction of wharves and docks that are in bad condition.

17. The organization of a nitrate association under Federal control for the promulgation of laws for the common good.

18. The study of the supply of water in the nitrate fields, and the application of methods of irrigation.

19. The permanent organization of nitrate credits on a plan similar to that formulated in August 1914, with such modifications as experience has required.

20. The dictation of Governmental measures for the sale of nitrate in foreign countries, so that the interests

of the producers shall agree with those of the Government.

21. The securing of means whereby the large consumers of coal may take part in the exploitation of coal deposits.

22. The re-organization of mining schools, and separation of the various schools into proper classes.

23. The reform of the patent laws, whereby inventors are better protected as to title and against infringement; the division of the terms of patents; the provision for the appropriation of patents for the common good.

24. The reduction, or doing away with entirely, of customs on all imported mining necessities, particularly coal and oil, as long as they are not produced in sufficient quantities in the country.

25. The prompt approval of workmen's compensation laws.

In addition to the general recommendations, a number of special ones were made. They are:

1. The creation of an industrial laboratory for the analyses of and chemical experimentation on a small working scale with the various products of the nitrate fields, particularly with *caliche*.

2. The institution of courses applying to the nitrate industry in the higher schools of the Republic.

3. The fixing of an annual subsidy for propaganda on the use of nitrate.

4. The giving of premiums to associations of nitrate producers which develop new markets or increase the consumption in the present ones.

5. The giving of premiums to inventors who find new uses for nitrate and its by-products, especially iodine.

6. The offering of guarantees to those plants which install new and more economical systems of extraction.

7. The giving of premiums to inventors who devise more economical methods of producing nitrate.

8. The giving of a prize of \$10,000 to the author of the best work (book) on the technique and practice of nitrate production; this work to be used as a text in industrial schools of the Republic.

9. The giving of a subsidy for each ton of iron produced in the country from its ores.

10. The offering of guarantees to metallurgical plants, producing copper ingots.

11. The offering of subsidies for the construction of necessary private railroads.

12. The offering of subsidies to plants making metallurgical coke from Chilean coals.

13. The re-establishment of a subsidy to plants making sulphuric acid for commercial use.

14. The study and construction of hydro-electric plants in the nitrate fields.

15. The publication of data explaining mining and nitrate privileges.

16. The absolute prohibition of the use of alcoholic beverages and of gambling in the mining and nitrate regions.

17. The general knowledge on mining and nitrate production should be increased.

*Abstract from *Teniente Topics*, published by Braden Copper Co., Chile.

The Stoddard Mill—A Copper Concentrator

By C. B. Clyde

A 100-ton copper concentrator sounds small these days, but there is no more significant bit of evidence of the advance in the metallurgy of copper than the fact that such a plant is an economic possibility. The large increase in extraction by the new methods, the greatly decreased cost of the milling-plant, and the lower operating cost are facts hardly appreciated as yet by the smaller mine-owners.

One of the first of these companies to take advantage of the recent developments is the Stoddard Milling Company, of Stoddard, Arizona, a company formed by the Stoddard Mines Company and its neighbor, the Copper Queen Gold Mining Company, to provide reduction works for a quantity of low-grade ore that had been opened up in both mines. These properties are situated in Yavapai county, Arizona, six miles from the railroad at Mayer. The ore is chalcopyrite of medium hardness occurring as stringers and enriched masses in the Yavapai schist.

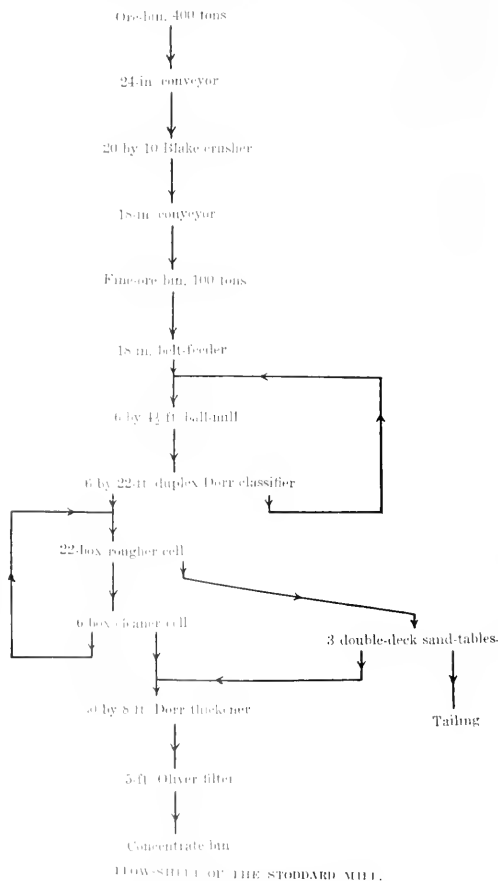

Tests on samples of the ores indicated a ready recovery of the sulphides by flotation, and on the recommendation of H. Kenyon Burch a flow-sheet similar to the Inspiration treatment was adopted. The simplicity of this flow-sheet is apparent, the only complication being introduced by the need of handling the ore from the two properties in alternate periods of several days each, and keeping the concentrates separate. This made it necessary that the concentrate thickening and dewatering division be in duplicate to allow the clean-up of a run on ore to continue for some hours after the other ore had started through the upper part of the mill.

The site selected was on a ridge midway between the two mines and about 1100 ft. from each. Flat-bottom crude-ore bins of 400-ton capacity were erected at a point convenient to both tramways, a partition separating the two ore-supplies. On top a grizzly made of rails, spaced 10 inches apart, places a limit on the size of ore dumped into the bin. The two tramways are at elevations differing by 12 ft. and are carried out over the centre of the bin on a wooden trestle.

Ore is drawn from the bin through rack and pinion gates into chutes that load a belt conveyor. Arc gates in the chutes are operated intermittently by the attendant. The belt is 24 in. wide and travels 50 ft. per minute. This slow speed is desirable on account of the large chunks of ore to be carried, and it also makes it possible to remove pieces of wood, or to sort high-grade and waste.

The conveyor discharges into a 20 by 10 m. Colorado Iron Works Blake crusher set 14 in., which in turn discharges on an 18 in. belt conveyor delivering the crushed ore to the fine-ore bin. This arrangement was chosen, instead of the simpler one of using but one conveyor and

placing the crusher on the bin, to secure a solid foundation for the crusher. It necessitated the digging of a deep pit for the tail-end of conveyor No. 2, but was well justified by the smooth running of the crusher. Another advantage, of no small importance, is that the drip of lubricating oil and grease from the crusher could not

get into the bin and mix with the ore to cause trouble later in the flotation department.

Power for the crusher-plant is furnished by a 25-hp. motor driving a counter-shaft from which the crusher and conveyor No. 2 are driven. Conveyor No. 1 is driven by a chain drive from the tail-shaft of conveyor No. 2. The fine-ore bin has a sloping bottom and holds 100 tons. A belt feeder is used to draw the ore from the bin and the rate of speed is controlled by the spacing of the

**TANK GRADE****MILL BIN****TRAMWAY TRESTLE****THICKENER FLOAT****LOWER END OF MILL****STODDARD MILL**

adjustable skirt-boards. This discharges into the feeder of a No. 64½ Marcy ball-mill. A 6 by 22-ft. Dorr duplex classifier is arranged in closed circuit with the mill, the slime-overflow going direct to the flotation department. The flotation oils are added to the oversize from the classifier, a feeder consisting of several flat-faced pulleys with adjustable scrapers being used for this purpose.

A 100-hp. motor is belted direct to the pinion-shaft of the ball-mill. A counter-shaft driven by a pulley on the extended pinion-shaft provides power for the classifier, belt-feeder, and also drives the 'table' counter-shaft on a lower floor.

The flotation equipment consists of a 16-box rougher-cell and a 6-box cleaner-cell of the Inspiration type. Briefly, these cells consist of a long steel tank having transverse partitions that divide them into the required number of boxes. Each partition has an adjustable gate at the bottom to permit and control the continuous flow of pulp through the cell. On one side adjustable overflow-lips regulate the height of discharge into the concentrate-launder. A removable air-distributor consisting of a cast-iron frame and grid holding a filter fabric is placed in the bottom of each box and connected to the air-header by a pipe running up through the centre of the box.

The rougher-concentrate is elevated by a diaphragm-pump to the feed-box of the cleaner-cell and a second diaphragm-pump returns the tailing from the cleaner to the rougher. These simple little pumps were installed as an experiment, but they performed in such a satisfactory manner that they were retained. The tailing from the

**OLIVER FILTER****JAW CRUSHER****CRUSHING PLANT****DORR THICKENER****MARCY MILL****FLOTATION CELLS**

rougher is sent to three Deister Machine Co.'s double-deck sand-tables, without any attempt to classify, the fineness of the pulp making it unnecessary and impracticable.

Two Dorr thickeners in 8 by 30-ft. redwood tanks are used to thicken the concentrate, one being reserved for each of the two mines. The tanks were spread apart to permit a blower and pump-room being placed between them. A No. 2 Root blower, furnishing air for the flotation cells and the filters, is placed here, also the vacuum-pump for the filters.

A 25-hp. motor drives a counter-shaft carried on concrete piers, from which power is taken for the blower, vacuum-pump, filter counter-shaft, thickener counter-shaft, and the centrifugal pump used in connection with the dry-vacuum system.

Two Oliver 5-ft. filters are placed in a room below this level. Each of these discharges its cake into a deep wide chute having two rack-and-pinion gates at the end. These chutes will hold about 17 tons each, and are in effect storage-bins. The lower end is high enough above the roadway to load directly into motor-trucks, which are used to haul concentrate to the railroad.

Sand and gravel for concrete was hauled in wagons from the river three-quarters of a mile distant, and stored in piles at the foot of the grade. From here it was later distributed by burros as required. All other building material and equipment was brought from Mayer over an old wagon road.

Timber was used entirely in the construction of the bins, tramway-trestle, and building, most of it being second-hand lumber from the San Francisco exposition. In order to minimize the fire-risk a number of plugs, each with its hose and reel, were placed at suitable points outside the mill.

All machinery is set on concrete foundations and provided with ample runways and operating platforms. In all cases the convenience and safety of the operators were regarded as being of the greatest importance.

Water for the mill is obtained from a well in the bed of the Agua Fria river, 3000 ft. distant, and is pumped by an Aldrich triplex pump to a 50,000 gal. mill-supply tank.

Electric power is obtained from the Arizona Power Co., a transformer station near the mill reducing the voltage to 110. With the incentive of a high price for copper, the construction work was rushed at top speed, and the mill was built in three months, being put in operation on August 15, 1916.

ARRANGEMENTS have just been completed at New York whereby the resources of the Engineering Foundation, under the auspices of the four principal national engineering societies, are placed at the disposal of the National Research Council, which was appointed by the National Academy of Science at the request of President Wilson. The object of the council is to coordinate the scientific research work of the country in order to secure efficiency in the solution of the problems of war and peace. The council was without funds until the Engi-

neering Foundation, established to further scientific and engineering research, offered to place its resources at the council's disposal, including the services of its secretary, Dr. Cary T. Hutchinson, to act as secretary of the council. The offer was accepted and plans for immediate activities have been placed in the hands of an executive committee.

Mine-Pumping

Mine-pumping is divided into two general classes, sinking and station-pumping. Station-pumping offers about the same problems as any pressure-pumping for efficient operation, having practically clear water. Occasionally there is the added difficulty of bad water, particularly in mines containing acidic water, where special equipment, brass-lined, must be provided for durability. The same is true of sulphurous waters in the oilfields, which will corrode and pit iron parts much like salt water, in a short time.

In mine-sinking, however, the greatest difficulties arise and each shaft is an individual problem. There must be taken into account the angle of incline, if any; the amount of the in-flow of water; the sharpness of the grit due to blasting; the kind of power available; the desirability of a pump that will "hold suction" well, for keeping the water completely down, and finally, the ultimate reliability of the plant to keep the shaft from being flooded. Then if more economical operation can be secured, a double advantage has been gained.

The steam-pump has been the sinking-pump most commonly used, so that its operation and construction are well understood by mine-mechanics. It can be used under most favorable circumstances, and is reliable. On the other hand, it has many limitations and disadvantages. It must be operated by either steam or compressed air; it has to start the column of water in the discharge at each pump-stroke, involving a heavy loss of power; and it exhausts the steam at full boiler-pressure, another loss.

Pumps of the centrifugal and rotary types are sometimes used, but their limitations are so great as to offset their advantages and render them less efficient and less dependable for practical sinking purposes. They hold suction poorly and are not flexible, requiring practically a fixed speed at all times and different speeds at different pressures, also increased speed to offset wear.

The continuous-acting plunger-pump is flexible, and can be run economically at any speed between say 25 to 100 ft. of piston-speed per minute, and changed as the shaft is deepened, as required. It can be started from the top of the ground without descending into the shaft, and will work equally well when submerged and can be re-packed in about five minutes, making such a type of sinker a most desirable one for mine-managers.—*Mining and Oil Bulletin.*

MANGANESE imports from India during the second quarter of 1916 amounted to 12,326 tons.

Block Method of Top-Slicing at Miami

By E. G. Deane

*A method of top-slicing has been devised at the Miami Copper Co.'s mine at Miami, Arizona, that differs radically in some ways from the customary methods.

The area of the orebody in which top-slicing is used is about 800 ft. square. The ore, while for the most part soft, is, nevertheless, considerably harder than the capping. The latter is silicious, seldom containing any clay or other binding material, and breaks into fine particles so it runs like sand if given the opportunity. Because of these facts, and because the ore is above the average grade of the mine, it has been mined by top-slicing.

Haulage-levels are opened 150 ft. apart, vertically, with two sub-levels between at 50-ft. intervals, to facilitate the building of chutes. These sub-levels are used during slicing for distributing air in the ventilation system. On the haulage-level the drifts are spaced on 50-ft. centres, and raises along these drifts are also spaced on 50-ft. centres, except the incline raises as hereafter noted. The raises are cribbed where necessary. Where the wear will be excessive, $\frac{1}{4}$ -in. iron plates are spiked to the top of every third set of cribbing.

When top-slicing was first used, an attempt was made to carry a slicing-face from fifty to several hundred feet long. Timber and other supplies were brought in through long drifts from an auxiliary shaft. Great difficulty was experienced in keeping these drifts open, the side pressure breaking the posts and the top weight breaking both caps and posts. Furthermore, the men could not work efficiently while these drifts were being repaired. The slicing-faces advanced irregularly, and in many ways the results were not all that could be desired. It was then decided to divide the slicing-area into blocks 200 ft. square and this was later changed to 250 ft. square.

At the centre of each block a two-compartment raise is put up as a supply-raise, the compartment being 2 ft. 6 in. and 4 ft. by 4 ft. 4 in., the smaller used as a man-way. Station sets of 12 by 12 timber with 9 or 10-ft. posts are put in and an ingersoll stretcher-bar air-hoist is mounted above the larger raise-compartment to use in

hoisting the timber and steel. Four bulkheads, built solidly of blocks of square timber, are inserted as shown in Fig. 1. Two of these are 7 by 11 ft. in size, and the other two 7 by 7 ft.

Two drifts, usually untimbered at first, are run out 100 ft. on the long axis of the supply-raise. At the end of each of these and at right angles to them, two drifts are driven 125 ft. to the limits of the block. When these

FIG. 1. TO 4. PLAN SHOWING PROGRESSIVE STEPS IN BLOCK METHOD OF TOP-SLICING.

limits are reached, slices are started toward the corners. These slices are timbered either with single sets consisting of two 8-ft. posts and a 12-ft. cap, or with a double set consisting of three 8-ft. posts and two 7-ft. caps, depending upon the ground. The ore is taken to the floor above.

As soon as the first slices have advanced a few feet, second and third slices are started, and also first slices toward the centres of the block limits. Every man who can work to advantage is used and the ore mined with the greatest possible speed.

Where there is a sufficient mat of old timbers in the back to obviate the danger of the capping running into the ore there is no permanent floor laid, the planks used

*Excerpt from paper presented at Arizona meeting of American Institute of Mining Engineers (September 1916).

in shoveling and wheeling the ore being taken up later. Where there is no mat or it is not sufficient, a floor of 2-in. plank spiked to 2 by 10 sills is laid. Formerly 5 by 10 and 4 by 8 sills were used, but it was found that after being subjected to the pressure and heat of a completed stope, a 5 by 10 or 4 by 8 sill seemed to have no more strength than a 2 by 10.

As soon as the timbers in the slices show signs of taking weight, bulkheads are built of old timbers, obtained either from the mat in the back, or from repair-work in other parts of the mine. As soon as possible, the posts are drilled and the slices shot-down.

By the time slicing has started, four drifts have been run to the centres of the sides of the blocks as shown in Fig. 2 and slicing is also done from these. Working as intensively as possible, all ore except the four central pillars is quickly mined-out as shown in the series of illustrations. When the last of this ore is being taken, cross-cuts are driven to incline-raises, put up to about the centre of the four central pillars, as shown in Fig. 3, and slicing continues, working from the outside of the remaining ore to the supply-raise bulkheads first built as shown in Fig. 1, thus completing the stope. By this time, these bulkheads, which are 10 ft. high when put in, have squeezed to from 4 to 6 ft. in height. Upon completion, the stope is shot-down and another may then be started below, though it is best to let the ground settle for a few weeks.

At first thought the criticism suggests itself that this mining method increases the weight overhead as the block approaches completion. But experience has shown that, as a rule, the maximum weight is taken by the timbers at about the time the outside pillars are completed, and as mining progresses a larger proportion of the weight is taken by the bulkheads in the outside slices. At no time does the weight on the remaining ore and the slices still necessarily open get beyond control. These central pillars constitute our cheapest ore, not only because of the pillar raises but because the ground has been fractured by the weight, and 'lifters' are the only holes necessary to break the face.

All drilling is done with plugger-machines, using a water-spray attached to a 5-gal. can. No cars are used in the slices, all ore being shoveled directly into the chutes or wheeled in barrows. Round timber is used almost exclusively in the stopes, because of its superior strength.

Ten feet has been taken as the standard height of a slice. If a greater height is taken the ore breaks from the top of the slicing face faster than it can be removed and the bottom blasted, thus shortly caving the slice. It is possible that later, when a good mat has been formed, sub-level caving may be used but so far, where tried, it has not been successful.

The ventilation of these slice blocks is important because without it, the heat coming out of the mat is excessive and prevents efficient work. It is accomplished by connecting one of the sub-levels below the slicing floor with the discharge end of a 10,000 cu. ft. fan

Openings are maintained from the sub-level to raises through which it is desired to force air.

As a result of the change to the block method of slicing, and to using forced ventilation, the production per shoveler-shift has been raised from 9 to 20 tons, the production per man-shift from 5 to 10 tons.

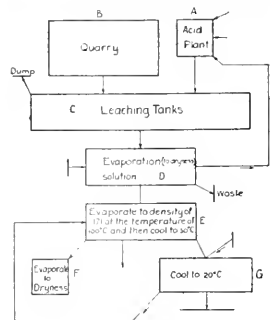

While the details of this method have been fully worked out and a large tonnage of ore has already been extracted by its use, the work to date has to a large extent been preparatory to systematic work for lower lifts. It is not possible to give representative costs, but the following is an estimate of what is expected:

Preliminary development	\$0.035
Haulage development	0.025
Other development (raises, etc.)	0.080
Total development	\$0.140
Stope costs:	
Miners, at \$3.75	\$0.080
Muckers, at \$3.75	0.160
Drills	0.030
Explosives	0.040
Timbering, labor	0.070
Timbering, supplies	0.130
General—bosses, nippers, etc.	0.040
Total stoping	\$0.550
Haulage	0.055
Hoisting	0.040
Pumping	0.005
General underground	0.025
Ventilation	0.015
Engineering and sampling	0.016
Underground lighting	0.004
Mine surface	0.030
Total	\$0.880

OZOKERITE is a mineral wax consisting of a mixture of hydrocarbons, the definite composition of which is not known. In color it varies from black or dark brown to light yellow, but some specimens have a greenish color. It varies from a soft plastic mass to the hardness of gypsum. The melting point ranges from 58 to 80° C. It is valuable for its refined product ceresin which is odorless. Ozokerite is soluble in ether, petroleum, benzene, turpentine, and carbon-bisulphide. Alkalies and the strongest acids have no effect upon it, which makes it valuable for lining vats in which acids are held or used in treatments. In addition to resisting the acids it is unequalled for water-proofing. The list of its uses is a long one, but its most important use is probably in the manufacture of electrical articles. Being an excellent non conductor it finds wide use for the insulation of electric wires and in the manufacture of insulators. It occurs as lenses or fillings of small fissures varying from the thickness of a mere film to veins several feet in width. Extraction from the gangue is simple, requiring a small amount of heat to melt the wax which can then be easily removed. Until recent years the chief supply came from Austria, but since the War, interest has been stimulated in the deposits of this country which are being profitably exploited.

RECENT PATENTS

1,182,668. PROCESS FOR TREATING ROCK CONTAINING ALKALI METALS. Frédéric Ludwig Firebaugh, Berkeley, Cal. Filed April 30, 1915. Serial No. 24,882.

1. The process of treating rock containing sodium and potassium which consists in leaching the rock with sulfuric acid, evaporating the resulting solution to dryness, continuing to heat the evaporated mass to decompose the non-alkali sulfates, adding water to the so-heated mass to dissolve the sodium and potassium sulfates, then concentrating the so-formed solution of sodium and potassium sulfates by evaporation, then cooling the concentrated solution to separate by crystallization the maximum amount of potassium sulfate from the sodium sulfate, then adding to the remaining solution more water and cooling the same, so that the sodium sulfate can be separated by crystallization without crystallizing the potassium sulfate present.

1,194,438. PROCESS FOR SEPARATING METALS. Royal H. Stevens, Salt Lake City, Utah, assignor to United States Smelting, Refining & Mining Company, Portland, Me., a Corporation of Maine. Filed Nov. 20, 1912. Serial No. 732,402.

1. The process of separating metals from ores and like material containing cadmium, bismuth, copper, lead, tellurium, arsenic and similar metals consisting in oxidizing the ore and dissolving in sulfuric acid, electrolyzing the resulting sulfates at a low voltage to separate bismuth and copper therefrom, electrolyzing the solution remaining from the first electrolytic

bath at a different voltage to deposit a cadmium residue therefrom, fluxing and melting said residue to separate tellurium, casting the bullion resulting from the reduced residue, electrolyzing the bullion in a cadmium electrolyte to separate pure cadmium, separating and melting the cadmium sludge resulting from the bullion electrolysis, and casting into plates, re-electrolyzing the cadmium sludge plates in a cadmium electrolyte to abstract pure cadmium, separating and melting the bismuth residue from the cadmium bullion electrolysis, and casting into plates, electrolyzing the bismuth residue plates in a bismuth electrolyte to separate pure bismuth from a copper, lead and cadmium residue.

1,185,129. CONCENTRATOR. Charles F. Paige, Oakland, Cal., assignor of one-third to Adolph W. Jones and one-sixth to Harry B. De Mooy, Oakland, Cal. Filed July 8, 1915. Serial No. 38,701.

1. In a concentrator, a table, a flow surface formed on the table over which the pulp is adapted to travel, means for shaking the table to cause the pulp to travel in a certain direction, a cover section having a plurality of discharge openings formed therein inclosing the flow surface of the table, and a skimming plate secured to the cover section adjacent to each discharge opening to carry the light material up through the opening and up over the top of the cover.

1,195,453. ORE-CONCENTRATOR. William Fagergren, Salt Lake City, Utah, and William D. Green, Butte, Mont., assignors, by mesne assignments, to Metals Recovery Company, a Corporation of Maine. Filed Aug. 12, 1913. Serial No. 784,336.

1. In an ore concentrator, the combination of a tank, a receptacle located within said tank and provided with a wall having a continuous edge from which ore materials may be discharged, means for introducing within said tank and within said vessel ore pulp or the like, means for admitting air into said receptacle, a dasher located within said receptacle for the purpose of agitating said ore pulp and said air, a plurality of baffle floors located at different successive levels within said tank and provided with openings, and means for discharging gangue and water overflowing from said receptacle within said tank and means for discharging concentrates from the top of said tank.

1,197,589. PROCESS OF TREATING ORES. Raymond F. Bacon, Pittsburg, Pa., assignor, by mesne assignments, to Metals

Recovery Company, a Corporation of Maine. Filed June 28, 1915. Serial No. 36,638.

1. The method of effecting the separation of non-sulfid ores from associated gangue, which comprises subjecting the mixture, in a finely divided condition, to the action of hydrogen sulfid in the presence of sulfur dioxide and thereby converting the metal values into sulfids and forming colloidal sulfur within the mixture, and subjecting the resulting mixture to a flotation treatment; substantially as described.

1,195,616. METHOD OF EXTRACTING METALS FROM THEIR ORES. Henry B. Slater, Riverside, Cal. Filed Sept. 2, 1913. Serial No. 787,598.

1. The method of extracting copper from its ores which consists in subjecting the ore to the action of a solution containing alkali metal chlorid, and a metallic chlorid capable of reduction to a lower chlorid, together with hypochlorous acid, then precipitating the copper from the solution, and then subjecting the solution to the action of free chlorine in the presence of a metallic hydroxid to regenerate the solution containing hypochlorous acid together with a metallic chlorid capable of reduction to a lower chlorid for use in a cyclic manner.

1,196,917. PROCESS OF AND APPARATUS FOR SIZING OR CLASSIFYING COMMINUED MATERIAL. Henry M. Sutton, Walter L. Steele, and Edwin G. Steele, Dallas, Tex. Filed Feb. 5, 1914. Serial No. 816,754.

1. The process of sizing material, consisting in transporting material composed of grains of varying size, on a series of successive supports, inclined transversely to the direction of transporting movement, and subjecting said material to gravitative impulses adapted to deviate the components of said material from the direction of transport in proportion to their respective size, progressively varying said gravitative impulses upon the successive supporting surface, and separately collecting the separated size of material from the last supporting surface.

1,198,611. METHOD OF EXTRACTING PRECIOUS METALS FROM THEIR ORES. Thomas R. Cowe, Axtel, Colo. Assignor to

The Portland Gold Mining Company, Colorado Springs, Colo., a Corporation of Wyoming. Filed Mar. 2, 1915. Serial No. 11,603.

1. A method of extracting precious metals from their ores, which consists in placing finely ground ore in a cyanid solution, blowing into the mixture under pressure a constantly renewed supply of fresh atmospheric air, while maintaining the mixture under a pressure greater than atmospheric pressure.

2. A method of extracting precious metals from their ores, which consists in placing finely ground ore in a cyanid solution, blowing a constantly renewed supply of fresh atmospheric air into a mixture, and restricting the escape of said air, so that the mixture is maintained under pressure greater than the atmosphere.

1,191,949. FILTER. Charles D. Burchenal, New York, N. Y. Filed Mar. 10, 1916. Serial No. 83,280.

1. A filter, comprising alternating cells and plates and filtering mediums between them, the cells and plates being provided with a longitudinal supply passage opening into all the cells, and the cells and plates being provided at opposite sides with longitudinal outlet passages, each plate being connected at one face with the outlet passage on one side of the filter and each plate having its other face connected with the outlet passage on the other side of the filter.

1,198,086. PROCESS OF EXTRACTING PRECIOUS METALS FROM THEIR ORES. Albert E. Vandercook, Alameda, Cal., assignor of one-half to Leslie B. McMurtry, San Francisco, Cal. Filed Oct. 21, 1911. Serial No. 868,159.

1. The process of recovering precious metals from a mixture of sulfid ore and metallic particles with a sodium or potassium cyanid solution, which consists in agitating the mixture in the presence of mercury whereby a double cyanid of mercury and sodium or potassium is formed which removes the alkali from the solution.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MEXICO CITY, MEXICO

ABSTRACTS OF RECENT DECREES AND COMMENTS THEREON.

During the summer two important decrees for the mining industry were promulgated by Carranza. The first was drafted on May 1, but part did not go into effect until July 1; it concerns taxation. The second decree began to operate on August 15, and affects the property rights of foreigners. A condensed translation of the first or taxation decree reads as follows:

PERMANENT ARTICLES. ARTICLE 1. There still remain subject to the Stamp Tax all metals for export, whether originally produced at home or abroad. This tax will be levied as follows:

A. On metals that are exported in the form of mineral or earth, cyanides or sulphides, smelting residue, or in any other form in which they are mixed with non-metallic substances, as follows: Gold and silver, at rate of 10% *ad valorem*, other metals at rate of 5% *ad valorem*. The Secretary of the Hacienda (Treasury) will fix each month the values of the metals for taxation from the quotations in foreign markets.

B. On metals that are reduced to pure metals or alloys at home the above rate will be lessened by 20%, whatever the assay of the product.

ARTICLE 2. There will be no Stamp Tax levied on the following:

A. Refined gold, which is brought to the mints for coinage, and which is presented at the Federal offices in exchange for silver money at the rate of 75 centigrams of pure gold for one peso, (P1).

B. Current gold or silver coins, whether native or foreign.

C. Silver that is exported in products not exceeding a content of 250 grams per ton. Such products may be in the form of lumps, earthen, or powders; and may be in their natural state, or as concentrates, sulphides, cyanides, or smelting residues.

D. Silver and gold imported in any of the forms of the last paragraph, or partly refined, which may be exported within the four following months in cakes, ingots, or bars, after having been subjected to metallurgical treatment in Mexican works.

E. Gold and silver which is used in national industries.

F. Samples of natural minerals that are exported according to administrative regulations.

G. Ores of copper with less than 3% copper; ores of lead with less than 10% lead; and ores of zinc with less than 15% zinc.

ARTICLE 3. Assay-fees will only be charged for assays made at the request of those interested, by legal rule, or by administrative order; smelting fees only when a lack of homogeneity of the bars or pieces requires smelting for a proper valuation; and refining and parting-fees only when such operations are performed in Government offices at the request of the interested parties. The fees just mentioned will be fixed according to the cost of the operations, and from a schedule issued by the Department of Hacienda.

ARTICLE 4. Metallurgical enterprises will still be subject to the common Treasury regulations in all their operations.

ARTICLE 5. The special stamps that existing laws require for the titles of mining property will be at the rate of P10 Mexican

gold for each pertenencia (1 pertenencia = 2.47 acres) titled, irrespective of the kind of mineral denounced.

ARTICLE 6. The annual tax-rates for mineral land will be:

For gold and silver lands: for 1 to 10 pertenencias at the rate of P6 each; 11 to 50, P12; 51 to 100, P18; and 101 or more, P24 each.

For other mineral lands: for 1 to 50 pertenencias, P6; 51 to 200, P12; 201 to 500, P18; 501 or more, P24 each.

ARTICLE 7. The graduation of the rates will apply when the pertenencias belong to one owner and lie in the same mining district.

ARTICLE 8. The States will not assess mining at more than 2% of the gross mineral output, and will except ores of iron and quicksilver.

ARTICLE 9. There will be no import tax on the following substances, when they are imported for treating ores: zinc, whether in bars, filings, grains, shavings, or small sheets; sulphur, alkaline cyanides, sodium hyposulphite, and nitrates of potash or soda.

ARTICLE 10. All sums due the Exchequer under this decree must be paid in national gold coin.

TEMPORARY ARTICLES. ARTICLE 1. This decree will begin to apply at once, excepting the rates fixed in Article 6, which start only on July 1, 1916.

ARTICLE 2. Hereby are annulled the decrees of March 25, 1905; of March 1, 1915; the articles No. 2, 4, 10, 11, and 12 of the decree of March 27, 1907; and any remaining rulings that may be opposed to this decree.

ARTICLE 3. Any owners who owe taxes on mineral pertenencias will settle them as follows in gold:

A. Debts previous to March 1, 1915, will be settled at the then prevailing rates plus 200% of penalty.

B. Debts covering the four months from March 1 to June 30 of 1915 will be settled at the rate of P6 per pertenencia annually for the first 25 and at the rate of P3 each for the excess above 25 pertenencias, all plus 100% of penalty.

C. Debts covering the four months from July 1, 1915, to October 30, 1915, will be settled at the rate of P6 annually per pertenencia, whatever the number, plus 50% of penalty.

D. Debts covering the four months from November 1, 1915, to February 29, 1916, will be settled at the rate of P8 annually per pertenencia, plus 25% of penalty.

E. Debts covering the four months from March 1 to June 30, 1916, will be settled at the rates of the decree of March 1, 1915, with no penalty.

ARTICLE 4. Hereby is granted a non-extensible period, ending June 30, 1916, in order to pay the annual taxes due until February 29, 1916; a failure to pay will mean *caducidad* (annulment of title).

ARTICLE 5. For once only and solely for the debts due until February 29, 1916, there is allowed the option of payment either in gold or in its equivalent in credit money at the rate fixed by the Monetary Commission.

ARTICLE 6. Any debtors who, previous to March 1, 1915, may have paid any sums beyond those prescribed in these transitory articles, may have such excesses credited on subsequent payments.

ARTICLE 7. The tax of 5% on base metals, mentioned in A of ARTICLE 1, will apply to copper when its New York cash price

is less than 25c. per pound. When its price is between 25 and 30c. the tax will be 6%, and when beyond 30c., 7%.

ARTICLE 8. The gold and silver products which, without leaving the country, may have satisfied the Stamp Tax of the decree of March 1, 1915, will pay when they are exported the quantity still lacking to cover the rates fixed by this decree.

CONSTITUTION AND REFORMS. Given in the National Palace, Mexico City, May 1, 1916, by V. Carranza, First Chief of the Constitutionalist Army, to Luis Cabrera, Secretary of State and of the Hacienda.

The second, or foreigners' decree reads as follows:

PREAMBLE. Considering that our basic laws give to strangers the same rights as Mexicans, it is natural and lawful that the former also assume the same obligations, for the liberality of our democratic institutions should not reach the extreme of giving to foreigners, owning property here, a better judicial position than Mexicans, as has hitherto sadly been the case. This would happen if foreigners, besides enjoying the rights granted by Mexican laws, should be allowed to plead and make complaints to their respective home governments. The First Chief of the Republic has therefore used his extraordinary powers in order to establish the following decree throughout Mexico:

ARTICLE 1. Any foreigner who wishes to acquire in Mexico public lands, mining claims, Federal waters, or permits for the exploration or exploitation of natural resources, such as forests, petroleum, fisheries, etc., must present a written renouncement to the Secretary of Foreign Relations. This document must make a formal and final declaration that, as an owner or concessionaire, and for all the effects and relations of the property to be acquired, the foreigner must renounce all his rights as such to ask protection from or complain to his home government. Foreign companies are also incompetent to acquire rights over the class of property mentioned in this circular, until they submit to Mexican laws and make the above renouncement.

ARTICLE 2. It will be an indispensable pre-requisite before the Secretary of Fomento can accept any denouncement or petition about this class of property, however trivial, that the foreigner present at the beginning a certificate from the Secretary of Foreign Relations showing that he has made the above renouncement. Lacking this certificate the petition will be rejected and will have no legal force no matter how much it may be agitated.

In all titles and permits delivered by the Department of Fomento and in all contracts or public documents before a notary concerning this class of property, a clause certifying the above renouncement must be inserted or the writing will be legally void.

ARTICLE 3. In all applications already made by foreigners, which are now in transmission before the Department of Fomento or its branches, concerning this class of property, the transmission will be suspended immediately and will not be resumed until the presentation of the above certificate of renouncement. If this last is not presented within the space of four months from the date of this decree, the petition will be deemed abandoned, and the attendant applications will be filed without allowing the interested party any right of further appeal.

Constitution and Reform. Mexico City, August 1, 1916. The Under-Secretary of the Department of Fomento, Pastor Rojas.

This decree, connected with the one described in my letter of June 19 and July 15, is contained in number 1. The really important new item in this decree is the export and output tax on metals, a tax on mineral income, and a renouncement of diplomatic protection. Under this the export tax is fixed at 2%, not only on 99% of the metal, while the output tax on all metals was at 1% for the State

plus 1% for the Federation. The new rates thus mean nearly a tripling of the old schedule, though this is not due all to Carranza, as Huerta in 1914 raised the tax on gold to 10%. These bullion taxes, of course, affect only the few mines in operation, and all but the poorest of these can probably afford to pay them, owing to the high price of all metals except gold. Under Huerta the great gold mines at El Oro were able to support the 10% bullion tax, and can therefore do so now, provided they can get adequate protection from bandits, and regular railroad service. However, a tax on the gross output is not a fair tax—only a tax on net profits can be that—and the more the rate is advanced the more onerous becomes the burden on low-grade mines.

A mistaken view seems to prevail in the United States regarding the new taxation of mineral land, which policy is indeed one of the few genuine reforms inaugurated by the Carranza party. The Diaz rates of ₧6 (Mex.) per pertenencia up to 25, were grossly inadequate as a defense against forestalling, as they were equivalent to only \$1.20 U. S. and 60c. per acre respectively. The ancient Mexican policy of requiring continuous work, as the requisite to holding mines, was finally abandoned in 1892, and replaced by a land tax which was so trivial as to put the 'land hogs' into clover.

By 1910 there was perhaps not a district in Mexico where a prospector could find any ground unoccupied that had mineral possibilities. It was common then for great companies or rich individuals to hold 1000 to 5000 acres of mineral land in one district while seldom working 5% of their holdings. Wherever Carranza can protect the operator properly, the new rates are none too high to discourage forestalling—that curse of the United States mining industry also. Where the prevailing anarchy makes production impossible, there and there only has the land-holder just cause for complaint at the new policy of taxation.

The decree of renouncement may be looked at from two view-points: The preamble is certainly plausible in claiming that Mexicans should enjoy the same right to the use of their own natural resources as do foreigners. However, the right of diplomatic intervention could hardly mean more than securing justice for the foreigner according to Mexican law and in view of the rotten condition of the Mexican courts for generations, a foreigner can hardly be blamed for wishing all the guarantees possible. Whatever Carranza's object in requiring renouncement, whether it be merely a sop to placate his anti-foreign following or a step toward complete exclusion of foreign enterprises, it seems certainly an inopportune time to issue such a decree. If Carranza really means to comply with his treaty obligations and to treat foreigners fairly, the decree seems entirely unnecessary. It is likely that Carranza will find his decree a boomerang that will merely strike another blow at the decrepit structure of 'Constitutionalism,' for which his party claims to stand sponsor, and which was nearly wrecked by the dreadful financial decrees of last June.

The fact that the decree of August 15 was followed within a month by the decree of September 15* offers little hope to foreigners as to the benevolence of the only protector they will have remaining after a renouncement of their own diplomat. The provisions of the September decree leave a mine-owner at the mercy of the bureaucrats of the Department of Fomento, these may prescribe as they choose concerning the minimum number of men to be worked 'continuously' on his property. Even when bandits and lack of transport render any operation impossible, the mine-owner will still forfeit his mine automatically unless he has the luck to get from the bureaucrats a permit to excuse his inactivity. In view of the anarchy prevailing throughout Mexico, this decree will give Carranza a goodly opportunity to confiscate 90% of foreign-owned mines before this end—should he choose to do so, even supposing the

*M. & S. P. Oct. 7, 1916, p. 537.

decree is carried out with all due respect to legitimate interests, yet the gross ignorance of the Fomento bureaucrats regarding practical mining would render it an unmitigated nuisance to all operators and a ruinous burden to not a few.

In this connection it is interesting to mention the program of the anti-foreign party so charmingly portrayed by Lic. Andres Mollino Enriquez in his 'Problemas Nacionales.' As this book was published during the regime of the capital-hunting Diaz, it could not detail the scheme as it affected the property of foreigners, but merely gave what it proposed regarding their persons. First, all immigration of laborers was to be forbidden; next, foreign factory-foremen would be admitted only for a long enough stay to instruct Mexican successors in their duties; and finally, no foreign doctor, engineer, or other intellectual could practise his profession in Mexico until he had taken out citizenship papers.

Enriquez' frankly-expressed plan is to make Mexico a close preserve for the benefit of the existing Spanish-Indian mestizos, the pure Indians to be assimilated by inter-marriage. His original following consisted of middle-class youths inspired by an insane jealousy and prejudice against their foreign rivals for employment, not realizing that their own irresponsibility, dishonesty, and medieval education made them unworthy of anything but inferior positions with foreign companies. In fact, nearly all big business, such as manufacturing, mining, and wholesaling, has always been in foreign hands owing to the inefficiency of the native middle-class. During the revolution the anti-foreign faction has, for the first time, been allowed to extend its propaganda freely among the town-artisans and the armies, until finally a complete control of the Carranza government apparently has been achieved.

The fact that so many Carranza generals and politicians have made revolution a business and risen from poverty to affluence since 1912 is of sinister import to foreigners, for such keen appetite for loot will never be finally appeased until it has fed freely on the two billions of foreign-owned property. But the same fact militates against the plans of the Magon anarchistic propaganda, explained in *Regeneration* of Los Angeles (see my letter of January 29), which proposes to take over all property in Mexico, whether native or foreign, and administer the country as a communistic state for the benefit the peons. The suppression of the Magon propaganda, as exemplified by the orators of the I. W. W. of Mexico City last February, showed the difference in ideals between the Carranza ring and Magon. Evidently only those "practical" from long experience in Carranzista interventions will take charge of all the foreign property to be confiscated in the future as they have done of the reactionary property in the past, and idealistic dreamers of the Magon type will be given nothing for their peon followers except some decree forbidding immigration.

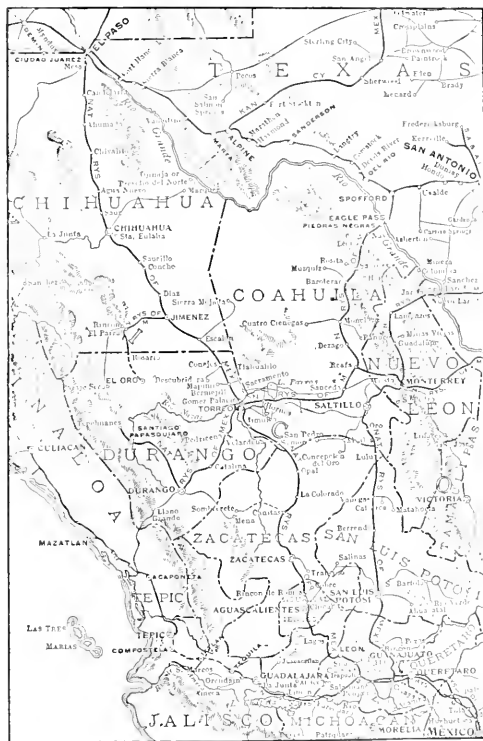

MAZATLAN, MEXICO

CONDITIONS IN THE WEST COAST DISTRICTS.

Train service has been resumed between Mazatlan and Nogales on an irregular schedule. The trip now requires four days where formerly it was made in a day and a half. Trains run only during the day-time owing to the bad condition of the road-bed, which makes night-travel exceedingly dangerous. Nearly all of the work expended on the railroad during the last four years by the various 'istas' has been in destruction rather than construction. Heavy rains of the past few months have washed away a number of the flimsy wooden bridges that had replaced the substantial concrete and steel structures long since made useless by the different factions in their military movements.

Most of the Americans who abandoned their properties last June have returned and are working their mines. The prin-

cipal mines at work in this district are the Potrero Mining Co., at Potrero, the Guadalupe de los Reyes, the mines at San Dimas, Durango, and the Minas del Tajo, at Rosario. The famous old Panuco mine, which has been worked by the Carranza government for the past two years, was flooded by the recent rains and has been abandoned. It is said that the de facto Government is willing to return the mine to the owners if they renounce their claims to indemnity. Also that the Government is willing to release the San Jose de Gracia mines

WEST-CENTRAL MEXICO.

to the former owners on the terms that they pay 30% of the gross output. It is impossible to work under such conditions with the guarantees that the present Government can furnish.

The issues of *infalsificable* bills that were to replace all the previous paper-issues have fallen into ill repute and are now exchanged at the rate of thirty to forty for one American dollar. It is surprising the large amount of American money that is in circulation. All transactions of any magnitude are done with the American dollar. Even the poorest peon calculates his values in terms of American money dividing the paper peso by 30 or 40 according to the prevailing rate of exchange. There are rumors from Mexico City of a silver coinage to take place in the near future for the government evidently realizes after this last failure of the *infalsificables* that the people are tired of paper and want a medium of exchange of more purchasing power. Meanwhile Carranza continues to issue decrees, no longer one at a time but in series, while the politicians and military leaders rob the people and prey upon the mining industry.

Fear of starvation due to the scarcity of corn this summer, caused a great amount of the cereal to be planted. There are prospects of a good harvest.

SUTTER CREEK, CALIFORNIA

SPIKE SITUATION AND CLASH AT THE SOUTH EUREKA.

The following notes were written on October 15:

The expected re-opening of the South Eureka and Central Eureka mines here on the 10th was prevented by striking miners gathering, nearly 200 strong, on the road leading to the mines and ordering the men not to work. The Sheriff and a number of deputies were unable to disperse the crowd, and when W. G. Snyder, the district attorney, appeared on the scene, and had the president of the Union explain to the strikers that it was unlawful for them to gather there for the purpose of obstructing the road and that if they did not disperse they were liable to arrest, the warning was received with derisive smiles from the men. Sheriff Layot, on his return to Jackson, notified the Governor's office of his inability to handle the situation, with the result that the State labor commissioner, John P. McLaughlin, and J. J. Kelly, one of his special agents, are now here, endeavoring to bring about an amicable adjustment of the difficulties existing. Union pickets have continued to warn miners, engine-men, and pump-men from working, 15 or 20 men waiting along the road up Sutter hill at times when the men ready to return to work would be going on shift. On Wednesday night about 7 o'clock a number of men obstructed the road when James Kerfoot, one of the Central Eureka engine-men, drove toward the mine in his car, and one of the men, Obron Mijovich, was run over, sustaining injuries from which he died the following morning. Kerfoot proceeded to the mine. Fearing violence to Kerfoot, the Sheriff organized a posse, including a number of armed men from Sutter Creek, Jackson, and Amador City, possibly a hundred in all, and marched up the hill to the mine. The men, some of whom were said to have threatened to avenge the death of their comrade, had all disappeared by the time the citizens under the Sheriff reached the mine; they then accompanied the Sheriff, with Kerfoot, to Jackson. At the inquest on Mijovich's body next day, the witnesses examined were unable to name the man driving the car, although one identified him as a Central Eureka engineer, so the verdict of the Coroner's jury was as follows: "Obron Mijovich's death was due to injuries sustained by being struck by an automobile on the public highway at the hands of an unknown party or parties." Great excitement prevailed during the night and day following the accident, and the deceased miner was yesterday given the largest funeral ever witnessed in Amador county. About 700 Union miners joined the procession, which lends color to the Union's claim that their membership has greatly increased since the strike was declared on the 19th of last month. When the engine-men and pump-men were not permitted to keep the mines unwatered, the South Eureka company threatened to demand reimbursement from the County for damage resulting from a lack of protection. About a dozen men from outside points have been provided for at the South Eureka mine, bedding and provisions for their use having been placed on the ground, but it is understood these men are acting as guards and not as pump men or engineers. The Union has signified its willingness to have the engine-men and pump-men return to work, provided they are only required to keep the mines unwatered, and it is understood that most of the mine-owners have agreed to this arrangement, and desisted from the extensive repairs that has been in progress since the strike began, but the Sutter Creek operators have not yet met the demands of the Union in this regard and work is at a standstill, including pumping at the South and Central Eureka. John Martin and H. Malloch of the South Eureka mine, and V. S. Walsh of the Central Eureka, have been here during the week, and they held a meeting yesterday with other operators, but without definite result, and conjecture is as to what the next move will be.

Up to October 18 there was nothing new to report.

PLATTEVILLE, WISCONSIN

ZINC-ORE CONDITIONS DURING SEPTEMBER.—ORE STOCKS.—NEW

PLANTS.—LEAD, PYRITE, AND CARBONATE CONDITIONS.—PRODUCTION.

During September there were new records in the zinc-lead region, in spite of conditions that tended to retard both development and operation. Prices for zinc ore were at a standstill all the month, the standard 60% product and premium grades holding steadily at \$56 per ton, with the range down to \$50 for concentrate as low as 50% zinc-content. Many prominent operators personally interviewed earnestly declared that the high cost of supplies and labor, both skilled and unskilled, made these prices no more profitable than the \$40 standard, when other conditions were normal. Toward the close of the month fair gains in the price of spelter and a sturdier tone in the market served to influence ore prices, and the range was raised to \$58 per ton for 60% base, and the range down to \$50 was increased to include ores containing no less than 54% metal. The discrimination against producers of low-grade ore for the past three months was thus further emphasized, as it brought ore of this character into still greater disrepute. The result was evident before the month was over, several producers of long standing suspending operations, giving as the reason the low prices for ore; but to be more exact, because there was absolutely no demand for low-grade ore from independent operating mines to zinc-ore refineries well supplied with ore from mines operated in combination with separating plants.

A large reserve of zinc concentrate was on hand in the field at the close of the month, the Highland, Linden, Mifflin, and Platteville districts between them holding 6000 tons. In the other districts and south of Platteville, most of the large mines are owned by foreign corporations, who divert their output to refineries operated in connection with them, and it is here that little ore is carried over at the end of a month. But there are also many independent companies in this part of the field, which accounted for another 1500 tons.

Ideal weather conditions, copious rains at intervals filling mill reservoirs, a return to the mines of many farmers who have garnered their crops and who work in the mines during the winter, good roads, and steady prices contributed to an exceptionally heavy production of ore in September, and shipments of high-grade ore out of the field to smelters were higher than for any single month yet reported.

Decided gains were recorded in the price of lead ore, offerings at the beginning being as low as \$60 to \$65 per ton for 80% base, but the price mounted higher from day to day and closed the month in advance of \$75 per ton. It was thought that this price would bring out most of the ore held, but it failed to do anything of the kind; and producers of lead ore, usually a keen crowd, held onto their ore in hopes of even better prices. It was conservatively estimated that 1500 tons of lead concentrate was on hand at the end of September.

Shipments of iron pyrite increased considerably, although no increases in offerings were admitted. The reserve had grown to such proportions at all the zinc-ore refineries that holders of pyrite were glad to get some of it out of the way, prices concerning them little. There is still held in reserve over 15,000 tons, and no great amount will be worked-off at an early date.

Producers of carbonate of zinc ore received no attention from buyers.

Deliveries of ore during September were as follows: 30,685 tons of ore, 1.5 tons of lead, and 1276 tons of pyrite. These are the highest figures ever attained in this field for deliveries of zinc product. The actual production of crude concentrates was also the highest, being over 25,000 tons; while shipments of high grade ore direct to smelter broke all records with a total of 15,000 tons.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

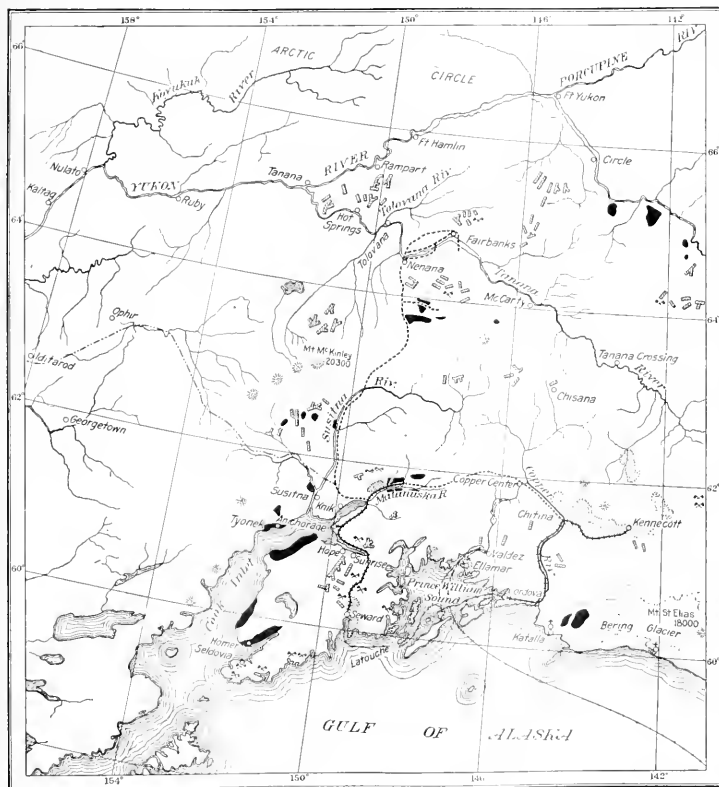

The report of the Alaskan Engineering Commission, with maps, charts, and profiles, covering the period from March 12, 1914, to December 31, 1915, has been issued. One part con-

sists of a foreclosure sale at New York on October 18. The purchasers will then have a clear title to the property. It was thought that the United States Smelting, Refining & Mining Co., which has spent a great deal of money on the mine, would be the buyer.

Commenting on the present situation of the Alaska Gold Mines Co., the *Boston News Bureau* says that it seems to be the settled conviction of those closest to the management, that for several months at least nothing need be expected in the way of operating returns better than those now being reported. During the first 10 days of September the average assay-value of the ore was \$1.51 per ton, but for the entire month the average dropped to \$1.39 per ton, indicating rather poor results for the last 20 days. There is a large accumulation of low-grade ore broken in the upper-level stopes, and this material must be removed and milled—as there is a small profit in the operation—before opportunity is given for opening stopes in the lower levels in a manner which it is believed will yield a larger return per ton of ore treated. Officials of the company are convinced that the original scheme of opening the stopes was a mistake, in that it resulted in an excessive caving of the hanging-wall material, which was low in grade; but as there is over 2,000,000 tons of this low-grade ore already broken in the upper levels, some time must elapse before any new scheme of mining can be put into effect. The new plan of ore extraction will probably involve an additional cost of 5c. per ton. All construction work at the property has been completed. Present indications, however, are that the mine will never be able to treat the expected tonnage of ore that will yield \$1.75 per ton, so that early estimates as to prospective profits must be revised downward.

ARIZONA

Celestite and strontianite, the strontium sulphate and strontium carbonate respectively, are discussed by F. L. Culin, Jr., in Bulletin 35 of the Arizona Bureau of Mines. Strontium salts are used at beet sugar refineries, fireworks, and in medicine. The metal belongs to the same group as calcium and barium. The minerals are found in limestone and gypsum. The demand is small and fluctuating, and high-grade ore receives only \$2.50 to \$4 per ton. In Arizona, 15 miles south of

SOUTH-CENTRAL ALASKA SHOWING RELATION OF RAILWAYS TO MINERAL DEPOSITS.

sists of 216 pages of profusely illustrated data, describing the route of the line now under construction. There are in a separate pocket 18 large maps. A great deal of interesting matter deals with railroad construction and difficulties encountered. Resources and towns of the country tributary to the line are detailed. Alaskan residents should secure a copy of this report.

JUNEAU. Shares of the Ebner Gold Mining Co. were to be

Gila Bend, in Maricopa county, celestite occurs in sedimentary series associated with gypsum, sandstone, and conglomerates.

(Special Correspondence.)—The Desert Power & Water Co. is now within 12 miles of Chloride with its high-tension line. Work is under way from both ends. Two hundred houses are wired.—The Schenectady is putting in a compressor and drills.—Rich copper ore has been found in the Weaver district by George W. Lynch; also on adjoining claims by W. C. Richings and C. E. Southworth.—The Keystone found rich ore on the 399-ft. level. There is nearly 8 ft. of shipping ore on that level.—The Hidden Treasure has just finished installing a compressor and drills. It has 300 ft. more to drive through granite to cut the large vein at a depth of 500 ft. W. B. Twitchell of Ray is one of the principal owners.—Concentrates at the Arizona Butte assay 12 oz. silver, 66% lead, and \$45 gold per ton. The new mill is working perfectly.—Senator Guggenheim is about to take over the Golden Hammer, which has a splendid showing. The adit opened the vein for 100 ft.—Burros are being used to pack an initial shipment of 250 tons from the Black Jack to the railroad here. Ore exceeds \$100 per ton.—The Guggenheims have completed sampling the Payroll, and it is understood that the deal is about closed.—The Georgia Mining Co. has started sinking, and is down 100 ft. Drilling will commence at 300 ft.—Molly Gibson-Chloride is being unwatered and the shaft repaired; likewise the Hercules and Distaff.

Chloride, October 10.

CLIFTON. In *Economic Geology* for August-September, Louis E. Reber, Jr., discusses mineralization in the Clifton-Morenci district. The paper covers 45 pages, and is well illustrated, especially with microphotographs. Most of the ore-minerals occur in disseminated particles or veinlets in porphyry, though usually associated with some larger veins; and the orebodies owe their commercial value to chalcocitization by the process of secondary enrichment. The country rocks are pre-Cambrian granite, Paleozoic and Cretaceous sediments, and the younger Intrusives.

RAY. Reserves of the Ray Hercules mine are now estimated as 10,000,000 tons of 2½% copper ore. At a depth of 675 ft. native copper has been seen in good quantities. The shaft is being deepened at the rate of 5 ft. daily. Three churn-drills are prospecting. A 2000-ton mill has been ordered instead of 1000 tons' capacity as formerly contemplated.

ARKANSAS

YELLVILLE. The output of zinc ore during September was regular, and totaled 80 carloads.

CALIFORNIA

There have been 550 new oil-wells started in California since the first of this year, according to reports made by operators to the State Mining Bureau. The report for the week ended October 7 shows eleven new wells, about equally distributed between the San Joaquin and Southern fields. Eighteen wells were reported ready to test for water shut off, 3 to deepen or re-drill, and 1 abandonment. The first annual report of State oil and gas supervisor, R. P. McLaughlin, covering the last fiscal year, has been compiled for the State Printer and will shortly be ready for distribution. It will contain a financial statement and summary of the work done by the Department, together with a detailed list of all wells passed on. The report explains general methods that must be followed by oil operators in order to protect their lands and extract the maximum amount of oil, special mention being made of the concerns at present following such methods.

The U. S. Geological Survey has issued U. G. Yale's Mines Report of 10 pages on the gold, silver, copper, lead, and zinc output of California during 1915. From 605 mines from which 3,967,779 tons of ore was extracted, the yield was

\$22,442,296 gold, 1,678,756 oz. silver, 40,751,625 lb. copper, 4,579-245 lb. lead, and 13,094,032 lb. of zinc. The total value was \$32,263,841. All totals were considerable gains, while the value was \$6,553,199 more.

ALLEGHANY. There are now 50 stamps crushing ore on Kanaka creek, the 10 head at the El Dorado being the newest.

FORBETOWN. An Italian syndicate is reported to have bought 12 claims lying north-west of the old Gold Bank mine. An adit is to be driven from the south fork of the Feather river to explore the ground.—At the Southern Cross mine, owned by Rosenthal of San Francisco, a flotation test-plant is at work.—The Carlisle mine is being drained in charge of Mr. Miller.—Activity is in progress at the Campbell, Denver, and Forbestown Consolidated mines.

GEORGETOWN. The Georgia Slide mine is to be further developed, and it is proposed to erect a plant to treat a large quantity of hydraulic tailing in Canyon creek.

It is said that the company working the Georgia Slide mine is unwatering the Beebe mine, situated within the town boundary.

JACKSON. The strike will result in a reduction of gold output from Amador county, even compared with 1914, if it lasts much longer. In 1915, 22 mines produced gold worth \$3,903,969 from 819,550 tons of ore, an average of \$4.76 per ton. This was a gain of 188,705 tons and \$812,123 compared with 1914.

KENNETT. The three-mile aerial tram from the Stowell mine to the terminal of the Balaklava mine has been completed by the Mammoth Copper Co. Ore can now be sent from the Stowell to Coram over the tram, then to the smelter at Kennett by rail.

NEVADA CITY. When the Alaska mine opens next spring W. S. Schuyler proposes to drive an adit one mile long, starting on Oregon creek. This work will be cheaper than draining and opening the mine by a shaft.

OAKLEY. The American Girl mine, controlled by wealthy Pasadena people, including Dr. R. Schiffmann, is said to contain large low-grade orebodies, and is extensively developed to a depth of 700 ft. A modern 150-ton mill, after considerable re-modeling, was successfully operating when the mine was flooded by a cloud-burst which ripped the timbers out of the shaft and filled most of the workings with stope-fillings. Shares of the company had already been issued at par, and no less than nine assessments of 10% were then levied in order to again put the mine in shape and continue development. An expensive arrangement was also constructed to prevent a similar occurrence damaging the property. The shareholders do not number more than twenty, and this method of practically doubling the capitalization was met without requiring outside aid. Owing, however, to the mine developing into a large low-grade property requiring extensive further development, no doubt it was considered advisable to sell to Eastern capital or to undertake some drastic scheme of re-financing.

(Special Correspondence.)—The option of W. J. Loring and associates on the Hardenberg mine, situated near the Mokelumne river, 3½ miles south of Jackson, dated from September 1, but work has been delayed on account of the strike in Amador county. The property consists of 41 acres, and covers the lode for a distance of 2129 ft. along its strike. The new vertical shaft is on a "caddle" between two hills, about 1600 ft. above sea-level. The mill is on the hill-side below the shaft collar. It is said that this was one of the first quartz-gold mines to be operated in California. The old mill had stamps with wood steps. In 1893 a shaft was sunk 600 ft. About that year C. D. Dine and Alvinza Hayward took an option on the mine. From April 1894 to 1895 there was treated 2100 tons of 34½% ore. F. G. Martin, manager of the Utica Mining Co. of Angels was then in charge, and attributes the suspension of work to the disinclination of Hayward to spend

more money on the property, being then heavily involved elsewhere. From 1895 to April 1911 the mine was idle, when the Hardenberg Mining Co. took it over. The new vertical shaft was sunk and gold was extracted until 1914. The vein occurs at or near a contact between the amphibolite schist on the east, and the Mariposa slates on the west. The shoot is from 2 to 12 ft. wide of white quartz, a little quartz and slate being on the foot-wall. Between February 1, 1913, and 1914 records show that 26,478 tons yielded \$57,029 by amalgamation and \$8941 by concentration. The Hardenberg company made no profit, but opened a shoot that assayed \$6.10 per ton. Physical conditions were not suitable for economic mining and the ore was not mined clean. Machinery installed is worth over \$15,000, and permanent improvements cost over \$30,000. Without the risk of losing much money the property is worth re-opening. James F. Parks, superintendent of the Plymouth Consolidated, is in charge. Thus another chapter is being added to the re-opening of old mines along the Mother Lode.

Plymouth, October 6.

PORTOLA. The Walker company is to erect a hydro-electric plant, utilizing water from tributaries of the Feather river. The head will be 514 ft., developing 1165 hp. The company is employing 125 men at its mine and mill.

COLORADO

According to the State mining commissioner, Fred Carroll, 350 new mining companies have been incorporated in this

MAP OF COLORADO.

State since the beginning of the year. The 1916 mineral output will exceed that of 1915 by 25%.

BRECKENRIDGE. On October 1 the Wellington Mines Co paid No. 12 dividend, equal to \$200,000, making \$600,000 for the year. Both mills are working full time, producing 2500 tons of concentrate in September.

(Special Correspondence.)—The new flotation plant of the Vindicator Consolidated is expected to be in full operation at an early date. The daily capacity will be 500 tons.

During September the Roosevelt drainage-tunnel was advanced 456 ft. The flow from the portal is 9650 gal. per minute. The heading is now in the Comstock lode, about 1751 ft. north-east from the Elkton main shaft.

At a recent meeting of the directors of the United Gold Mines Co. the following officers were elected: president, A. E. Carlton; vice-president, H. McGarry; secretary-treasurer, Ray Wilson, and superintendent, S. J. Russell.

It is reported that exploration in the Cresson mine has opened the downward extension of the rich vug that yielded over \$1,000,000 about two years ago. A special meeting of the

shareholders of the Cresson Consolidated has been called for November 7.

Cripple Creek, October 9.

SALIDA. The Standard Chemical Co. is to put on 250 miners to resume extraction of carnotite or radium-bearing ore in Paradox valley.

IDAHO

BURKE. The Sherman Development Co. has enlarged and straightened its 1800-ft. adit to allow of a horse being employed to haul cars. The adit is now being extended.

ENAVILLE. The 150-ton mill of the Empire Copper Mining Co. on the little north fork of the Coeur d'Alene river is to be doubled in capacity, according to A. J. Devlia, vice-president. Power is supplied by the Washington Water Power Co. A 22-drill compressor was recently installed, also a filter-press to reduce moisture in concentrate to 10%. The concentrate goes to Trail, B. C., at a cost of \$8.50 per ton for freight and treatment. Sixty men are employed. Three adits have opened long ore-shoots, the copper-content being from 3 to 5%.

WALLACE. Negotiations are pending for the purchase of the holdings of the Portland Mining Co., consisting of the Sitting Bull, Silver Tip, Mule Deer, and Red Dragon claims in the Beaver Creek district, by the Sunshine Mining Co., which also is endeavoring to secure the Parrot claim. The Sunshine company is controlled by the Day brothers.

ILLINOIS

ROSLICLARE. Labor troubles at the Rosiclare Lead and Fluorspar Mining companies' properties are holding-up 85% of the fluorspar production of the United States. Some violence is reported, and the Governor has investigated.

MICHIGAN

HOUGHTON. Copper production for this year will be fully 280,000,000 lb. If labor were sufficient the total would be 20,000,000 lb. more.

Savings deposits in this region are the largest in its history and six times those of three years ago, totaling \$19,000,000.

Early next month the Calumet & Hecla will use flotation in a small way as part of its treatment.

MISSOURI

JOPLIN. Zinc ore prices were steady but featureless during the past week, the range being from \$45 to \$65 per ton for 60% metal-content. There was a shortage of electric power for all work. The Oklahoma districts continue to turn-in large quantities of concentrates. The region output was 6984 tons of blende, 841 tons of calamine, and 762 tons of lead, averaging \$56, \$42, and \$74 per ton, respectively. The total value was \$478,641.

A 250-ton mill is to be built for the Eaglewood Mining Co. near Belville.

The new 400-ton mill of the A. R. G. Mining Co. north of Duenweg started work last week.

NEVADA

In Bulletin 640-F of the U. S. Geological Survey, Henry G. Ferguson describes the Golden Arrow, Clifford, and Ellendale districts of Nye county. The Clifford district is 35 miles east of Tonopah, on the road to Ely. Neither area has produced much ore; Ellendale is abandoned. The formations belong to the class of shallow-vein deposits in which the mineralization followed closely the extrusion of lavas. The gold-silver ores are in close association with andesite.

MINA. Thirty miles from this place the Olympia Mines Co. is operating the Royal George gold mine. Reserves of \$30 ore are estimated at \$1,500,000. A 50-ton mill is being erected.

TONOPAH. Last week 10 mines produced a total of 8602

tons of ore valued at \$170,776. The Belmont contributed 2445 tons; Tonojap Mining, 900; Extension, 2380; Jim Butler, 100; West End, 695; Rescue, 219; Midway, 77; Halifax, 158; North Star, 66; Montana, 36; and miscellaneous, 26 tons. Silver shipments were \$132,370 by the Belmont, \$59,619 by the West End, and \$79,300 by the Extension. The West End pays 5c. per share on October 21; this equals \$89,516.

NEW MEXICO

(Special Correspondence.)—At the Pacific mine a 31-ft. vein has been cut on the 600-ft. level. The head-frame and loading-bins for the wire-rope tramway are about completed.

The Socorro M. & M. Co. has eliminated concentrating tables in its mill and will turn all of its product into bullion. The change has effected an increased recovery. The plant treats 230 tons of ore daily.

The new 3-compartment shaft of Mogollon Mines Co. has reached a depth of 950 ft. Ore-pockets and sump are being cut, and development will be started from both the 800 and 900-ft. levels. This mine has been producing steadily for a number of years, and from a block of ground 2000 ft. long by 700 ft. high has yielded upwards of \$6,000,000 in gold and silver. This new development will open virgin ground, and undoubtedly will add large reserves to the property.

The Oaks company has been packing ore to custom mill all the week from development on the Clifton and Eberle mines. Mogollon, October 10.

OREGON

The U. S. Geological Survey has issued C. G. Yale's 'Mineral Report' of 11 pages on the gold, silver, copper, and lead output of Oregon during 1915. A total of 95 mines, from which 155,791 tons of ore was extracted, was \$1,861,796 gold, 117,917 oz. silver, 451,172 lb. copper, and 62,957 lb. lead. The total value was \$2,003,509. There was a decrease of 10 producers, but all metals save silver increased, the value being \$327,356 more than in 1914.

SHUFER. Mining operations will be resumed at the Congar mine in the next 30 days, according to C. C. Robbins, secretary-treasurer of the United Gold Mining Co. of Spokane, which recently purchased the property from the former owners. The old mill is being re-modeled. A 21-mile pipeline is being laid to provide water for power and milling purposes. As soon as these betterments are completed production will begin. The former operators of the property did not make a success because the concentrating system employed was not suited to the peculiar character of the ore. Exhaustive tests of different systems have been made, and a satisfactory recovery is possible by finer grinding before cyanidation. The former management used cyanide, but did not reduce the ore sufficiently to get the desired results. The plant has a capacity of 125 tons, provided by two 5 by 8-ft. tube-mills and five 20-ft. cyanide tanks. About \$150,000 had been expended on development and improvement up to the time the new company bought the property. About 5000 ft. of work had been done on the vein, blocking-out 100,000 tons of ore worth over \$1,000,000. The engineer who supplied these figures took 176 samples, and in assaying and calculating the total value he eliminated all values above \$20 per ton. It has been estimated that 31,000 tons above the first and second levels has an average of \$11 per ton. The calculated cost of stoping and milling is \$3. The shoot is continuous for 1100 ft., and has a lack of 200 ft. at its interior extremity. Another \$1,000,000 will be added to the resources by driving an adit 100 ft. below the upper block of the ore continues. This adit is now in 500 feet.

TEXAS

(Special Correspondence.)—It is reported here that Pachua in Mexico has been taken by the reactionists. Communication with Mexico City was cut. The mines will have to close

shortly on account of shortage of cyanide. At El Oro all the mills were at work save that of the El Oro company. No mines are being operated in the Zacatecas or Guanajuato districts. The general opinion in Mexico City is that the Constitutional government will be finally overcome by the many revolutionary forces forming in all parts of the country. Various pestilences are killing three or four times as many people as bullets.

Laredo, October 1.

UTAH

ALTA. It is reported that the mining companies of the Big Cottonwood district are considering the improvement of roads between their mines and Park City for handling of ore to the latter instead of down the canyon. Early in November the new Alta-Cottonwood railway is expected to be finished.

Three shifts are driving the Alta Tunnel & Transportation Co.'s adit, which is now in over 2000 ft., two shifts drilling and the third cleaning out. A suction-fan at the portal improves ventilation considerably.

BINGHAM. The Utah Consolidated company is paying quarterly dividends of 75c. per share, and will close the current year with \$3,000,000 cash and quick assets. In 1910 it was reported that the mine was nearly worked out, but in the five years following the output from 1,080,264 tons of ore was 29,799,987 lb. copper, 63,620,280 lb. lead, 1,424,512 oz. silver, and 79,859 oz. gold. Dividends totaled \$8.50 per share.

GOLD HILL. The Western Pacific is to construct a 41-mile railway into Deep Creek, from Wendover to this place in Tooele county, where the Western Utah Copper Co. is working.

PARK CITY. Thirteen mines in this district shipped a total of 6443 tons of ore and concentrate during September.

SALT LAKE CITY. The Utah Copper Co. expects to have its leaching plant at work within two months. Good progress is being made at the acid plant and improvements in the mills.

WASHINGTON

HUNTERS. The Chloride Hill Mining Co., capitalized at 1,000,000 \$1 shares, has been organized by Spokane men to take over and develop the old Santiago silver mine, on the Columbia river, two miles from this place in Stevens county. E. G. Ross is president and R. B. McClary secretary-treasurer. The property is one of the oldest in the county, and was fairly well developed by former owners. Because of lack of transportation facilities, the high cost of freight and treatment charges, and the low price of silver, the property was abandoned several years ago, except that enough work was done each year to cover assessment requirements. Dumps contain 10,000 tons of ore. The lode contains a high-grade shoot.

NORTHPORT. As deep development of the Great Western and Last Chance mines near here have been a disappointment, the Norman Mines Co. is to suspend work. About \$25,000 of zinc carbonate ore was shipped to Eastern smelters, but the shoot showed no persistence with depth.

RURIC. During the quarter ended September 30 the Knob Hill Mining Co. received \$17,708 from 12 cars of ore sent to Trail, B. C. It cost \$10,563 to mine and treat this ore. There was \$3194 paid on the Alpine claim, which has good promise. The cash balance is \$6713.

WYOMING

Cody. A cave of high quality sulphur has been broken into at the Midwest Sulphur Co.'s mine. The walls are lined with 12 to 18 in. of a purer of 99% purity. Present profits are \$2000 monthly. An initial dividend of 1% was paid on October 1. At present prices the ore in the quarry is worth \$750,000, and that in new ground \$1,000,000. The net value is \$151,000. The production cost is \$13 per ton of sulphur.

CANADA

BRITISH COLUMBIA

GRAND FORKS. During the year ended June 30, 1916, the Granby Consolidated Mining, Smelting & Power Co. produced 42,198,083 lb. copper, 44,848 oz. gold, and 487,845 oz. silver, against 26,638,912 lb., 31,388 oz. and 377,881 oz., respectively. The tonnage reduced last year was 1,897,251 tons, against 1,098,020 tons in the previous year. The Anyox plant reduced 822,919 tons. The matte is sent to Grand Forks for conversion into blister copper. Reserves total 9,947,000 tons of 2 to 2½%, 3,718,000 tons of 1 to 1½%, and 9,491,000 tons of less than 1% copper-content, a total of 23,156,000 tons. Development at Phoenix did not replace the ore mined by 721,409 tons; at Anyox there was an increase of 182,833 tons over that extracted. Costs were reduced from 10.09 to 8.54c. per lb. Sales of metals amounted to \$9,299,337, more than double that in 1914-15. The profit was \$3,819,295, nearly four times larger. Dividends were \$899,911. The surplus is \$2,919,384, compared with \$929,168.

SILVERTON. From settlements of silver-lead and zinc concentrates in September the Standard company made a profit of \$53,399. The revenue was \$88,863. The balance on August 31 was \$287,662.

YMLR. For the sum of \$75,000 the Canadian Pacific claims of Edward Peters and others are to be sold to John Arbuthnot of Victoria and New York partners. Four veins contain good value in gold and silver.

ONTARIO

One of the largest known deposits of barite is that of the Premier Langmuir Mining Co. of Toronto, J. A. McIntosh president. The mine is on Night Hawk lake, reached by water from Connaught station. Fifty thousand tons is the estimated quantity. Native silver is found with the barite.

PORCUPINE. During September the Dome mill treated 38,300 tons of \$4.68 ore. Costs were 76c. for mining, 60c. for development, 10c. for crushing, 82c. for treatment, and 31c. for general expenses.

KOREA

During August the Oriental Consolidated treated 25,210 tons of ore for bullion worth \$128,751. Generally everything is working well.

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports a total recovery of \$128,065 in September.

At the monthly meeting of the San Francisco Section of the AMERICAN INSTITUTE OF MINING ENGINEERS, held on October 10, the following resolution was passed unanimously:

Resolved: That it is the sense of the San Francisco Section of the American Institute of Mining Engineers that Paper No. 150, by Wm. H. Shockley, entitled: 'The Economic and Social Influence of Mining with Special Reference to the United States,' as finally revised by him, gives evidence of wide reading and careful study, is manifestly temperate in tone, and his findings are chiefly based upon authoritative publications which are cited, and should have been accepted as a contribution to the Transactions of the International Engineering Congress, with the full consent and approval of the American Institute of Mining Engineers as part of that Congress, and that the action of the directors of the American Institute of Mining Engineers in censoring the publication of that paper is unwarrantable, in that the part of Mr. Shockley's paper apparently offensive to the Anthracite Section of our Institute is but a citation from official documents, authorized by the State of Pennsylvania and the Government of the United States, the conclusion therefrom being his own, and frankly so stated.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

F. F. BOSTWICK is at New York.

JOHN W. FINCH has gone to China.

O. B. PERRY is here on his return from the Yukon.

JOHN SEWARD has been examining mines in Ontario.

H. D. GRIFFITHS has returned to London from Burma.

S. M. SOUPCOFF has returned to Pittsburg from Alaska.

JOHN F. COWAN, of Salt Lake City, is at Tucson, Arizona.

DEANE P. MITCHELL is expected here shortly, from London.

R. W. ATWATER has been on a visit to the Coeur d'Alene, Idaho.

ROBERT B. BRINSMADE has returned from St. Louis to Phebia, Mexico.

J. B. TYRRELL has been inspecting the Rice Lake goldfield, in Manitoba.

W. C. SEAGRAVES has resigned as manager of the Kennecott mine, Alaska.

H. H. KNOX has gone from New York to London, on his way to Siberia.

J. VOLNEY LEWIS has returned from Alaska to New Brunswick, New Jersey.

H. FOSTER BAIN sails by the *Empress of Japan* from Vancouver on November 2.

A. E. DRUCKER has moved his office from London to 1502 Pacific street, Brooklyn, N. Y.

E. COPPEE THURSTON has left London and will reside in California, probably at Berkeley.

V. A. HART has been appointed manager of the Walker copper mine at Portola, California.

J. J. McDONALD is making a two months' professional trip to Chicago, New York, and the East.

K. C. LI has been appointed president of the Hunan lead smelting works by the Hunan Mining Board.

B. L. THANE, manager for the Alaska Gold Mines Co., has been in San Francisco, on his way to New York.

WILLARD S. MORSE is at Chuquicamata, Chile, where his address is care Chile Exploration Co., via Antofagasta.

C. O. LINDBERG of Los Angeles has been examining zinc mines in the Kootenay district of British Columbia.

EDWIN E. CHASE and son have started for the Granby district, British Columbia, where they will be until November 1.

D'ARCY WEATHERIE is at Toronto, having traveled through Trans-Caucasia, Persia, the Altai, and Korea. He will proceed to London early in November.

FREDERICK BRADSHAW, manager for the Tonopah Belmont Development Co., has been to the Surf Inlet mine, on an island off the coast of British Columbia.

W. A. CARLYLE is a director for the British-America Nickel Corporation. He went to Butte recently to engage E. P. MATHEWSON as general manager.

J. H. GARRY and R. J. KING, of the Tonopah Belmont Development Co., were recently at Prince Rupert, British Columbia, on their way to Surf Inlet on Princess Royal island.

EDWIN HIGGINS has resigned from the U. S. Bureau of Mines and California Industrial Accident Commission to open an office in San Francisco as safety and efficiency engineer.

V. E. LEDNICKY has been appointed chief geologist of the Philippine Bureau of Science. Mr. Lednický is a graduate of the University of Kansas and during the past two years has been connected with the Bureau of Science as mining engineer.

The Western Branch of the CANADIAN MINING INSTITUTE has been definitely arranged to meet at Trail, B. C., on Thursday, October 26. E. Jacobs is secretary at Victoria.

THE METAL MARKET

METAL PRICES

San Francisco, October 17

Antimony, cents per pound.....	11.50
Electrolytic copper, cents per pound.....	29.25
Pig lead, cents per pound.....	7.25—8.50
Platinum: soft and hard metal, per ounce.....	\$90—94
Quicksilver, per flask of 75 lb.....	78
Spelter, cents per pound.....	12
Tin, cents per pound.....	42
Zinc-dust, cents per pound.....	20

Quicksilver bulletin of the U. S. Geological Survey is to hand. In 19 pages the 1915 history of the metal is discussed.

ORE PRICES

San Francisco, October 17.

Antimony: 50% metal, per unit.....	\$1.00
Chromite: 40% and over, f.o.b. cars California, per ton.....	13.99—16.00
Magnetite: crude, per ton.....	8.00
Manganese: 50% (under 35% metal not desired).....	11.00 and up
Tungsten: 60% WO ₃ , per unit.....	17.00

New York, October 11.

The demand is light and only small quantities have moved, those bringing \$1.10 to \$1.25 per unit, according to quality.

Molybdenite: For this mineral there is a good export demand, but it is difficult to obtain. Small quantities have been taken at \$1.50 to \$1.75 per lb. for MoS₂ contained.

Tungsten. Several hundred tons have changed hands at \$17 per unit. Buyers are showing more confidence, and it is believed that the bottom of the market has been touched. One contract has been made to cover all of 1917, the price being \$17, other contracts on the same basis are being negotiated.

EASTERN METAL MARKET

(By wire from New York.)

October 17. Copper is dull though steady, quotations are for prompt metal, lead is dull and unchanged, spelter is quiet and easy.

SILVER

Below are given the average New York quotations, in cents per ounce, of the silver.

Date.	Average week ending
Oct. 11.....	67.87
" 12 Holiday.....	68.10
" 13.....	67.87

Bradon produced 2,970,000 lb. in September; Arizona Copper, 1,180,000; Chile Copper, 4,038,000; Greene-Canaan, 4,900,000.

United Verde Extension is producing 3,000,000 lb. per month from 8000 to 8500 tons of ore.

Shannon is paying two dividends of 25c. each on November 15. United Verde on September 20 paid 75c. per share; this is the fifteenth consecutive dividend of similar amount.

United States Smelting, Refining & Mining Co. pays, on October 14, \$1 per share on common and \$7 1/2c. on preferred stocks.

Eastern Metal Market

New York, October 11.

Copper is quiet, but strong.

Zinc was feverishly active on the 5th, but the excitement lasted only one day, practically. The spot price went up to 10c. St. Louis, but has since declined $\frac{1}{8}$ c.

Lead continues steady in a quiet market.

Tin is higher because of the German submarine activity. It is now quoted at over 42c.

Antimony has a better tone.

Aluminum is stronger because of the scarcity of virgin metal.

In iron and steel but little change is to be quoted. One feature that stands out is the generally accepted belief that prosperity is here to stay a long time, a belief that some interests are willing to substantiate by contracting for material into 1918. Railroads, for instance, have closed for 100,000 tons of rails for first-quarter delivery in 1918. The railroads continue to buy cars, evidently having determined that lower prices are not to be expected for months to come. The heavy buying of steel-making iron is subsiding, consumers having covered their needs, but foundry iron is gaining in strength. For months it has been a laggard. The activity of a German submarine off the New England coast has sent up marine-insurance rates, also freight-rates, and some shipments have been held-up. Munition shipments, however, are going forward without interruption. A shortage of cars is hampering the movement of Lake Superior iron ore from Lake Erie docks; also interfering with shipments of coke, the Pennsylvania Railroad refusing to ship coke in box-cars. The base price of tin-plate has been fixed at \$6 per box for the first half of next year.

COPPER

The market is quieter, but its strength is not impaired, and hardly likely to be in view of the well-booked condition of the producers. As a matter of fact, they are independent, as they can afford to be. Near-by metal does not appear to be of great interest to consumers, but there is a fair amount of inquiry for next year, particularly the first quarter. As to the quotation for this position, there is some difference of opinion, but it is certain that it can be obtained at from 27 to 27.50c. Late last week, a manufacturer was offered first-quarter copper at 27c., but at the moment could not make up his mind to buy. The following day he offered to pay the price mentioned, but was told that 27.25c. was the price. Second-quarter Lake has sold at 27.12 $\frac{1}{2}$ c. Spot electrolytic is quoted at 29c., November at 28.50c., and December at 28c. Lake is nominally the same. A dealer parted with a round lot of spot electrolytic at 28.50c. Activities of the German submarine on this side of the Atlantic has had no pronounced effect on the market. Incidentally, in the past few weeks about 4,600,000 lb. of copper has been lost through the sinking of vessels, out of which some of the financial papers have tried to make capital. Exports to the 10th totaled 7125 tons. The London quotation yesterday for spot electrolytic was £142, compared with £140 a week previous. Exports of brass in bars, plates, etc., in the first seven months of this year totaled 51,372 tons, against 18,089 tons in the same period of 1915. The brass mills are further than ever behind in deliveries. Where they can and choose to quote on deliveries inside of two or three months they expect premiums.

ZINC

Thursday of last week was a wild day in the spelter market, and prices went up with a rush to 10c., St. Louis, even to 10.12 $\frac{1}{2}$ c., while in New York, from 10.17 to 10.37 $\frac{1}{2}$ c. was asked. Buyers paid 10c., St. Louis, for prompt and October, and 9.75 to 10c. for November and December. Heavy pur-

chases were made by those who ordinarily are sellers, for what reason is not apparent, until they were short of metal where-with to make deliveries. On Friday there was less doing, and by Monday of this week, sellers were looking for business and the quotations had declined several points. Yesterday prime Western was quoted at 9.75c., New York, and 9.50c., St. Louis, November at 9.37 $\frac{1}{2}$ c. St. Louis, and December, at 9.25c. Sellers say that the market has been quieted by the activity of the German submarine, but just why this is so is not explained. If brass or zinc is sent to the bottom of the sea it means that just so much more will have to be supplied. The sinking of six ships by the German submarine has not checked the exportation of munitions from this port. The demand for brass-mill special is not heavy, nor was it so during the flurry referred to. The mills are covered, and in addition, are using large quantities of high-grade scrap. Exports from the 1st to the 10th totaled 3032 tons. The spot price at London yesterday was £56, against £52 a week previous. There has been no change in the price of sheet zinc, and for carload lots 15c., f.o.b. mill is quoted, 8% off for cash.

LEAD

The A. S. & R. Co. continues to quote 7c., New York, and 6.92 $\frac{1}{2}$ c., St. Louis, while the independents ask 7 to 7.12 $\frac{1}{2}$ c., New York, and 6.85 to 6.90c., St. Louis, but it is safe to assert that but little business is being done above 7.05c., and most of it is at 7c., New York, unless spot shipment is wanted, when a premium is asked. The market has been quiet, but steady, throughout the week, and features of interest are lacking. Exports in 10 days totaled 1882 tons. The London quotation yesterday was £30 15s., against £31 15s. a week previous.

TIN

The market was stirred to great activity on Monday, the 9th, by the news that a German submarine had sunk ships off the New England coast. Great uncertainty prevailed for a time as to the price of spot, but at last it was fairly well established at 42.75c., although there were not many sellers at that figure. Consumers showed great interest in futures, and probably 500 tons was taken, 40.75 to 41c., being paid for November and December deliveries. Incidentally, Banca was active and sold around 41.60c. Late last week a good business was quietly done, and several hundred tons of Straits changed hands at around 39.75c. At that time Banca was sold for delivery from the Far East at 38.75c. The latter buying was regarded as interesting, as indicating a resumption of shipments from the East. For a time they had been halted. In this market there has been a surfeit of spot Banca, and it was thought that some of the holders would lose money. There is now afloat, en route to this country, 2245 tons of tin, while the arrivals of the month total 1015 tons.

ANTIMONY

A good business has been done in metal in bond, the prices ranging from 9.50 to 9.75c., but re-sellers offer the metal at 11.50c., duty paid.

ALUMINUM

Virgin metal is scarce, and prices have advanced to 63 and 65c. Re-melted material, 98 to 99% pure, guaranteed, is strong at 61 to 62c., while No. 12 re-melt alloy is offering at 47c. Sheet aluminum is held at 80 to 85c. for prompt deliveries. The producers' contract price for 1917 is unchanged at 35c. for ingots, but they are understood to be out of the market. In the first 8 months of 1916 exports of aluminum and manufactures thereof totaled \$4,867,743, against \$2,994,072 for the entire year of 1915. The British Government has been a heavy buyer.

Recent Publications

U. S. Bureau of Mines, Washington, D. C., 1916:
SAFE PRACTICE AT BLAST-FURNACES. A manual for foreman and men. By F. H. Willeox. Technical Paper 136. P. 73. Ill., index.

UNDERGROUND WASIES IN OIL AND GAS-FIELDS AND METHODS OF PREVENTION. By William F. McMurray and James O. Lewis. Technical Paper 139, petroleum technology 39. P. 27. Illustrated.

ORE-SAMPLING CONDITIONS ON THE WEST. By T. W. Woodbridge. Technical Paper 86. P. 96. Ill., index.

This is a useful work, and an abstract is to be made for the Press.

HEALTH CONSERVATION AT STEEL MILLS. By J. A. Watkins. Technical Paper 192. P. 34.

Both employers and employees are advised to secure this paper that speaks straight out on safety-first and health.

RESCUE AND RECOVERY OPERATIONS IN MINES AFTER FIRES AND EXPLOSIONS. By James W. Paul and H. M. Wolfin. Page 109. Index.

This pamphlet is the result of serious studies covering a period of considerable time on what the Bureau believes to be the best method in rescue and recovery operations in both coal and metal mines after fires and explosions. It outlines a method of procedure for the operators and miners to follow in such emergencies, and explains just what part the Bureau is expected to take in such work. We are of the opinion that this paper should be in the hands of operators and every mine superintendent in the country.

A METHOD FOR MEASURING THE VISCOSITY OF BLAST-FURNACE SLAG AT HIGH TEMPERATURES. By A. L. Feild. Technical Paper 157. P. 27. Illustrated.

The Bureau of Mines has been conducting for the past year an investigation of the physical and chemical properties of blast-furnace slags at high temperatures, the work being a part of the research program of the metallurgical division. The present publication is the first of a series of reports on commercially important slag problems. Besides being of timely interest to metallurgist and blast-furnace men, on account of the increasing demand on their part for an investigation of the viscosity and desulfurizing properties of slags, this publication represents pioneer work in the field of high-temperature physico-chemical measurements. In attacking the problem Mr. Feild developed a high-temperature torsion viscometer which can be operated at temperatures as high as 1600° C., and which yields results expressed in terms of specific viscosity.

U. S. Geological Survey, Washington, D. C., 1906.
THE GOLDEN ARROW, CALIFORNIA, AND ELLENVILLE DISTRICTS, NYE COUNTY, NEVADA. By H. G. Ferguson. Bulletin 619. P. 11. Illustrated.

NOTES ON SOME MINING DISTRICTS IN EASTERN NEVADA. By James M. Hill. Bulletin 618. P. 211. Ill., map, index.

Both of these publications have been abstracted for the Mining Summary of the Press.

EXPERIMENT FROM THE FLOTATION LABORATORY. By C. Y. Kato and others. P. 40. Illustrated. Bulletin. School of Engineering and Metallurgy, University of Missouri, Rolla, 1916.

This is a laboratory flotation machine, 60" in diameter, in which the flotation values of oils, effect of frothing and non-frothing oil, carbon and its oil, concentrate, oil, and oil supply flotation oils, and an attempt to float copper carbonate.

NOTES ON THE RECOVERY OF COPPER FROM THE ORES BY T. A. C.

ING AND PRECIPITATION, IN THE UNITED STATES, AND APPLIANCES USED IN CONNECTION THEREWITH. Metallurgical report No. 1. By J. D. Connor. P. 56. Illustrated. Department of Mines, Adelaide, South Australia, 1916.

Details and summary of plants visited during 1915. Although only two were at work, the author has collected a large amount of general data.

PLANE SURVEYING AND EXERCISES IN SURVEYING. Combined edition. By John C. Tracy. P. 1004. Illustrated. For sale by the MINING AND SCIENTIFIC PRESS. Price \$3.

RESOURCES OF SANTA CRUZ COUNTY. By Allen T. Bird. P. 27. Bulletin 29, county resource series No. 1. University of Arizona, Bureau of Mines, Tucson, 1916.

Industrial Notes

Information supplied by the manufacturers.

P. H. Reardon has severed his connection with the GENERAL MACHINERY & SUPPLY Co. of San Francisco, having disposed of his interest to his associates. Joseph A. Buckley succeeds him as president. A. L. Green is vice-president, and H. F. Jurs is manager.

Charles A. Baechtold has arranged with the LINGERWOOD MANUFACTURING Co. of New York to establish a regular branch office at the Hibernian building, Los Angeles. From this office he will take care of business from the southern half of California, Arizona, and Nevada.

A leaflet issued by the EMPIRE CONCENTRATOR Co. of Denver briefly describes its machine, which is in successful operation in the Idaho Springs district of Colorado. Advantages claimed are large capacity—35 to 50 tons per 24 hours on 30-mesh feed—clean separation, small floor-space, simplicity, and low cost, water, and power consumption.

A 12-page booklet of the LEE ELECTRIC RADIATOR Co. of Chicago describes and illustrates its radiator. It is claimed that this type of heater has been in successful use for several years in offices, homes, and automobiles. The cost of operation is low. Compared with hot water and steam systems the electric radiator has temperature values greater than the first and nearly equal to the second system.

Robert C. Clifford, for the past four years district sales manager for the United States Cast Iron Pipe & Foundry Co. in charge of its St. Louis and Kansas City offices, is now associated with the WALTER A. ZENICKER SUPPLY Co. in St. Louis, in charge of its rail department. Bulletin 207 of this concern, of 10 pages, covers its business in rails, locomotives, cars, machinery, steel piling, and tanks of all types.

A new company has been formed for the purpose of taking over and operating the Peter McFarlane & Sons Iron Works of Denver. The leading spirits in the new company are Henry Eggers, president, and E. McFarlane, secretary and treasurer. Mr. Eggers is well known to the mining fraternity by reason of his connection as department manager with the Mine and Smelter Supply Co. of Denver for many years. He has resigned his position with the latter company and will give all his time and attention to the affairs of the new company, to be known as the McFarlane Eggers Machinery Co. The business of the company will be the manufacture and sale of mining and millinery machinery, including the development of a number of specialties. The launching of this new enterprise under such favorable circumstances as the present prosperous condition of the metal mining industry, combined with the experience and knowledge of the executive heads of the company, in business, is becoming an influential factor in Middle West manufacturing affairs.

EDITORIAL

T. A. RICKARD, Editor

TUNGSTEN is in fair demand and the market is firm at \$17.50 to \$20 per unit. The Allies have been placing orders in New York. The outlook is good for those mine operators that did not set their expectation of prices too high.

ACCORDING to the front page of the year-book issued by the American Institute, that organization is in the control of 15 "ditectors." Assuming that this is a misprint for 'detectors,' we are better able to understand the Shockley episode.

MINING engineers wishing to render patriotic service by joining the National Engineer Reserve can obtain particulars of the qualifications for a commission by writing to the Chief of Engineers, War Department, Washington, D. C. A number of Californians have volunteered for this service.

COPPER production was at its maximum last May, when the total output of domestic refineries was 190 million pounds; just now it is at the rate of about 165 million pounds per month. Hot weather, labor troubles, and the inability to secure delivery of needed equipment caused production to decline to 150 million pounds per month during mid-summer.

BBETTER means than strikes ought to be found for distributing prosperity among the laboring men, as also a better method should be discovered for sharing the evil of bad times. Arbitration is the obvious corrective for so much clumsy friction, but that assumes the interplay of intelligence and goodwill. In the end it is the cheapest as it is the fairest method for adjusting differences.

DEMANDS for a 7-hour day are foreshadowed by Mr. John P. White, president of the United Mine Workers. Of course, the workers have a 'right' to ask for as much as they can get and a little more, for that is what most of us do, but the insistence on the 8-hour interval as a normal shift becomes cynical in face of the further demand by organized labor. Are capital and labor to be at war always; if so, why pretend to placate?

COPPER dividends are most satisfactory and shareholders have reason to feel happy. The recent contract for the sale of 448 million pounds of metal to Great Britain and her allies means a profit of \$70,000,000 to shareholders during the first half of 1917. But it is foolish to talk, as brokers' circulars are doing, of copper

mining as an 'investment' at a time when so many essential factors are uncertain. It is a reasonable and most attractive 'speculation,' but it is no game for widows and orphans.

ON another page we publish a useful article describing a method for correcting the measurements made with a steel tape in mines. This article is written by Mr. Walter S. Weeks, Associate Professor of Mining in the College of Mines, University of California. Surveyors will be glad to have the use of the chart prepared by Professor Weeks; it affords a method for correcting, in one operation, all of the errors incidental to the stretch, sag, temperature, and initial error in a tape of any length up to 200 feet, and at any angle with the horizontal.

IAN HAY suggests that War will have at least one humanizing effect. He refers to the comradeship in the trenches, whereby the officer type of man learns to respect the courage, devotion, and intelligence of the men temporarily under his command, while the men correspondingly learn to appreciate the fact that their social superior is no mere child of fortune but a brave leader, quite willing to sacrifice himself in behalf of the national cause and anxious at all times to consider the welfare of those in his charge. This may not describe all the officers or all the men, but the suggestion of a real social solidarity and a mutual good understanding is unquestionable. It will have both political and economic consequences pleasant to contemplate.

THE Arizona Bureau of Mines issues a circular on the sale of ore and quotes the *Mojave Daily Miner* in a protest against "the extortion practised by the smelter concerns." The further remark is made: "There is a question whether any newspapers or magazines in the entire United States are prepared to take a stand in this matter and show up the robbery to which the shippers are subjected." This is incorrect; there are many newspapers and magazines that will give space to a discussion of the subject if presented in good faith and accompanied by a reasonable statement of facts. This paper is prepared to publish such a statement, as the *Mojave Daily Miner* and the Arizona Bureau of Mines ought to know. No good comes from calling people names or making vague assertions. For instance, the circular asserts that on a 10% copper ore the shipper receives only \$17.40 from the Arizona smelters. We would like to see a copy of the settlement between the shipper and the smelter, with an explanation of the circum-

stances. The smelting business is not conducted by Sunday-school teachers, of course, and advantage is taken of the little fellow in the ore business as in other affairs of life, but wrongs are not redressed by unsupported charges. We invite the Bureau of Mines to make good.

STATISTICAL prosperity is a new term applied to existing conditions in the United States. The inference is made that our prosperity is largely fictitious owing to a one-sided foreign trade, the persistent influx of gold, and the increasing cost of living. Neither a nation nor an individual can continue to sell continuously without buying from or lending to its customers. Hence the ingenious suggestion, made in the *New York Tribune*, that this country should refuse to receive further importations of gold. This can be bracketed with the unauthorized suggestion, made recently in the *London Statist*, that Great Britain may have to suspend specie payments. Evidently the abnormality of conditions is stimulating radical notions and reckless remedies.

WE publish a report of the discussion on flotation at *Globe*, on the occasion of the recent meeting of the American Institute of Mining Engineers. The many to whom the subject is of interest will find it well worth while to read what Messrs. David Cole, Rudolf Gahl, Frederick Laist, E. P. Mathewson, L. D. Ricketts, and O. C. Rakston said on that occasion. Apparently mill-men are still slow to appreciate the full scope of flotation; they cling to gravity methods of concentration even for the finer stuff that is peculiarly amenable to flotation. The part to be played by the new process in the flow sheet of a modern mill is still a matter for debate. As our readers will see, the discussion closed with a number of questions. That was fitting. Frank replies to many basic queries are still lacking. To formulate questions that recognize the essential factors is the best way to move forward to the solution of any technical problem.

LABOR is profiting from the expansive metal market and the wages of miners throughout the West have been raised, but what of the technical man on the staff of the mining company? Is he sharing the prosperity of his employer? Yes, in some instances; in others he finds it to his advantage to leave the office or laboratory and go to work on day's pay in the mine or mill. At Miami the pay roll of 1000 men now calls for the distribution of \$416,000 monthly, so that the average pay is \$416 per month. Miners are getting from \$4.50 to \$5.10 per shift. And yet the cost of producing the copper has not risen, this satisfactory result being due to the larger tonnage mined and milled, together with the improvements made in the mining and metallurgical processes to which the ore is subjected. One of the remarkable features of recent work in Arizona is the increased capacity obtained in mills without making expensive changes or costly additions to the plant; thus

the Miami mill with its former rating of 2000 tons daily is now treating 5000 tons and shortly will be doing even more. For that the technical man is to be credited; the laborer either on or below the surface is working no harder for his increased pay; it is brain not muscle that enables wages to be increased without invading the profit of the mine-owner. At Miami the members of the staff receive a bonus of 20% on their salary. They have earned it. We hope other companies will take the hint.

Prospecting and Prospectors

The passing of the old-time prospector has been bemoaned by several contributors to our 'Discussion' department. Many engineers appear to regard the prospector as a romantic humbug, while at least as many look upon the mining engineer as a pedantic prig. In this issue Mr. L. I. Rowland calmly states that "the average engineer falls short of the standard" by which the prospector measures him, especially if he be a graduate from a mining college. This is a fair retort to the technical men that complain of the time they waste in looking at the holes in the ground that the prospector calls mines. The ideal prospector is as rare, and no rarer, than the ideal engineer. The prospector to whom Nature is an open book is as uncommon as the engineer to whom the earth's crust is transparent; yet it is manifest that while much has been done to train the engineer, nothing has been done to educate the prospector, unless we regard the issuance of official bulletins by the Government bureaus as an educational propaganda for the unlettered. Behind all the discussion lurks the fundamental guess, how to find a mineral deposit and how to make money out of it. No more pertinent problem can be attacked in our pages. Two years ago we had a symposium on the subject, a number of experienced engineers recorded their ideas, and the trend of opinion was duly summarized in these columns. However, the question is iterative and we are aware that since then we have added several thousand new readers to our clientele. Upon a number of points most of us will agree: (1) that the cream of the mineral deposits has been skimmed, (2) that the prospector has fewer chances of making a rich discovery at grass roots, (3) that there is plenty of money for exploratory work, even if the old-fashioned grubstaking is less common, (4) that Government patronage of the prospector would breed graft and idleness, rather than effective search for mineral, and (5) that much of the public domain is sequestered by means of idle locations, that is, by the legal holding of ground without any real prospecting being done. Other factors concerning which we may be less in accord are (1) that the untechnical prospector has had his day and that the search for ore must be done henceforth largely by younger men with a scientific training, (2) that it would be well to combine the unscientific instinct of the old type with the scientific knowledge of the new school, (3) that the mining law should be modified so as to afford better protection to the genuine discoverer, (4)

that the publication of accurate information concerning the occurrence and characteristics of mineral deposits is the proper function of the State and Government, (5) that the building of roads and trails is the most immediate service that the State or Government can do for the further expansion of the mineral industry, and (6) that depreciation of the prospector or sneering at the young explorer is no good to anybody.

The Wilmington Decision

In the two preceding issues of this paper we have given our readers the text of the opinion submitted by Judge Bradford in the suit of Minerals Separation, Limited, v. Miami Copper Company. This decision of the U. S. District Court of Delaware in the second big flotation case has been made known on the eve of the revision of the first, or Hyde, case, taken before the Supreme Court of the United States on a writ of *certiorari* from the U. S. Court of Appeals in San Francisco. While the issues involved are not exactly the same, the main point, namely, the validity of Minerals Separation's basic American patent, No. 835,120, is common to both litigations. It will be recalled that in the first trial of the Hyde case, before the U. S. District Court at Butte, Judge Bourquin rendered a decision upholding the validity of patent 835,120, more particularly as against the defendant's claim that it had been anticipated by Froment's British patent. "The decision appears to have been largely influenced," so said the Court of Appeals, "by the consideration that the appellee's patent had gone into extensive and successful use" in foreign countries; but at that time, despite the expenditure of \$60,187 by Minerals Separation in the United States, not a single plant using their process, had been installed in this country. The Court of Appeals, in reversing the lower court in Montana, found that "each step in their [M. S.] process was fully described in more than one of the patents of the prior art, with the single exception of the reduced quantity of oil which they use." This reduction was "a valuable contribution to the art," but it was only a logical effort at economy and could not "be made by itself, or in combination, the subject of a patent." The Court affirmed that Minerals Separation could not take from others "the right to use oil economically" and it refused to give the owners of patent 835,120 "a monopoly of that which others had discovered." So said the U. S. Circuit Court of Appeals in San Francisco. Now we have another District Court upholding the Minerals Separation patent in a second litigation at the very moment when the first litigation is to be reviewed by the Supreme Court of the United States. Obviously, it would have been well if both cases could have been taken under final advisement at the same time. As it is, an appeal from Judge Bradford's decision has been made already and will be heard before the Court of Appeals at Philadelphia, but no conclusion is likely to be reached before the Supreme Court finishes the Hyde case.

The Wilmington decision is that the diminution of oil

to less than 1% of the weight of the ore is patentable. The discovery claimed to have been made by A. H. Higgins, in March 1905, acting under the supposed direction of Messrs. Subman, Picard, and Ballot is recognized by the Court as a genuine consequence of experimental work on the Cattermole patent. Thus patent 835,120 is pronounced the legitimate offspring of patent 777,274; in other words, a process for floating sulphide minerals was evolved logically from a process devised to sink them. Before that time, 1905, the proportion of oil used in flotation processes had been much greater; it had decreased in six years from a ton, or even more, of oil per ton of ore in Elmore's first bulk-oil process to three pounds in the Elmore vacuum process. The Court ignores this rapid diminution in the quantity of oil and finds that below 1% (or 20 pounds per ton) a new metallurgical principle comes into play. Judge Bradford sustains claims 1 and 12 of patent 835,120, specifying the use of less than 1% of oil, but declares invalid claim 9, which calls for "a small quantity" of oil. In short, he plants his decision squarely upon the ground that there is a difference in result growing out of the use of less than 1% of oil as distinct from more than 1% of oil. The Judge does not state what this difference is; apparently he is unable to explain the difference; although both parties to the suit acknowledged that the presence of some oil or other modifying agent is necessary to cause the bubbles to persist long enough to serve as a carrier of mineral. Moreover, Judge Bradford disregards the evidence brought forward by the defendant to establish the identity of result when more than and less than 1% of oil is used. We refer, of course, to the famous bubble-holder experiments, the importance of which was enhanced by the fact that they were introduced first by the plaintiff, not by means of experiments conducted before the eyes of the Court, but through a cinematographic exhibition. In these pictures a bubble of air, held in an inverted cup at the end of a glass rod, was shown in the act of being moved from place to place beneath the surface of the water contained in a vessel at the bottom of which rested various particles of mineral. The proposition was advanced by the plaintiff that particles of mineral oiled with amounts of oil such as would be attached to them when the proportion of oil was over 1% of the ore would not adhere to the air-bubble and therefore could not be floated by the bubbles in the form of a froth. This was coupled with the converse proposition that when the proportion of oil used was less than 1%, the mineral particles would adhere to the bubble and could be raised to the surface of the pulp. The plaintiff's expert made an estimate of the amount of oil that would adhere to the mineral particles when more than 1% was used and also when less was used. Proceeding on this basis, he applied oil in varying amounts to metal discs and mineral particles in order to show that the particles carrying larger amounts of oil would not adhere to the air-bubbles, but that those particles more minutely oiled would adhere to the bubble; also that the particles not oiled at all would likewise ad-

here. The experts for the defendant proved that the particles used in these experiments were several thousand times heavier than any mineral floated in a working process of froth-concentration. The experiments were repeated before the Court by the defendant's experts, who showed that the mineral particles adhered to the air-bubble regardless of the amount of oil on them. Particles of mineral were oiled by submerging them in oil and lifting them out coated with the maximum amount of oil that would adhere to them. These particles were then dropped into a vessel of water and the air-bubble applied to them, with the result that they instantly adhered to the air-bubble and were raised with the bubble when the bubble-holder was lifted. In short, these experiments either proved nothing or they proved that there was no particular virtue in the arbitrary limitation of the proportion of oil at 1%. In order to elucidate the technology of the process a large number of flotation operations were performed in Court. In these experiments various amounts of oil were used to demonstrate that the proportion of oil was not the decisive factor. In several instances the highest grade of concentrate and the best recovery were obtained when using oil up to 25% of the ore by weight. After each experiment the heading, tailing, and concentrate were assayed separately and the results put in evidence. All of this seems not to have impressed the Judge; he makes no reference to the bubble-holder experiments or to the flotation tests, although it is well known that the plaintiff was very proud of his moving-picture exhibit. In actual practice, it is known that the changing of the quantity of oil and of the kind of oil does have instantaneous effects, varying with the kind of ore that is being treated, but to us the whole argument is stultified by the fact that flotation has been performed on a working-scale while using an amount of oil ranging from tons to nothing, from the old Elmore process to that of Wood. It is the air that is the prime agent; the bubbles, not the oil. Bubbles can be made without oil; they can be made by using any one out of a thousand forms of hydro carbon that will modify the surface tension of water and promote selective floatability as between valuable mineral and valueless gangue. The weeds of the desert are as effective for that purpose as the oleic acid that perplexed Lord Haldane in the British court of last resort. Judge Bradford does not dwell on the fact that in any industrial operation the first requisite is to economize and that economy will necessarily lead to the use of the smallest possible proportion of any reagent as soon as the operation is conducted on a scale large enough to make cost an item of importance.

Another feature of the Wilmington decision is the validity assigned to patent 962,678, covering the use of a soluble 'mineral-frothing' agent—an idiomatic term, for it indicates an agent that makes a mineral froth, but it is intended to mean a substance that will make a froth capable of floating minute particles of mineral. This method, or phase of the flotation process, does not involve the use of 'oil,' but it does include the use of acid. Judge Bradford recognizes that frothing agents had

been used previously in ore concentration, "but not in the absence of an oily ingredient." Immediately after saying this he makes the significant remark: "Even were the grounds on which the validity of the patent can be sustained less clear, it should have the benefit of the presumption of validity arising from the grant of letters." We submit that such presumption is not customary because patents are granted notoriously on a showing so inadequate to prove invention that the validity of a patent has to be decided not by the Patent-Office but by the Courts of Law. No specific proportion of the frothing agent is mentioned in patent 962,678, therefore somebody ought forthwith to patent the use of, say, 0.1% or one-tenth of one per cent of a soluble frothing agent and proceed to invalidate patent No. 962,678, which otherwise will be a further hindrance to the free operation of the flotation process. We expect to see oil discarded in the near future in favor of some cheaper modifying agent, and we would like to see this great metallurgical process freed from litigation, embargo, and imposition. For such freedom we look to the Supreme Court, not because we wish to deny to Minerals Separation any revenue that may rightly belong to that proprietary but because we believe that to Frank Elmore and Alcide Froment the miner owes the greatest process of concentration as yet devised by man. We have read the testimony given in the various trials and other records covering the obscure story of the flotation process from its lame beginning to its triumphant demonstration. From a reading of this evidence we conclude that Alcide Froment became interested in the subject through seeing the Elmore bulk-oil method at the Traversella mine, in Italy, and that his subsequent modification, introducing "gas of any kind" into an oiled pulp, was the link between the bulk-oil and the frothing process, not the miserable granulation method of Cattermole, that wretched failure from which the Minerals Separation people claim to have found their way to successful froth-flotation. The elaborate story of the directions given to Mr. Higgins, by which he rang the changes on varying proportions of oil, acid, water, temperature, and so forth, has never impressed us as a convincing explanation of the jump from the sinking granules of Cattermole to the floating froth of \$35,120. That Minerals Separation should have been the proprietors of Cattermole's American patent and that their purchase of Froment's British patent gave them no rights in America is a coincidence that it requires no psychologist to appreciate. Moreover, after Froment, but before Sulman, Picard, and Ballot's chief patent, came Elmore's vacuum patent, in which the use of air, with oil, was introduced. This patent and No. \$35,120 have never yet looked horns. The litigation between Elmore and Minerals Separation has been based on the old bulk-oil process, not the later air method. The American rights to Elmore's vacuum-oil process were acquired last year by a syndicate associated with the Miami, Ray, and other big copper companies. That issue remains to be tried. We see no end to the litigation.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Prospects and Prospector

The Editor:

Sir—Having read with a great deal of interest the articles relative to 'Speculation in Mines,' 'Prospecting,' 'Financing Mining Operations,' etc., printed in the MINING AND SCIENTIFIC PRESS during the past several months, and appreciating the fact that such discussion can only result in a beneficial influence if continued in a frank and courteous manner, I offer some ideas and conclusions resulting from my experience. Before proceeding further, I wish to state that I have no "chronic prejudice" toward either the prospector, the engineer, or the investor, for a narrow-minded attitude of one toward the other is to be deplored. There are intelligent prospectors as well as intelligent engineers and investors.

The present-day attitude of the prospector toward the engineer and investor is largely due to the fact that the engineer examining prospects does not, or will not, advise his employer to assume any of the risk of exploiting the prospect, but does not hesitate to intimate to the owner of the prospect that he is expected to do so. Again, the engineer may spend a day, a week, or longer, examining a prospect and then try to tell the owner things that he already knows are not true, from his own experience in carrying on the development of his own prospect extending over a period of one to ten years.

The average engineer falls short of the standard the prospector is justified in expecting of him, especially if he is a graduate of a mining college. His inability to say what will occur in future development, and in many instances to see or grasp the indications present in prospect-work or on the surface (usually clear to the prospector's practised eye, especially if he has spent much time in the locality) causes the prospector to wonder how the engineer has profited from his technical learning. It does not take much of an engineer to tell what has happened or whether the mine is worth the price asked after it has been developed with shafts, tunnels, drifts, cross-cuts, raises, etc., of sufficient depth and extent to prove the mine. Engineers should realize and appreciate these matters.

How many engineers examining prospects today for investors could or would have expended the same work, time, or money; or who have the actual ability even to have found many of the orebodies they are judging? A 'trace' means nothing to many engineers, yet practically every or body throws a trace by which it may be found, and in many cases it is all the prospector has to guide

him in his discovery of what may or may not be a valuable mine.

The prospector can judge from panning the surface dirt whether the 'trace,' if there is one, is worth following, whether it is likely to have come from a vein, a pocket, or a tale or clay seam, and the length of ore-shoot on the surface; in many instances he can also tell what the walls will probably be and the strike of the vein, the character of the ore, about how far it is to whatever is "throwing the trace." In addition, his observation is much keener than the engineer's, the slightest change of formation as indicated on the surface or underground does not escape his observation. This, of course, is only natural as he is constantly watching. This ability should also be realized and appreciated by the engineer, as it is from these hints that mines are discovered.

Regarding the sale of prospects, I do not agree with some of your correspondents that "an engineer cannot be too cautious." I do, however, think an engineer should exercise sound judgment, backed by experience, and protect his employers in every way that is fair and legitimate. There should be just as much responsibility, however, in turning down a prospect as there is in recommending one, but such is not the case; an engineer may fail to fulfill his duty to his employer and the mining industry by turning down a prospect, with little fear of reprimand, as he is only held accountable for those he recommends.

Nine out of ten prospects are turned down in the engineer's mind before he leaves the office (I also have been guilty of such an indiscretion), so that the gossip of the local 'knockers' club' may fit well with the engineer's prejudiced opinion. Anybody can turn down a prospect; it takes nerve to recommend one.

While it is contended by some of your correspondents that probably less than 1% of the prospects prove to be mines, I have not found such to be the case; nor do I believe such is the case provided 'boom camps' are eliminated (as they should be in such a summary) and only intelligent and legitimate prospecting taken into consideration. No intelligent prospector would waste the trouble, time, and development necessary to make a prospect worthy of examination unless it is, to say the least, encouraging.

Some prospectors, engineers, and investors should be digging potatoes or raising a garden rather than trying to enter the mining business, or, in other words, they are not what they claim to be. A man engaged in the

the revolving cathode, a drum covered with sheet-copper revolving in a bath of mercury about $1\frac{1}{2}$ inches deep, connected with the negative pole of the dynamo. The earliest style of cathode roller was ratchet shaped, with strips of copper fastened to it with screws. *F* is the earliest type of anode, which consisted simply of sheets of iron connected with the positive pole of the generator and suspended above the cathode. *D* is a shaking

rollers when the machine was shut-down, the electrolytic cells being out of use during the time employed in filling and discharging the tank; it was also found impracticable to keep up continuous agitation and carry on precipitation at one operation in the arrangement shown in Fig. 1.

After various experiments the arrangement shown in Fig. 2 was evolved, which was very satisfactory and quite a metallurgical success. It was substantially the arrangement of the Garvin plant as installed in the St. Paul mill in Sonora, Mexico. This was one of the most efficient silver-cyanide plants of its size and time. There were three agitators *A*, one settling-cone *B*, six precipitating-cells *D*, two battery-solution tanks *E*, and three sand-agitating pumps *F*. *G* is the solution-pump. Of course, their agitator was too expensive in pump-wear and power-consumption to compete with such modern devices as the Pachuca or Trent or Dorr machines of the present day. Their precipitating device is the only thing of any interest now.

If such a machine were operated along with a modern

copper plate arranged in steps, the flat part of the steps being connected with the negative wiring as a cathode, while the drop between steps had iron strips connected with the positive pole as an anode. The pulp and solution flowed over this in the process of agitation. This arrangement was all right on the black-sand machine on the Snake river, but generally there was such a scouring that it was eventually abandoned. No particular benefit was obtained by the electric connections on the amalgamating device. *E* is the centrifugal pump that agitated the charge, by pumping the material from the bottom of the cone-tank, mixed with the thin barren solution from the precipitating-cells which was pumped back into the top of the tank and thus kept in circulation. The aim was to keep agitation and precipitation going on at the same time, so that when extraction was complete, precipitation was also finished; then the charge would be allowed to settle, the solution and one wash-water would be decanted and then the pulp was discharged through the bottom.

This arrangement worked very well in the small machines in the test-plants, but in practice on a working scale various objections developed. The ends of the anodes would corrode and their renewal meant a considerable waste of iron, so the design was changed to that shown in Fig. 3. *A* on Fig. 3 was the final form of anode used by the Garvin people. They also had trouble from mud collecting in the boxes and sticking to the

Trent displacing-machine, a Vandercook filter, or a Dorr continuous decanting process, it would no doubt be a great success. Fig. 3 illustrates their best form of precipitating-cell. *A* is the anode, which also acts as a baffle, forcing the solution between anodes *A*, and *D* the

Fig. 2. A later Garvin flow-sheet. *A* is the agitator; *B* is the settling and clarifying cone; *C* is 6 electrolytic cells in series in a cement box or tray; *D* is the sump; *E* is the battery-solution tank; *F* is the agitation-pump; *G* is the solution-pump. This was built in 1907.

Fig. 3. The last and best type of Garvin cell arrangement in a shallow cement vat. *A* is the anode; *B* is the buss-bar transmitting positive current from generator; *C* is a cup of mercury by which positive wire from anode is connected; *D* is cathode roller revolving 20 r.p.m.; *E* is a brass wheel revolving in the mercury cup *F* and connecting (by negative wire *H*) the cathode with the generator; *G* is a mercury bath; *J* is cement bottom; *K* is solution inlet; *L* is solution outlet.

cathode. The anodes employed in all the working-plants were of iron, though some experimental work was done with peroxidized lead anodes at the testing-plants and it was expected to adopt them in the larger plants shortly. *B* is a buss-bar connecting the anodes with the positive pole of the generator. *C* is a cup of mercury on the buss-bar, in which wires connected with the anodes are inserted, making a quick and positive connection. *D* is the cathodic roller with a surface of sheet-copper, revolving in a mercury bath, *G* presenting a fresh clean surface to the precipitating field at each revolution. *E* is a brass wheel on the roller-shaft, which revolves in the mercury-cup *F*, connected with the negative wire *H*. *J* is the box in which the cell operates. They were about 5 ft. long and large enough for a roller 18 in. diam. Those built of portland cement, after the manner of laundry-trays, gave best results. *K* is the solution inlet, *L* the solution outlet, and *M* the hydrogen escape. Precipitation took place as readily when the solution was muddy as when it was clear, so long as it did not choke the box. With rich solutions amalgam accumulated on the roller in ridges; with lean solutions it washed off into the mercury bath as fast as formed.

When any considerable quantity of sulphide concentrate accumulated in the precipitating-cell, it tended to sicken the quicksilver, so it was better to partly clarify the solutions before the concentrate entered the field. Ten volts and one ampere per square foot of anode surface proved to be the most satisfactory current to use. The assay results are not now at hand, but I remember distinctly that with the six standard cells in series, there was no trouble in precipitating 75 tons daily of \$3 solution, so that the tailing would assay below 20 cents.

The clean-up was an easy matter. The current was shut-off. The solution was replaced with water, which was heated to boiling with live steam, while the roller was set in motion, and most of the amalgam would come off into the mercury-bath. The mercury would be drawn out and allowed to stand a few hours; then it was squeezed through a chamois skin; the drum was scraped with a rubber, the amalgam retorted, and the sponge melted into bricks. Low voltage generators built by the Crocker-Wheeler Co. were used.

When we were working the Garvin precipitating process, we were learning all we could of the results obtained by other electrolytic processes. It was observed that we were doing the work with not over one-tenth of the metal electrode surface as employed by either the Siemens & Halske or Butters processes. It was at first thought that the difference was due to the new mercury coating deposited on the revolving cathode at each revolution, making a fresh bright surface, but it seems more probable that the mere revolving of the drum presented the same surface many times to the solution and was thus equivalent to many times larger cathode surface; and it is pretty generally agreed that the rate of precipitation is largely dependent on the number of times the electrolyzed solution is washed past the cathode independent of the anode, the only function of which is to transmit the

current. The Garvin revolving drum moved in an opposite direction to the flow of the solution, making conditions for rapid deposition still more favorable.

When these experiments were commenced in 1904 it was thought necessary to increase the cyanide strength of solution to 3 pounds KCN per ton before sending it to the zinc-boxes in order to accomplish a satisfactory precipitation, even though a 1-lb. solution was sufficient to extract the precious metals. No one was making much of a success then in treating slime. The arm-agitator was the best thing that had then appeared. Under such conditions, such a method as has been described would be attractive in many places. But after the situation had cleared, following the 1907 panic, when the directors of the company sought to revive it, it did not appear to me a desirable thing to invest money in, for the Pachua, the Dorr, and the Trent agitators were firmly established. The Moore filter, the Merrill press, and the Butters plants were a success on slime-treatment, and the zinc-lead couple had overcome most of the precipitation troubles. Most of the relatively small operators with whom I was associated had little interest in a process that could only offer precipitation at an equal cost, particularly as it called for a large initial outlay in copper, mercury, and electrical equipment which would require skilled operatives on each shift. With the cost of zinc precipitation doubled, all this is changed. I believe, though, that anyone interested in electrolytic precipitation who does not recognize the importance of a moving cathode is overlooking a good bet.

Dolomi, Alaska, September 23.

Pipe-Capacity

The Editor:

Sir: In "Concentrates" in your issue of September 30, you stated "doubling the diameter of a pipe increases its capacity four times."

The accuracy of this statement is governed by what the Editor wishes us to understand by 'capacity.' As an admirer of the editor's advocacy of precision in expression I assume that 'capacity' as used is intended to be the capacity of a pipe to carry or discharge water, and not its capacity as a container or reservoir. It requires only a little reflection to understand that one 4-inch pipe will carry more water than four 2-inch pipes, because although the area of one 4-inch pipe is exactly equal to that of four 2-inch pipes, the amount of metal in contact with the water in the four 2-inch pipes is exactly double that of the one 4-inch pipe. The circumference of four 2 inch pipes is 25.1328 inches and of one 4 inch pipe 12.5664 inches. This reduces the friction in the 4 inch pipe.

As a general statement the carrying capacity of pipes, other conditions being equal, varies as the 2½ power of the diameter; therefore, doubling the diameter of your pipe increases its capacity 5.657 times instead of four times.

R. D. PERKINS.

Los Angeles, October 11.

A Graphic Method for Correcting Steel Tapes

By Walter Scott Weeks

*The errors that occur in measurements with a steel tape are due to four causes:

- (1) Stretching due to tension, induced by pull.
- (2) Shortening, due to the sag of the tape.
- (3) Variation in temperature from a standard at which the tape is correct in length when no pull is exerted.
- (4) Poor manipulation.

It is the purpose of this paper to develop a method by which the work of calculation of the errors of the first three types may be reduced to a minimum.

THE PROBLEM. The tape is often used horizontally, and the distance measured in multiples of 100 feet. Rather more complicated taping is done in mine-work. The measurements are taken from the head of the instrument along the line of sight to some definite point. The tape in use may be of any length and it may be at any angle with the horizontal. These facts prescribe that the system of correction, if it is to be comprehensive, must embrace the conditions of any length of tape and any angle of inclination.

It is the custom to hold the portion of the tape that is at the sighted point at the nearest foot-mark and to read the fractions of a foot at the instrument. The spring-balance that measures the tension must be attached to the ring on the tape at the instrument. This fact demands that the tension shall be measured at either the lower or the upper end of an inclined tape, for sometimes the shots will be inclined downward and sometimes upward. The tape must be standardized at some particular pull and temperature, and this standardization must be taken into consideration.

In order that the field-work may not be complicated, the requirement should be made that on any particular tape only one pull shall be exerted under all conditions.

The problem may be stated in another way:

A tape is sent to the Bureau of Standards and standardized. The tape is used in the field with a certain computed pull and the temperature is noted.

A chart is to be constructed from which can be taken in one operation the combined errors in the measured distance due to any cause whatsoever.

PULL. The pull to be exerted on the tape shall be 2000 times the weight of the tape per foot. This pull will hereafter be designated as the 'working pull.'

LIMIT OF ACCURACY. The method of making the correction will now be developed, and it will be seen that the correction will be given with an error not greater than 0.01 ft. The corrections will apply to any length of steel tape up to 200 ft. The corrections are com-

puted for steel having a density of 0.283 lb. per cubic inch, a modulus of elasticity of 29,000,000 lb. per square inch, and a coefficient of linear expansion of 0.0000065 per degree Fahrenheit.

STRETCH. The formula for the stretch of a horizontal tape is

$$e = \frac{P L}{S E}$$

P = pull in pounds

L = length of the tape in feet

S = area of cross-section of tape in square inches

E = modulus of elasticity = 29,000,000

e = elongation in feet

Let W = weight of 1 foot of tape.

Let w = weight per cubic inch of tape metal = 0.283 lb.

If the working pull is substituted in the formula it becomes

$$e = \frac{2000 W L}{S E}$$

$$W = 12 \times S \times 0.283$$

$$e = \frac{2000 \times 12 \times S \times 0.283 \times L}{S \times E} = 0.000234 L$$

$$e = 0.000234 L$$

This is the stretch when the working pull is exerted on a horizontal tape. It is now necessary to investigate the effect of the weight of the tape on the stretch when the tape is inclined.

Obviously the weight of the tape will exert its maximum effect when 200 ft. are in use and the tape is hanging vertically. The stretch then due to the weight is

$$e = \frac{T L}{2 S E}$$

where T is the weight of the tape in use.

Substitute for T the value $L \times S \times 0.283 \times 12$:

$$e = \frac{S \times 0.283 \times L^2 \times 12}{2 \times S \times E} = 0.00234 \text{ ft., when } L = 200$$

The effect of the weight of the tape will always be less than this because the tape will be inclined at a less angle. Hence we may say that as far as the stretch correction is concerned the pull may be measured at either the upper or the lower end of the tape.

The straight line may now be drawn that represents the equation

$$e = 0.000234 L \text{ (see chart)}$$

The ordinates show the error caused by stretch for all lengths and inclinations of the tape.

SAG. Professor E. V. Huntington of Harvard University has developed a method for computing the length of the chord of the catenary curve assumed by a tape that is supported at the ends.* The formula and a portion of the table are herewith printed.

*This article will also appear in the University of California publications in engineering.

*L. S. Marks, 'Mechanical Engineers' Handbook,' p. 150.

NOMENCLATURE:

 θ = inclination of tape W = weight of tape per unit of length L = length of tape in use P = tension at upper end k = correction factor given by table corresponding to any given values of θ and n

$$n = \frac{WL}{P}$$

Length of chord = $L - kL$ PORTION OF TABLE FOR DETERMINING VALUES OF k

θ	n	0.05	0.07	0.08	0.09	0.10	0.11	0.12
9	0.000150	0.000204	0.000265	0.000337	0.000417	0.000505	0.000601	
19	147	209	262	323	412	509	596	
29	135	185	242	307	381	463	551	
39	116	158	208	265	329	401	480	
49	91	125	165	210	261	318	382	
59	65	90	118	150	186	226	272	
69	39	54	71	91	114	139	167	
79	19	26	34	43	53	65	78	
89	5	6	8	10	13	16	20	
99	0	0	0	0	0	0	0	

If we substitute for P the value of the working pull, the sag formula becomes simplified:

$$n = \frac{WL}{P} = \frac{WL}{2000W} = \frac{L}{2000}$$

Different values of L may now be substituted and the correction kL plotted for different inclinations of the tape. The ordinates of the curves show the error caused by sag for various lengths and inclinations of the tape.

When the working pull is exerted at the upper end of an inclined tape

$$n_1 = \frac{L}{2000}$$

when n_1 represents the value of n under this condition.

When the working pull is exerted at the lower end with a length of tape L in use and angle of inclination θ , the pull at the upper end will be $W(2000 + L \sin \theta)$, and

$$n_2 = \frac{L}{2000 + L \sin \theta}$$

where n_2 similarly represents the value of n under this condition.

The greater the difference in n in these two cases the greater will be the difference in the length of the chords with a constant angle of inclination, as is exhibited in the preceding table.

Change

$$\frac{L_2}{2000} \text{ to the form } \frac{1}{2000} \frac{L_2}{L_1}$$

and

$$\frac{L_1}{2000 + L_1 \sin \theta} \text{ to the form } \frac{1}{2000} \frac{1}{1 + \frac{L_1 \sin \theta}{2000}}$$

Hence

$$n_1 - n_2 = \frac{1}{2000} - \frac{1}{2000} \frac{1}{1 + \frac{L_1 \sin \theta}{2000}}$$

L_1 varies from 0 to 200 and $\sin \theta$ from 0 to 1. Hence for a given θ the two fractions in the right and denominator have a maximum difference when L_1 is a maximum, namely, 200 in value.

Therefore, with a length of tape 200 ft. assumed, if the difference in the chord lengths is calculated it is found as the angle of inclination is varied that at $\theta = 0$ the difference is zero, because the pull at both ends is the

same. With increasing angle the difference gradually rises to 0.006 ft. and then declines again and becomes zero at 90° , because at that point there is no sag. Thus within the limit of error, which has been established, it makes no difference whether the pull is measured at the upper or the lower end.

There still remains to consider the standardization of the tape and the variation in length due to changes of temperature.

STANDARDIZATION. The tape will be standardized supported throughout its entire length at a temperature T and a pull P . The length of the tape will then be calculated with no pull and under the above conditions of support and temperature. The temperature at which the tape is exactly correct in length with no pull and entirely supported will next be computed. This temperature is called the standard temperature for the tape. An example will illustrate the method of computing the standard temperature.

A 200-ft. tape is standardized at a pull of 10 lb. and 60° F. and found to measure 200.06 feet.

First. What will be the length at 60° F. with no pull?

Let W = weight of the tape per foot. When the working pull is exerted the pull = $2000W$. The stretch is directly proportional to the pull. Hence when a 10-lb. pull is exerted the stretch is

$$\frac{10}{2000W} \times \text{stretch with working pull}$$

The stretch with working pull may be taken directly from the chart and for this case is seen to be 0.047.

If the tape weighs 0.01 lb. per foot, the elongation due to 10-lb. pull is

$$\frac{10}{20} \times 0.047 = 0.024$$

Hence with no pull the length would be 200.036.

Second. At what temperature would the tape measure 200 ft. exactly?

The coefficient of expansion for steel is about 0.0000065 for 1° F. Two hundred feet will shorten 0.0013 ft. with a drop in temperature of 1° F.

To shorten the tape 0.036 ft. the temperature must be lowered

$$\frac{0.036}{0.0013} = 28$$

$$60 - 28 = 32$$

Thirty-two degrees is then the temperature at which the tape is correct in length with no pull and entirely supported.

For this particular tape 32° F. is the standard temperature and is represented on the chart as 0.

TEMPERATURE VARIATION. The variations in the length of the tape due to variations in the temperature from the standard temperature are plotted with the stretch line as the datum. The temperature lines are marked with the number of degrees by which they differ from the standard temperature. If the standard temperature be subtracted algebraically from the temperature at which the tape is used the variation in temperature will be given. The variation in length = length in use $\times 0.0000065$ variation in temperature. The

difference between the ordinate of a temperature line and the ordinate of the stretch line for a given length of tape gives the variation in length due to temperature.

METHOD OF USING THE CHART.
An example will now illustrate the method of using the chart.

A tape whose standard temperature is 32° F. is used when the temperature is 62° F. the angle of inclination is 60° , and the length in use is 160 feet.

The temperature is 30° higher than the standard. Place one point of a pair of dividers on the intersection of the temperature line marked $+30$ and the vertical 'feet' line marked 160. Place the other end of the dividers on the intersection of the sag curve marked 60° and the vertical 'feet' line marked 160. Transfer this distance to the vertical scale at the left where the correction is read. It is seen to be 0.057.

If the temperature line is above the sag line, the correction must be added. If the sag line is above the temperature line, the correction must be subtracted. This results from the fact that when the tape is too long the recorded distance is too small and when the tape is too short the recorded distance is too large.

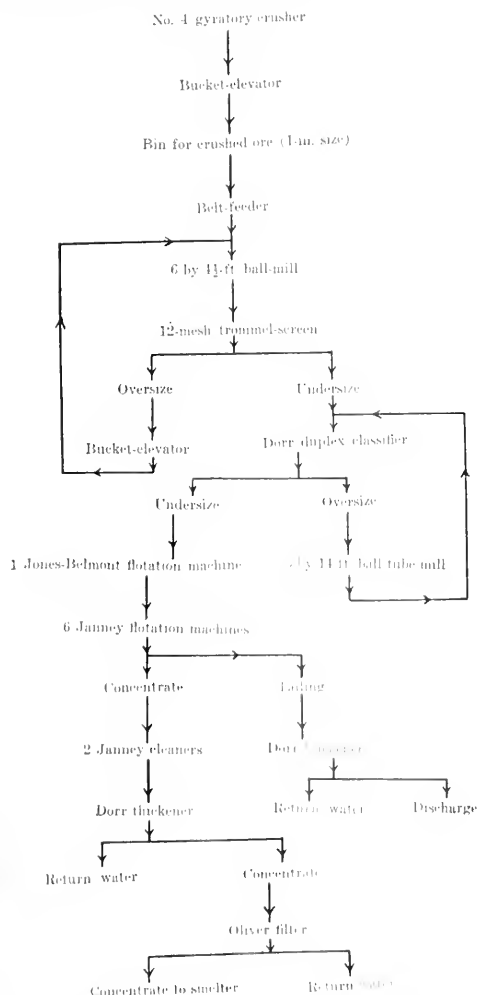

In the present instance, 0.057 must be added.

SUMMARY OF METHOD. Compute the temperature at which the tape is correct in length with no pull and entirely supported. This is the standard temperature. Use the tape with a pull which equals 2000 times its weight per foot. Subtract algebraically the standard temperature from the temperature at which the tape is used to obtain the "variation from standard temperature." Place one point of a pair of dividers on the intersection of the temperature line and the length line and the other point on the intersection of the sag line and the length line, and transfer this distance to the scale at the left where the correction is read in feet.

Flotation at the Florence-Goldfield Mill

By H. B. Clapp

The Florence mine at Goldfield, Nevada, was equipped in 1909 with a 40-stamp mill and cyanide plant, which was burned in 1912. Since then the mine has been operated for a small tonnage of shipping ore, during the extraction of which a considerable quantity of low-grade gold-copper ore was developed. Flotation has made its local treatment profitable, and a mill to treat the ore is giving satisfactory results from the following scheme of treatment:

The average extraction is 90% on a comparatively low-grade ore containing gold, silver, and copper.

*Mill manager.

The Jones-Behnmont machine, which works ahead of the six Janney machines, is a new type on the market, having been designed and patented by A. H. Jones of the Tonopah Behnmont Development Co. This standard-sized cell was installed in the Florence flotation plant at the request of Mr. Jones, in order that full data might be obtained under regular working conditions in comparison with the standard Janney apparatus. The Jones-Behnmont has been taking the whole mill-feed of from 150 to 180 tons, and has made a higher-grade concentrate, with a lower silica-content, than the shipping concentrate taken from the two Janney machines, which clean the rougher concentrate from the six Janney machines that make a rougher concentrate. The new machine not only requires less power, but also less labor, and less oil per ton of ore to make a better extraction. The company is considering installing this type of machine in the flotation end of the mill.

Nickel-Steel

The span of the Quebec bridge that was lost during September contained 5200 tons of nickel-steel. The loss is estimated at \$600,000. This material is a decided specialty when compared with ordinary carbon-steel. In fixing a price for nickel-steel the rule is to add \$12.50 per ton for each 1% of nickel added. This must be open-hearth. The standard specifications of the American Society for Testing Materials for structural nickel-steel and rivet nickel-steel say that the nickel shall not be under 3.25%. Steel firms usually like to get about \$12 for fabricating and \$12 for erection, but the charges for this work are governed to a great extent by competition, etc. Erecting in an out-of-the-way place would command a higher figure. The fabrication and erecting costs, of course, are added to the mill price of the steel. Freight must be calculated also. Structural steel today, that is, shapes, is around 2.75c. per lb., Pittsburg. Plates are quoted at 4c., and bars at 2.75c. Prompt deliveries command premiums. The material which went into the Quebec bridge was bought at lower prices than prevail today. The Memphis bridge over the Mississippi was constructed of Mayari steel, a natural nickel-chrome steel.

THE chemical difference between sodium and potassium nitrate is in the character of the basic metal. As indicated in the names of these compounds, the metal in the one is sodium and in the other, potassium. Sodium nitrate, or Chile salt-peter, is imported into this country in large quantity from Chile. The potassium or potash nitrate has come chiefly from Germany, which controls the world's potash supply. It is practically impossible to obtain potash salts of any kind at the present time and quotations on potassium nitrate (niter) have not been published for a long time. Owing to the great demand for Chile salt-peter the price of this commodity has greatly increased and it is now bringing approximately \$1 per 100 pounds.

THE SMELTER.

THE OLD CONVERTERS AND THE NEW.

The Naltagua Smelter

By Mark R. Lamb

Experiments were made some time ago at Gatico to determine the possibility of converting matte in small acid converters, by lining them with basic brick. George W. Waters made a success of this, and it tempted others to make the trial. The manager at Naltagua decided that it was economy to use the basic converter designed by Pierce & Smith, but meantime he experimented with their smaller acid converters provided with basic brick lining. In this plant, the acid lining had given much trouble, on account of the difficulty of finding lining material at all suitable. The results attained with the acid converters with basic lining, although not as satisfactory as those obtained with the converter designed specially for the process, were an improvement over former practice, and these furnaces are still being operated basic, until the installation of the Pierce & Smith converter is completed.

The smelter makes about 15 tons of copper per day, and at the present high price of that metal, is making handsome profits. The sudden rise in the price of coke decided the management to install reverberatory furnaces to burn pulverized coal, since the Chilean coal is of a good quality and there is no great demand for slack. These furnaces have been on order some weeks and are beginning to arrive. Foundations are being prepared and it is expected that they will be blown-in within six months. This period seems long, compared with the time required for such installations elsewhere, but Chile is a long way from the machinery factory, and labor is none too abundant and is unskilled in such work.

The new plant is complete in every detail: it includes a drier, pulverizer, and ball-mill for reducing the coal to 150-mesh and finer. The ore also must be dried, and will be crushed to a fineness depending on the relative price of coal and coke; in other words, with cheap coke, it

will pay best to send as much as possible of the ore to the blast-furnace, whereas when coal is relatively cheaper than coke, the crushing will be finer, and a larger proportion of ore sent to the reverberatories.

It is expected to obtain a smelting ratio of seven of ore to one of coal. The pulverized coal will not be stored in large quantities, in order to avoid the danger of spontaneous combustion in the bins. Both the coal and the ore will be dried to under 2% moisture, in order to reduce fuel consumption in the reverberatory furnaces.

The plant is so arranged that the matte from the water-jacketed furnaces will be laundered direct from the fore-hearths to the converters, while the matte from the reverberatories will be hauled by an electric locomotive to within reach of the converter-crane and thus charged into the converters. It is planned to take the slag away intermittently in cars, but when water is plentiful, this slag will probably be granulated. Formerly, and until the available space was all filled up, it was the practice to granulate the slag from the water-jacket furnaces, but it has been found necessary to resort to cars, mules, and boys.

When the new furnaces are in operation, smelting with the cheapest fuel available and with cheap power from waste gases, using the Pierce & Smith converter, this plant will be completely up-to-date and will smelt at as low a figure as any plant in South America.

THE LARGEST STEEL CHIMNEY in the world is that at the United Verde Copper Co.'s smelter at Clarkdale, Arizona. The stack is 400 ft. 1 in. high, 30 ft. 9½ in. diam., and is lined with 4 in. of brick throughout.

TUNGSTEN ORE is being mined near the Miramichi river in New Brunswick. A 20-ton mill is at work.

The Wet Treatment of Copper Concentrate

By Lawrence Addicks

*A complete wet process† consists of roasting and leaching the calcine in dilute sulphuric acid produced from the roaster-gases, roasting the residue with salt, and leaching with dilute tower-liquors (the well-known Longmaid-Henderson process) and recovering the copper, silver, and gold by cementation or electrolysis or a combination of both. It is evident, however, that the residue from the first leaching, carrying about 20% of the copper and all of the silver and gold, can be smelted if preferable. In considering the application of the scheme to individual cases, it must be remembered that freight plays a large part in any reduction process wherein smelting is not conducted at the mouth of the mine, and that it is not practicable today to build small smelting-plants for individual operations.

The experiments may be grouped under four main heads: roasting, leaching, chloridizing residue, and recovery of copper solutions. The products of two concentrators were used: the Nacozari concentrate was the product of a large modern mill not using flotation, the copper mineral being largely chalcopyrite; and the Tyrone concentrate, the product of an experimental mill, including flotation, the copper mineral being chiefly chalcocite. Typical analyses would be as follows:

	Nacozari	Tyrone
Copper, per cent	14.0	14.0
Silver, ounces per ton	4.0	0.5
Gold, ounces per ton	0.01	Trace
Iron, per cent	31.0	28.0
Sulphur, per cent	34.0	30.0
Silica, per cent	13.0	...
Alumina, per cent	3.0	...
Lime	0.6	...

The Nacozari concentrate carries considerable coarse jig-product while the Tyrone material comes from an ore where the copper is finely disseminated and the quantity of 100-mesh is quite marked. The presence of the flotation-concentrate in the Tyrone material brings up the copper content of the fine.

ROASTING. The object in roasting is to make as much of the copper and as little of the iron as possible soluble in dilute sulphuric acid. The work is similar to roasting fine pyrite in sulphuric acid manufacture except that this solubility ratio rather than the complete utilization

of sulphur is the controlling factor. Small-scale work is not satisfactory as a guide to possible results because it is practically impossible to prevent over-heating due to rapid oxidation of sulphur in a laboratory experiment.

An 18-ft., water-cooled, six-hearth McDougall furnace was used, the speed of rotation being gradually cut down until 'dead roasting' conditions were obtained.

FIG. 1. NACOZARI CONCENTRATE ROASTED IN 18-FT. SIX-HEARTH FURNACE AND LEACHED IN 4% SULPHURIC ACID IN LABORATORY.

Greater tonnages could doubtless have been obtained in a seven-hearth furnace.

Many samples were taken from various hearths and the acid-soluble copper and iron determined by leaching with 1% sulphuric acid in the laboratory. It is evident that the chalcocite can be oxidized much more readily than the chalcopyrite, although size of particles has something to do with this. An investigation of the solubilities of the various sizes of particle was carried out by screening some of the calcine, as shown in Fig. 3. As would be expected, the finer particles are the more thoroughly oxidized; the jig-product in the Nacozari concentrate is one reason for the poorer results obtained in the treatment of this material.

In general, these large-scale experiments indicate the possibility of reasonably obtaining the results desired—high copper and low iron solubility—but it is obvious that the residue after leaching will contain sufficient copper to require re-treatment, aside from the fact that any silver and gold will remain in this residue.

LEACHING. As shown in the paper presented last year, such satisfactory results in the extraction of copper from firing were obtained by dumping the hot calcine from the furnace into a leaching-trough, the few

*Abstract of paper presented at the Arizona meeting of American Institute of Mining Engineers (September, 1916).

†Patent applied for.

seconds agitation thus obtained extracting almost as much copper as prolonged treatment in other apparatus, that the same idea was tried out with the concentrate calcine. It was not possible, for various reasons, to handle the output of the furnace directly, so the calcine was stored and then fed to a bucket-elevator which in turn delivered into a V-trough in which the leaching-liquor was flowing. The results were here disappointing, as although there was instant extraction of perhaps half of the soluble copper, a prolongation of the trough to

which would artificially increase the iron taken into solution.

give 60 sec. travel did not greatly increase this amount. It was definitely shown in the laboratory as well that prolonged agitation was necessary to extract all of the soluble copper. The leaching-trough delivered into an acid-proof drag consisting of an endless belt with angle rakes, of the type commonly used in concentrators for dewatering. This acted more or less as a classifier, the very fine residue being carried over with the liquor, from which it was subsequently separated by settling. As this still gave insufficient agitation to the sand, a Parral agitating-vat was tried, but it was found that the material was too heavy to yield readily to any sort of air-lift agitation. A Dorr classifier was then added to the apparatus and this did better. It was found, however, that it was necessary to pass the residue six or seven times through the leaching process in order to obtain an extraction equal to that shown by laboratory tests on the calcine.

The large-scale leaching tests were confined to the Tyrone material, a lot of 30 tons of calcine from some of the roasting tests being used. The first runs on a lot of 17 tons of not quite 'dead-roasted' material containing 4% sulphur gave results that were satisfactory except in that too much iron was dissolved, causing a needless consumption of acid and embarrassing any electrolytic scheme of recovery. Later, better-roasted material was available and a careful record kept of the metal balance and acid consumption.

These figures check reasonably close except in the case of iron; but it must be remembered that various iron parts in the apparatus used were attacked by the liquor,

The acid consumption was 2495 lb. of 100% sulphuric acid for the run. This is equivalent to 2.28 lb. of acid per pound of copper extracted. Laboratory tests on the same calcine indicated a consumption of 2.0 lb. The leaching was done at about 125° F. with 5.6% free acid in the liquor entering the trough. The residue was passed through the leaching process five times.

In general, when a 15% copper calcine is fed to the trough, the residue at the end of the trough will contain about 8% Cu, the extraction representing the instantaneously soluble copper. This residue can be brought down to about 3.5% Cu by suitable agitating means, with a consumption of a little over 2 lb. of acid per pound of copper, and with the extraction of but little

FIG. 3. RELATIVE SOLUBILITIES OF VARIOUS SIZED PARTICLES OF CALCINE.

iron. The final residue weighs about 60% of the original concentrate before roasting.

CHLORIDIZING RESIDUE. No large-scale work was done on the chloridizing of the residue from the first leaching. The analysis of this residue, however, differs from that of pyrite cinder, so long successfully treated by this process, only in the amount of silica present. Various small-scale experiments were tried and 50 lb. or so was sent for test to a plant where the Longmaid-Henderson

process was in operation. Both sets of experiments were entirely satisfactory.

A small lot of the leached residue was prepared for test. This contained 5.6% Cu, 1.9 oz. Ag, and 2.5% S. Raw concentrate for adjusting the sulphur-copper ratio was used, containing 14.4% Cu, 0.55 oz. Ag, and 31% S. Fig. 4 shows the extractions with varying percentages

FIG. 4. CHLORIDIZING LEACHED CONCENTRATE CALCINE.

Roasted $1\frac{1}{2}$ hr. at 975° F. with addition of salt and 10% raw concentrates.

Calclines: 5.6% copper, 1.9 oz. silver, and 2.5% sulphur.

Raw concentrates: 14.4% copper, 0.55 oz. silver, and 31% sulphur.

Liquor: 5% Na_2SO_4 , 5% NaCl , 5% FeCl_2 , and 0.5% $\text{HCl} + \text{H}_2\text{SO}_4$.

of common salt added to the 'mix' after roasting in an electric muffle furnace $1\frac{1}{2}$ hr. at 975° F. and leaching in a liquor carrying 5% Na_2SO_4 , 5% NaCl , 5% FeCl_2 , and

FIG. 5. EFFECT OF SULPHUR-COPPER RATIO UPON EXTRACTION. 7% SALT ADDED TO ROASTING 'MIX'.

0.5% $\text{HCl} + \text{H}_2\text{SO}_4$. Fig. 5 shows the effect of varying the sulphur ratio. The results show an extraction of 98% of the copper and 79% of the silver. The report on the lot of residue sent away fully confirmed these results.

RECOVERY OF COPPER FROM SOLUTIONS. The liquor from the chloridizing plant would doubtless be reduced to argentiferous copper-cement by iron. But 20% of the original copper is involved. The sulphate liquor from the first leach could be precipitated on iron if desired, or with certain limitations would be suitable for electrolytic deposition of the copper and regeneration of the acid. The concentrate carries from 1 to 2 lb. of sulphur per pound of copper, equivalent to from 3 to 6 lb. of 100% sulphuric acid, less process losses, if the roaster gas is oxidized to sulphuric acid. Since the leaching calls for but a little over 2 lb. of acid per pound of copper, plus tailing losses, it would seem possible, therefore, to figure on a simple cementation plant, considering electrolysis as a competitor on a basis of relative profit and not of necessity.

World's Record in Shaft-Sinking

The record was made in the month of August at the Chief Consolidated Mining Co.'s shaft at Homansville, Tintic district, Utah.

In 31 days the shaft was sunk a total distance of 261 feet.

The shaft consists of three compartments. The two hoisting compartments being 4 ft. 2 in. square inside measurements, and the third, or man-way, compartment 4 ft. 2 in. by 3 ft. 2 in. Timber used consisted of 8 by 8 in. for the sets and 2 by 12 lagging for the outside lining. The sets were spaced 6 ft. apart.

The rock was limestone lying in flat beds, some of which were quite hard and some soft.

The shaft was operated in three shifts of four machine-men each and a topman and engineer on each shift. On day-shift two timbermen did the timbering.

The Sullivan and Denver rock-drill sinking-machines were used. Two five-foot rounds of about 22 holes each were drilled per day.

The timbermen worked on what was termed a 'suspended bulkhead and shooting set,' consisting of a set of 8 by 8 in. timbers, the same size as the shaft sets, with $\frac{1}{4}$ in. sheet iron plates bolted on the bottom of the two outside compartments. This device was suspended on both ends by means of one-ton chain-blocks hung from two sets above, allowing the bulkhead to be lowered a sufficient distance from the bottom set to allow a new set of timbers to be put in place, without stopping the work of the machine-men and shovellers below. This arrangement added greatly to the safety and speed of sinking.

Hoisting was done through the centre compartment only, by means of two 15½-in. ft. buckets used alternately a chain hung from the head-frame. This chain was hooked into a ring on the bottom of the bucket, holding the bottom stationary and allowing it to tip on an incline door and chute, thereby discharging its contents.

Walter Fitch, Jr., was manager; J. D. Matheson, superintendent; and J. H. Santo, foreman.

Flotation

A Discussion Before the American Institute of Mining Engineers at Globe, Arizona, on September 21, 1916

THE CHAIRMAN (C. E. Mills): Gentlemen, the subject of this afternoon's session will be 'Flotation.' The first item on the program will be an abstract of Mr. Cole's paper, 'The Advent of Flotation in the Clifton-Morenci District, Arizona.'*

DAVID COLE: There is much kaolinized material in Morenci ores and a great deal of colloidal matter is developed in milling them. The Elmore process had been tried by the Detroit Copper Mining Co. some years before and had been defeated, it was reported, by the slime. This delayed the serious consideration of the flotation process in the district. After it was found that flotation would apply at Morenci, there were difficulties to overcome on account of the restriction of space in the mill-building, known as concentrator No. 6, of the Arizona Copper Company.

Morenci ores are heavy in sulphide minerals and have relatively low ratios of concentration—from 7 to 9 into 1. It is therefore economical to remove a large portion of the copper sulphides in primary roughing operations. After the removal of the easily separated coarser sulphide minerals, there remains a matrix similar to the disseminated 'porphyry' ores, requiring fine grinding to release the remaining sulphides. The grade of the material that reaches the re-grinding departments in Morenci practice is similar to that of the mill-feed of the 'porphyries,' and the process required below the roughing-out stage is substantially the same as that required in the large plants handling finely disseminated copper ores.

The re-grinding equipment adopted at the No. 6 concentrator of the Arizona Copper Co. consisted of twelve 8 by 3-ft. Hardinge mills. These used pebbles for both lining and grinding media, and occupied all the space available. The capacity of these mills for finished work was therefore the limiting feature as far as plant-capacity was concerned, and if the re-ground product was to be so limited in size by the degree of grinding required by the flotation machines then available, namely, to pass a 48-mesh screen, the capacity of the plant would be greatly reduced.

Therefore, when flotation was found to be amenable, it became desirable to develop a flotation machine that would not be clogged or embarrassed by the accumulation of oversize; that would afford a standard and completely effective treatment to the sizes in the re-ground product coming within the range of flotation; and a machine that would not be embarrassed by sizes too coarse for recovery in the froth. It was at once realized that on account of the complete removal of the slimed sul-

phides in the frothing operation, the pulp so treated would have been classified in a most desirable way to make the recovery of the remaining free sulphides relatively easy and complete.

In order to do this in the limited space afforded, the C-B flotation machine, described in my paper, was designed, constructed, and operated with the results given. Mr. Julius Bergman, working with me as mechanical engineer, assisted greatly in the detail work and development of the machine, and it was therefore christened the Cole-Bergman Frothing Classifier.

The spitzkasten type of machine, which is also illustrated and briefly described, has not as yet had a trial, but I have much confidence in its usefulness in certain situations. It differs from the C-B or stepped type, as those who have read the paper will note, by including in the flotation treatment or frothing operation the usual features of spitzkasten sizing.

With this piece of apparatus the ore will be taken direct from the ball-mill where it has been ground in the presence of the frothing reagents, and we hope and expect to get a good froth-concentrate over the top as usual, together with a coarse classification of the sand in the hopper of the spitzkasten nearest the intake of feed, and successively finer sand (within reasonable limits, of course) in the hopper following toward the discharge. The overflow rejected from the first of these machines will contain nothing too large for flotation; it can be re-treated and discharged to tailing, while the sand drawn from the hopper will be in good condition to make feed for the tables, which will readily remove the sulphide particles too large either to go over with the primary froth or to remain in suspension long enough to escape with the overflow, and thus receive another frothing treatment. The sand from the first frother after the table treatment can be returned to the grinding-mill for further reduction and complete re-treatment, or be discharged as waste, thus making a simple 'frothing first' flow-sheet.

I receive a good many inquiries from people who have heard of the C-B scheme of treatment, asking for laboratory sizes of the apparatus on which to test their ores, thus implying that there must be something about this method of treatment that will result in higher recovery than by the use of other types of apparatus. I can see no advantage in using small or laboratory sizes of the pneumatic types of flotation machines and have not made any attempt to provide a bench-size machine, and would not recommend it.

In testing ores by flotation in a laboratory it is necessary to have a good mixer as well as a good frother, and

*M. & S. P., October 14, 1916.

when the two can be combined as in the mechanical or impeller type (all of which seem to be a modification of the Hoover idea) this is the logical machine to use in the bench-work stage of the investigation. If good results are obtained with the impeller type in the laboratory, it is practically certain that better results can be obtained in the full-size unit in the mill, either with the impeller type or the less expensive pneumatic type, one of which I have attempted to describe in my paper.

RUDOLF GAHL. Since I wrote the paper on flotation† that is in your hands, important developments have taken place, and for this reason I shall try to bring it nearer to date by a few remarks.

You will have noticed that at the Inspiration concentrator, flotation is not entirely relied upon for the recovery of the coarser mineral particles, but that the flotation tailing is split on drag-belts into a sand and into a slime, the sand product being re-treated on tables. We have found that if we wanted to, we could leave out these tables and substitute flotation machines, as flotation machines will effect fully as good, if not a better, recovery on such deslimed material as tables, but a treatment of this kind would be more expensive in view of the fact that oils are required costing more than the oils that we are using now in our main flotation plant. For this reason, we are not considering making such a change. We have decided, however, to install flotation machines for the treatment of our table-middling, as on the middling product, which is of a somewhat higher grade than our present table-feed, a more expensive treatment seems justified.

I would also like to add a few remarks regarding the treatment of oxidized copper ore: Although our experience shows that hydrogen sulphide and other soluble sulphides will facilitate a good recovery of the copper carbonates in certain ores, we have not been able to prove that it would be advisable to adopt such a treatment for the ore mixture that is sent to our concentrator now, and have, therefore, looked toward leaching for recovering the oxidized copper now being lost.

It may interest you to hear that we figure on using limestone for the precipitation of the copper that will go into solutions. Small-scale experiments in this direction showed encouraging results. If the limestone precipitation will do what it seems to promise, it may develop into a novel feature of copper metallurgy.

FREDERICK LAYSE: The relative merits of the impeller and pneumatic types of flotation machines have been the subject of much discussion and the selection of type is doubtless dependent largely on local conditions and on the characteristics of the ore undergoing treatment. We have always been of the opinion at Anaconda that whenever a neutral or alkaline treatment was used and the oils could be added to the pulp going to the ball mills, the pneumatic type had an advantage both as regards power-consumption and installation cost. When, however, the treatment required the use of acid, as is the case on some copper ores and most zinc ores, the pneu-

matic machine loses much of its advantage. Obviously, the acid cannot be introduced into the ball-mill and it is generally necessary to add it ahead of, or at the same time as, the oil.

Thus it becomes necessary to insert an agitator between the ball-mill and the flotation-machine, the pneumatic treatment alone not being sufficiently vigorous. The early pneumatic-machine installations contained Pacheca tanks for this purpose. These, however, did not prove effective, for the reason that an emulsification of the oil is required and not merely agitation. It therefore becomes necessary to use an impeller or some form of mechanical emulsifier, and the power required to operate this machine must be added to the power consumed by the flotation-machines proper.

In Montana we find that our power consumption for emulsifying and flotation is about 0.24 hp. per ton as compared with 0.15 hp. for flotation alone at Inspiration. The capacity of an impeller machine is materially greater when the emulsification of the oil in the pulp is done in the ball-mill. In this connection an interesting suggestion was recently made by Dr. Cottrell. He suggests making an emulsion of oil and water in a special emulsifier, such as made by the De Laval people, consisting of two discs running almost in contact. The oil and water is fed at the centre and is thrown out at the circumference. Thus the work of spreading the oil through the pulp might be done more efficiently than is now the case.

For some time it seemed to us that the main point to be considered in choosing between the two types of machines was power and that this depended largely upon whether acid, neutral, or alkaline treatment were selected. Of late, however, it has seemed to us that the impeller type of machine has another advantage, which, I recall quite distinctly, was cited as a disadvantage when the first Callow machines were brought out. I refer to the toughness of the froth. Most of you doubtless recollect that one of the advantages of the pneumatic machines was supposed to be that the froth breaks down quite readily, thus rendering the mineral content of the froth easier of collection. It is becoming more evident to us, however, that this apparent advantage is actually the reverse, for the reason that the coarser mineral grains tend to fall back before they can be skimmed off and thus are lost or must be recovered by tabling. We are beginning to believe that the tougher froth is a distinct advantage of the impeller machine and our belief has been considerably strengthened lately by tests made on a disseminated copper ore from South America. It was impossible to make as lean a tailing on the pneumatic machine as on the impeller machines, owing to falling back of the coarser mineral grains.

FRANCIS S. SCHMERKA: Regarding the proposed scheme of Dr. Gahl's for precipitating the copper solution, I desire to call attention to the fact that the sulphate of lime precipitated from the solutions would lead to the necessity for smelting in the blast-furnace. Naturally, from the sulphate of lime, sulphides would be

formed. Now, I thought that Dr. Gahl by thickening the pulp would assist the leaching.

RUDOLF GAHL: I believe fully everything that Mr. Laist says, except his conclusions. His remarks regarding the relative hardness of the froth produced by the different types of flotation machines suggests that it might be worth while trying to modify the froth by reducing the air supply, and perhaps also by reducing the froth in the flotation mixture. I feel sure that the character of the froth can be modified to some extent, although I doubt very much if it ever would approximate the froth in the standard type of machine. Regarding Mr. Schimerka's remarks, I would like to say that I know little about smelting, and have not considered the smelting problem carefully. All I know is that Mr. Wallace, who used to be smelter superintendent of the International, assured me that he could smelt that stuff, and could pay for the lime also. Regarding the other point Mr. Schimerka brought out, about adding the acid to a thickened pulp, my impression is this, that a still larger part of the water-supply would be contaminated because we have to figure mainly on leaching very fine slime containing oxidized copper; and it is the experience of every mill-man that to settle this slime to any consistence it must exceed 3:1, that is, three parts of water to one part of solid. That would mean, if he added the acid to the thickened pulp, we would spoil three tons of water to each ton of leached ore.

DAVID COLE: Mr. Chairman, I understand that Dr. Ricketts 'turned down' Dr. Morse when advocating leaching processes for low-grade tailing by methods that involved first getting the copper into solution and then separating the solution from the pulp in a clarified condition, which is difficult and involves much washing with clear water, etc., resulting in thin solutions, the latter entailing 'miseries' in effecting precipitation and recovery of the metal. On the other hand, Dr. Ricketts approves the present process which Dr. Morse is using at Chino, in which the oxidized copper is first taken into solution by the use of about three pounds of sulphuric acid per pound of copper digested; this copper is then precipitated upon the iron in an agitated mass, which results in metallizing the copper at the expense of about two pounds of iron per pound of copper precipitated. The metallized copper is then in a fine state of division in the pulp, and the remaining copper sulphides that were not attacked by the acid are also in the pulp in a fine state, and the whole is subjected to flotation treatment for the removal of both the sulphide and metallized contents, thus doing away with the necessity for removing the solution in a clarified condition from the pulp under treatment, avoiding the washing of the pulp for complete removal of solutions pregnant with copper, and avoiding most of the 'miseries' previously unavoidable.

Miami has been experimenting for some time along the same line and has achieved success on a laboratory scale. Flotation has been used successfully in the separation of ultra-fine native copper in Michigan, and

there seems to be much promise in this new scheme of treatment for the recovery of copper in low-grade ores when in a mixed condition of oxide and sulphide.

I have read with very great interest Dr. Gahl's painstaking paper giving us the details of development of flotation at Inspiration. Prior to the use of flotation in concentration it had long been recognized that the 'unavoidable' loss of sulphide was in the slime inevitably produced in the grinding operations required to free the minerals. The classification of the feed prior to the final stage of treatment had long been in fashion, it assisted the sand-treatment machines and resulted in lowering the tailings made by them, but at the expense of the slime-treatment department; and while little was ever expected of the latter, the wisdom of complicating the process by hydraulic subdivisions was being seriously questioned. Indeed, at the time that gravity-method flow-sheets were being developed for Inspiration ore, there was a minor revolution impending through the improvement in table-practice and the elimination of the hydraulic classifier. This return to simplicity gave no promise of higher extraction, but it did promise a less complicated mill, smaller in size per unit of capacity, less costly to build and less expensive to operate, and that would do as well. Wholesale concentration in relatively small space would get as good results as piecemeal concentration had been getting in the multiple operations and spread-out plants of the disseminated copper mines.

The one great drawback was the slime. The desiderata of the engineer and manufacturer were to provide a grinder that would on one hand produce a minimum of slime, and improved devices on the other hand to recover as much as possible out of what was unavoidably made. The technical press reflected this state of things in the advertisements of the period. There was much revamping of old ideas with some refinement, but nothing new. Tube-mill grinders were taboo for concentration, because they had a bad reputation as slime-makers. Automatic canvas plants were being exploited and very ingenious multiple-deck table-devices were being offered as the "remedy"—the only one in sight.

Looking backward no farther than 1912, when the Inspiration was devising its milling methods, we now see that we were without effective resources in combating real slime. Mr. Callow's investigations[‡] apparently had demonstrated that some departure from the usual gravity practice would be advantageous and that a high recovery for that method would be possible on the granular material. There was nothing new to apply to the slime itself, and we now see that the departures were really of minor importance, fitting the time. This was the situation when the Inspiration company was endeavoring to evolve a scheme of milling.

After reviewing from every angle the results of experiments on the ore and other information available, a modified flow-sheet was finally crystallized by Mr. Burch and adopted by the management. Mill-plans were drawn for what was to be a most highly developed 7000-ton per

[‡]M. & S. P., May 29, 1915.

day gravity-process plant, and work was immediately started to carry out these plans. The mill-site was selected, and much active work had been done before flotation (by this time being hastily tried in the old experimental plant) had so far won its battle that results could be viewed as hopeful.

The apparent promise of flotation, however, was extremely attractive, because the process would be simple and would solve the all-important slime problem. The process would have a greatly reduced number of stages! The plant would be much smaller per unit of capacity! The cost of construction per unit of capacity would probably be very much less! The use of water would be minimized. Grinding would have to be carried farther than usual, and would be the main item of milling cost, but this was not a very great handicap because slining did not matter! What system of grinding would be best to use and which the best machine? Would it be possible to parallel the small test-mill results on a full tonnage, and finally would it not be too hazardous to accept so revolutionary a process with so many untried features?

The mine would produce about 600 tons daily of freshly broken ore directly from the headings. This happened to be the rated capacity of the full-sized Minerals Separation unit that the flotation people were urging as a means of improving their extraction. If this ore from the headings were put in stock pile in the usual way, pending the completion of the plant, the ore would oxidize to some extent and besides would involve reclaiming expense later on. Why not mill it as fast as produced, in an experimental mill, wherein not only flotation problems, but grinding problems, power consumption, use of water, preparation of sticky concentrates, and other vital questions could be definitely threshed out under what would be regular commercial conditions on full-sized machines! Thus these 'pilot' operations labor would be used economically, and production would almost, if not quite, pay all of the current expenses, except the mining cost.

This program was adopted. That the decision to carry it out was a wise one is shown in Dr. Gahl's and Mr. Burch's admirable papers, and that it paid its way is shown by Mr. Mills's annual report for 1915, in which he says: "Contrary to the usual experience, this test-mill paid the cost of its construction, its operation expense, the present average mining cost on ores treated, and something besides, and has been written off the books."

Thousands of dollars were spent by the company, by inventors, and by manufacturers in demonstrations. Expense was subordinated. Heavy shipments by express were made when necessary to hasten the work, and much more than flotation was developed.

Four different types of Symons crushers and pulverizers were tried. Three of these were marked and interesting departures from ordinary practice. The company had purchased the Hardinge patent rights for Arizona and four forms of this mill were installed to de-

termine the best form to use, and these were kept busy during nearly the whole campaign. A long parallel tube-mill was installed and run in competition with the Hardinge mills. A high speed Huntington type grinder was at one time a prime favorite. Hammer-pulverizers of two different makes were centres of interest for brief periods. Various linings and grades of flint were tried in the pebble-mills. Steel balls in place of pebbles were advocated and a carload purchased.

In the latter part of the testing period the Marcy type of ball-mill, especially designed for using iron balls larger than usual, and adapted to crush from breaker size to 48-mesh in closed circuit in one operation, was installed and perfected. This grinder proved capable of a greater range of reduction than had previously been thought possible, taking feed as coarse as 3-inch cubes. It is a ball mill pure and simple, having large capacity in small space. It makes use of a perforated diaphragm to keep the balls and charge inside of the mill until the latter will pass a $\frac{3}{8}$ -in. opening, and it has the equivalent of a peripheral discharge. An overflow-classifier determines the finished size and the oversize is continually returned to the grinding-chamber. This mill uses little water in the grinding-chamber, so that its charge of ore is mortar-like in consistence. It was quite successful. There was nothing in the Hardinge equipment to parallel it because the Hardinge mills were built for pebble-mills and did not have feed-scoops or openings adapted to handle as coarse a feed, and the linings would not stand up under a ball load. Would the Hardinge machines when built as a ball-mill with the required strength, with the same type of lining, same size of feed and discharge openings, do as well? To wait for a mill to be made over or a new one manufactured would take too long, so the Marcy type was adopted, and contrary to what I think is the popular impression, the conical type ball-mill did receive a trial at the Inspiration.

Electric recording instruments were installed in the test plant so that accurate power-records could be continually made while the various machines were being operated.

Several varieties of drag and rake classifiers and two types of vacuum filters were installed and records made. The efficiency of high reduction herringbone gears for driving ball and tube mills became a matter of interest on account of the troubles that developed in them, and the reasons for these troubles, which would make a paper by itself.

This testing work grew into a process of elimination; the scrap pile grew steadily; much of it is yet to be seen at a point below the present concentrator. Some blasted hopes may be buried there, but it does not follow that all of the machines or materials that were returned to the sponsor or that found their way to the 'bone-yard' were entirely unfit. It was necessary to choose and to discard and that there is no acrimony in connection with the matter speaks well for the justice and judgment that prevailed. Doubtless some discarded things might have

answered as well, but it would be hazardous indeed to say that anything vital on the score of cost or recovery failed to receive recognition in the final selection. One of my mental offspring was among the fallen. It held out for a long time and I greatly appreciate the favorable mention which Dr. Gahl has made of it.

Referring to the flow-sheet finally adopted, I note that hydraulic classification had no place in the 600-ton experiments that Dr. Gahl has described, and I note that he has not referred to the reason for retaining this remnant of the old system of concentration in the flow-sheet. You will observe that three tons of water per ton of ore is required in the flotation operation and that three tons more is added in the subsequent table-treatment. This, of course, includes the hydraulic classification, and I presume that something more than one-half of the last three tons is added in the classifiers themselves; and since the water is clarified and returned, the addition of unnecessary water would entail expense for clarification and pumping.

In my work in the concentration of ores I have not been able to become enthusiastic over hydraulic classifiers, and since flotation has come to the rescue of the slimed sulphide I find myself less enthusiastic than ever over their use. When I was a lad in the Black Hills I used to watch a mountain spring in which polished micaceous particles glistening in the sunlight would be caught in the current rising from an orifice in the bottom of the sand-funnel and be flirled to the surface, sail across the crater and fall upon the conical sides, to be methodically returned over the same route again. It was interesting to watch the disturbance caused by dropping a handful of foreign sand and silt into the funnel and have it 'classified' and washed clean, a new form of crater finally being established with the changes of average sizes retained. My first contact with hydraulic sizing in concentration was studied from that foundation. The spring took its time to do a good job! It worked the charge over repeatedly! All the silt went out quickly and the fine gradually went overboard with a rapidly decreasing ratio, until the crater would settle down again to its regular work of turning the mobile contents over and over in a new condition of equilibrium. But I soon learned that the beauty was all taken out of the process in its commercial application.

The process witnessed in the action of the spring was balanced, precise, and definite, and quite at variance with what we witness in watching through glass the operations going on in a teeter-chamber of the metallurgical hydraulic classifier, which seems to me to be of little value except in its office of washing out the slime that used to be the main source of the loss in treating unclassified material upon concentrating tables.

Following the thorough 'combing out' of the slimed sulphide as effected by the splendid flotation treatment that the pulp has previously received, I question the value of the subsequent classification by hydraulic means. I note that the flotation tailing is split into slime and sand at the drag-belts, that there is very little slime left

in the sand portion, and that what little there is (on account of the previous frothing) is completely devoid of anything the tables can save, as indicated by the fact that the main slime overflow of the drag-belt separators is discharged to tailing without further treatment. It seems to me that it ought to be possible to eliminate the classifiers, and I would like to ask Dr. Gahl if there has been any trial to determine what happens when the previously frothed sand-feed is put upon the tables for final treatment without hydraulic-sizing separation.

R. S. HANDY: I would like to ask if anyone has determined the relative economic efficiency of flotation as compared with gravity treatment on granular material.

E. P. MATHEWSON: It is the practice in Montana to take everything that is possible by means of tables or other water concentration machine; and at the Anaconda plant we take out a concentrate of 1½-inch, and keep on taking out finer and finer material by water concentration until we get to the tables. What is left from the tables and not saved is then ground up and put through the flotation. We find by our experiments that it is better to keep the slime separated from the feed, and we give them a little special treatment as regards sand.

DAVID COLE: I consider it unnecessary to first remove the slime, for the reason that after the slime has been subjected to flotation treatment there is nothing in it that a table treatment can save, no sulphides in a sufficiently fine state of division to be transported by the slime, because the previous frothing operation has removed it all, and when the slime is 'denatured' in this manner it is no longer harmful upon the table, and does not interfere with the working of the sand upon the table. The table will do exactly the same work upon the sand that it would do if the slime were not going across and off, in the rear of the sand, with the excess water. If no previous division or washing-out of slime is practised we have gained to the extent of the trouble and cost that would be entailed in making the division. That is the way I view the matter.

L. D. RICKETTS: I think it has been brought out that the ratio of concentration has something to do with the process of ore treatment. In other words, at Anaconda, where they have a low percentage of gravity concentration, flotation is applied only to the final cleaning up process. At Inspiration, flotation is the primary process, and gravity concentration is put in as a safety to prevent loss of coarse material, the reason being that in one case you have a low ratio of concentration and in the other a high ratio of concentration. When you come to ores with a moderate ratio of concentration, I think the balance would be in favor of getting as much gravity concentration as possible. So, I would say, in a great many of our plants with a great many of our ores, even where the ratio of concentration is only ten or twelve to one, it is profitable to have gravity concentration first, followed by flotation.

DAVID COLE: I have noted Mr. Mathewson's remarks concerning the Anaconda practice. Apparently he is under the impression that they really are desliming the

feed before treatment on tables. The Anaconda flow-sheet shows such a separation and the Anaconda type of conical deslimer is installed with that end in view, but like Mr. Mills's admission as to Inspiration's poor classification practice, Anaconda doesn't do good classification. The feed to the tables is not deslimed as it was intended it should be, the reason being that there are not enough of the Anaconda classifiers to do the work put upon them, and since the only office of these classifiers is to prepare feed for the Butchart riffle treatment, and since these tables have no office but to impoverish the ore treated by them, the complete separation of the slime from the feed is of little consequence, for all reject from the tables is taken at once to the re-grinding mills where the cleaning-up work is most thoroughly accomplished by the flotation process. If the tables were making a reject to tailing, the Anaconda classifiers would have to do their full duty in desliming the feed to them, because the slime going across the Butchart tables would result in serious losses, but since it is immaterial whether the primarily made slime reaches flotation treatment over the top of the classifiers or through the spigot, the classifier's inefficiency and the results as to the reject from the tables are tolerable and there does not seem to be any reason to change. Obviously, it does not matter at Anaconda where the copper is taken out so long as a minimum amount of it is allowed to get away with the final tailing, and it is also obvious that with Anaconda's present practice, wherein the ore is reduced by their splendid treatment scheme from a 60-lb. copper content to less than a 3-lb. copper tailing on a ratio of practically three into one, the chance for improvement in practice through modification or more perfect slime classification is extremely remote.

E. P. MATTHEWSON: I would like to make a correction in one statement I made that there has been no change made in our oil mixture at Anaconda. This change has been made: We found that the amount of wood creosote in treating the sand tailing was extremely small, and we tried some experiments on a large scale, dropping it out and using simply the sludge acid and sulphuric acid. We found that this gave practically as good results as wood-creosote. We use wood-creosote in treating slime. We find it necessary in that operation.

DAVID COLE: What is sludge acid?

MR. MATTHEWSON: Sludge acid is refuse from the refining of oil. It contains sulphuric acid and some greasy material from petroleum.

DAVID COLE: I believe that you are making sulphuric acid very cheaply at Anaconda. Since sludge acid consists of coal oil and sulphuric acid, I have wondered if you could not compound it at Anaconda more cheaply than you can buy it.

E. P. MATTHEWSON: We have made sludge acid at Anaconda, but it is more expensive than we can buy it outside. We got good results with the acid we manufactured.

NOELMA CARMICHAEL: One point which has not been touched on in this discussion today. In going through

the Old Dominion concentrator before luncheon, I noticed that they were using what appeared to be caustic soda. I think if there is anyone here who can give us any explanation in regard to the use of the caustic soda, it would be interesting.

W. B. KRAMER: We find, as Dr. Gahl finds, that the moment we use acid in flotation, our flotation suffers considerably. In fact, it almost ceases altogether. It is improved by the use of caustic soda. Caustic soda is expensive, and we are using about one pound to a ton. Soda has the effect of flattening the froth considerably, allowing us to cut down the water in the launders to less than half, which allows us to handle the concentrate in the Dorr thickener very well. Without the use of caustic soda, we may lose four or five tons of concentrate per day. It goes out and is recovered later in the secondary tanks.

C. W. MERRILL: I understand that the purpose of using caustic soda is threefold; to cut down the water, increase the extraction, and clean the concentrate.

DAVID COLE: Mr. Chairman, when we were at Chino a few days ago, we saw flotation-machines treating vanner-concentrate by aid of alkali and resin as the flotation agent. Mr. Ralston looked at this, and I would like to have him tell us what we saw.

O. C. RALSTON: That was a solution of sodium resin-ate. The resin has a good effect on the froth, making it particularly stable. They were working under conditions where the froth wanted to die, and the addition of the resin was the proper thing to bring up its strength and allow it to rise until it passed over the discharge-board. I think there was no significance in the alkali. In that case the alkali was not added for a particular purpose, but simply as a solvent for the resin.

THE CHAIRMAN: I understand that Mr. Ralston wishes to get some questions answered by the members of the Institute, and I will ask him to kindly present those questions.

O. C. RALSTON: The first one is this: What is the effect of dilution of pulp with water on the flotation of the minerals contained? The reason for asking that question is obvious. I think Dr. Gahl might help us.

REDOUF GAHL: I would say offhand that the effect of dilution is to make a cleaner concentrate, and make it more difficult to produce concentrate, because I think you would find that it would take more to produce the same amount of concentrate from a dilute part than from a stronger part.

O. C. RALSTON: Might I supplement by asking you what determines the amount of oil necessary for flotation. Is it the amount of water you are using, or is it the amount of mineral in the ore? If you had an ore consisting of 50% mineral, could you use more oil then if it contained 5%? What amount of oil must be used in flotation?

REDOUF GAHL: What is flotation? I don't feel like answering Mr. Ralston.

O. C. RALSTON: The Superior ore, containing 30% of oil, as compared with the Inspiration ore with

5 or 10% of mineral, uses probably less oil, if anything. So, the proposition would be that the amount of mineral in the ore is not determinative of the amount of oil necessary. It must be the amount of water that determines the amount of oil.

DAVID COLE: I think the kind of oil has a lot to do with the amount used.

O. C. RALSTON: That is a question not of theory but of experience. For instance, the pine-oils are being used in the Coeur d'Alene district at less than $\frac{1}{2}$ pound to the ton, while at Anaconda they use several pounds of oil per ton. At Anaconda they use a considerably less expensive oil.

DAVID COLE: Speaking of the small amounts of oil, we carried out some experiments the other day at El Paso, and on a density of 7:1, approximately, on an ore that contained 6% lead, 9% zinc, and 1.3% copper, with the use of $\frac{2}{10}$ pound of cresylic acid per ton, we were able to take out a large percentage of the lead. Then, by the addition of $\frac{3}{10}$ pound of No. 350 pine-oil per ton, we were able to take out the remaining zinc. The products assayed as follows:

	Weight	Gold	Silver	Lead	Cop- per	Iron	Zinc
	%	oz.	oz.	%	%	%	%
Lead concentrate	12.86	0.11	12.85	35.7	7.32	7.7	13.0
Zinc concentrate	25.08	0.025	2.67	4.4	1.30	3.9	23.6
Tailing	59.68	0.005	0.45	0.3	tr	3.0	1.9

This was done in a single operation without the use of a 'cleaner' on the concentrate. There was very little oil used—a total of $\frac{1}{2}$ pound per ton of ore. If we had used a larger amount of oil, we would not have been able to get the separation. We put in just enough cresylic acid primarily to get that result.

THE CHAIRMAN: I think Mr. Gottsberger might contribute something. The fact is that the Miami Company and the Inspiration Company are treating similar ores, except we, at the Chino, have not as much copper as they have. We use quite a little more oil in flotation than Mr. Gottsberger does; and I think, perhaps, they have got more water in the pulp. Is that about the condition, Mr. Gottsberger?

B. B. GOTTSBERGER: Our oil-mixture is much thinner because we are using less coal-tar. I think we have found that with a thick mixture composed very largely of coal-tar it is really necessary to add the oil in the grinding-mill. We do find, however, that it is not essential to add these oils in the grinding-mill in order to get good flotation work. At present the mixture is obtained in a bucket-elevator.

THE CHAIRMAN: Can you give us another question, Mr. Ralston?

O. C. RALSTON: Are ores that contain much fine material harder to treat successfully than granular ores? As far as I know, they usually are.

RUDOLF GAILL: That is my impression also.

O. C. RALSTON: There is another question in my mind. Is it possible to treat colloidal material? Would it be possible to deflocculate and separate the granular material?

F. S. SCHMERKA: Has it ever been noticed by the flotation experts present whether it makes a difference as to what density the pulp is when the oil is added in the grinder or mixing machine—whether a pound of oil goes farther at a high density?

Concentration at Miami

MILL STATISTICS, JANUARY TO JUNE, 1916

Dry tons milled	859,485
Tons per day	4,722
	%
Copper in feed, total	2.09
" " " oxidized	0.32
" " " sulphide	1.77
" " concentrate	41.74
Insolubles in concentrate	22.10
Copper in tailing, total	0.56
" " " oxidized	0.30
" " " sulphide	0.26
" recovered	74.06
Material in tailing, -48 mesh	12.53
Power, kw.-hr. per ton milled	12.97
Total men per day	208.76
Tons per man per day	22.62
Fresh water per ton of ore, gal.	321

MILL POWER-CONSUMPTION, JUNE 1916

	Kw.-hr. per ton
Crushing and grinding	7.86
Concentration	1.84
Reclaimed water	1.39
Miscellaneous	0.36
Total	11.36

WATER USED, JUNE 1916

	Gal. per min.	Gal. per ton
Total flow in mill	5471	1428
Fresh water	1273	332
Reclaimed water	4198	1096
Water reclaimed	76.8%	
Ratio, solid to water, total	1:5.95	

FLOTATION MILL

	%
Copper in the feed	1.95 (oxidized 0.5%)
Average copper in the tailing	0.60
Average oxidized copper in the tailing	0.45
Aerating and elevating, kw.-hr. per ton	2.95

Mixing is done by launders and elevator.

The oil is not mixed in the grinding-mills.

Fifty-hp. motors on blowers, 45 hp. used; 8 Callow roughers and 2 Callow cleaners per section.

Capacity, 75 tons per rougher cell.

EXPERIMENTAL PLANT

6 ft. by 22 in. Hardinge mill.

2-in. steel balls with 20 each of 4-in. balls.

One 6-ft. Dorr classifier, returning oversize.

Crushing from screen analyses to 1% on 48-mesh at rate of 115 tons per 24 hours.

Power used, including coarse crushing, 8.56 kw.-hr.

Density of overflow from classifier, 1:2.

Circulating load 500 tons sand returned, making 600 tons total load.

85% of concentrate made in plant will pass 200-mesh.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Acid is not used in flotation of Mount Morgan gold-copper ore.

SINCE GOLD-DREDGING operations commenced in California in 1898 until the end of 1915, the total output of gold from that source has been \$79,104,231.

OF THE PLACER GOLD produced in California in 1915, the dredges produced 90.5%, the hydraulic mines 5.0%, the drift mines 3.1%, and the surface or sluicing mines 1.4%.

TIMBER lasts longer and requires less replacement in a down-cast than in an up-cast shaft. In the latter the hot gaseous air from the mine tends to accelerate the decay of the timbers.

CADMIUM is not desired in zinc used in alloys as it makes them hard and brittle. For galvanizing wire spelter must be pure or the coating cracks and peels off under sharp bending in making splices.

OILS used in flotation at the Suan mill, Korea, consist of eucalyptus, 0.23 lb. per ton; pine-tar, 0.014 lb.; coal-tar, 0.115 lb.; No. 2 red oil, 0.173 lb.; and kerosene, 0.025 lb. Lime consumption was 2.8 lb. per ton.

EXCHANGE between New York and London is quoted at about \$4.75, that being the value of the English bank-note. But the 'sovereign,' which is the standard British gold coin of the value of £1, remains at \$4.8665, the price fixed by the United States government as measured in dollars.

COST OF POWER is usually given in cents per ton. This affords no basis of comparison. It should be stated in horsepower-years or kilowatt-hours. The actual cost of power as sold to the consumer is also a useful bit of supplementary information, when making any comparison of cost at mines or mills in widely separated localities.

MOUNT MORGAN ore consists of a mixture of iron pyrite, copper pyrite, and gold in a quartzose gangue. The smelting ore contains up to 50% silica, the concentrating ore 73%. The latter approximates 6% copper pyrite, 16% iron pyrite, and 78% quartz calcite. The gold is free but in a very fine state of subdivision.

Oil, used in flotation, especially in the treatment of copper ores, should be tested against a standard oil under standard conditions, and they should be purchased on results of testing and of fractional distillation, according to W. Shellshar in the June Bulletin of the Australasian I. M. E. Turpentine, which is not able to be distinguished from the first distillate of eucalyptus,

is too often used in large quantity as a diluent of eucalyptus.

THE THREE MOST IMPORTANT properties in rock used for constructing roads are hardness, or the resistance which the rock offers to the displacement of its surface particles by abrasion; toughness, or the resistance which it offers to fracture under impact; and binding power, or the ability which the dust from the rock possesses, or develops by contact with water, of binding the large rock fragments together.

DIAMONDS are valuable not only for personal adornment but find many varied uses in the arts and manufactures. Some of the more common uses are in glass-cutting, drilling and sawing blocks of hard stone, truving emery wheels, drilling in hard steel, and drawing wire for electric lamps. They are also employed in mining operations the principal of which is in deep borings. For this latter purpose amorphous diamonds, known as Brazilian carbons, are the most suitable.

CONCENTRATE produced at the Suan mine, Korea, in July, from 4350 tons of ore assaying \$9.85 gold and 0.91% copper, was as follows:

Class	Tons	Gold per ton	Copper %	Bismuth %	Gross value per ton
Regular	35.58	\$91.38	20.28	2.25	\$194
Canvas	1.33	140.65	9.44	2.86	212
Black	15.94	196.71	22.12	2.79	312
Flotation	83.93	28.07	28.08	2.06	156
Total	136.78	\$65.28	25.17	2.20	\$184

BLASTING BOULDERS is successfully done by block-holing, snake-holing, and mud-capping. In the first method a 1½-in. hole is drilled half through the rock, charged and exploded. In snake-holing a hole is punched down with a bar directly under but along side of the boulder. The hole must be deep enough to allow of the charge being placed under the heaviest part of the rock. Mud-capping is simple. Dynamite is laid on top of the rock, well covered with plastic mud only, 5 or 6 in. thick, and exploded. This system is not efficient if a boulder extends into the ground.

SONSTADT SOLUTION is prepared by taking a saturated solution of potassium iodide in water, and adding mercuric iodide until the required specific gravity of solution is obtained. At Mount Morgan this is used to determine whether gold occurs in quartz or pyrite. A minus 80 and plus 120-mesh sand was added to the Sonstadt solution and stirred well. To prevent its solidifying the solution was kept warm. The quartz floated on top of the solution, was skimmed off, filtered, and dried. The original sand assayed \$5.13 gold and 0.74% copper, the quartz product \$3.91 and 0.05% and the mineral product \$9.79 and 1.85%. This proved that a certain amount of the gold is associated with the quartz.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

FURTHER DRAINAGE NOTES.—PROBABLE LABOR TROUBLE.

Drainage of the greater part of the productive area of the Leadville district is the one great factor holding promise of increased activity in the future. Within the year the United States Smelting, Refining & Exploration Co. has erected a costly modern plant and buildings at the Harvard and drained the Fryer Hill basin to a depth of 700 ft.; ex-governor Jesse F. McDonald has organized the Down Town Mines Co., installed expensive pumping machinery at the Penrose, and unwatered the Down Town basin to a depth of 900 ft.; the Empire Zinc Co. and the Western Mining Co. have installed new pumping equipment at the Wolfstone and Greenback properties at considerable cost, and are now draining the big Pyrenees basin to a depth of 1350 ft.; and George O. Argall, manager of the Iron Silver Mining Co., is now re-timbering the Mikado shaft on Iron hill and installing modern pumping and hoisting machinery, preparatory to assisting in the draining of the Pyrenees basin and surrounding territory; while W. E. Bowden is re-fitting the La Plata shaft in California gulch for the purpose of draining the Rock Hill basin to considerable depth.

It is conservatively estimated that the combined cost of these pumping projects will total \$1,500,000. Without these enterprises Leadville would hold little promise of unusual activity in the immediate future. The greater part of the territory has been fairly thoroughly developed above water-level throughout that part that has for years been known as the Leadville district, and any developments of importance would necessarily have to occur in new ground. However, with these huge draining projects in operation, the possibilities of the future are unlimited. On Fryer hill, where all of the past exploration has been confined to the first contact, there is an expansive field for work at greater depth. The U. S. S. R. & E. Co., under the name of the Leadville Unit, as the Harvard enterprise is known, is now ready to begin sinking this shaft an additional 300 ft. into the second contract. In the early days Fryer hill and its very rich orebodies found at the surface were famous, but contrary to expectation later developments have been confined to the upper formations instead of going deeper. The Harvard will cut the parting quartzite within the 300 ft. of proposed sinking, and it is thought that the formations underlying will be found fully as rich as those that were mined above. This enterprise is considered to be the one holding unusual opportunities for great success.

The Down Town Mines Co. has undertaken and completed the heaviest pumping project in the district through the Penrose shaft. The entire basin is now drained to the bottom of the Penrose shaft, 900 ft., and development of the territory has been undertaken through the Penrose and Hibschie shafts. Past operations in this extensive territory uncovered immense bodies of iron and manganese ores, with occasional rich shoots of silver and lead ores. No development has been done throughout the Down Town section since carbonate of zinc was found in the Penrose dump, showing conclusively that this ore exists in the property. Zinc is undoubtedly the incentive for the unwatering of the Down Town basin, and the high spelter market tends to make the enterprise more promising. It is stated that the largest zinc lode in the district will be found in the Penrose, extending from the Bon Air to the south. Should this be found correct, and the market continues strong,

the Down Town company will be second to none in importance to the future of the district.

The parting quartzite has yet to be pierced in the Down Town section as in Fryer hill. Numerous faults have made several hundred feet difference in the depth of quartzite, it being much deeper in the Down Town area. Whether or not the work in the Penrose will be continued to great depth remains to be seen, but there apparently is a vast territory in this ground waiting to be opened. From the Penrose, north-west through the city and into the flats, little work has been done. A drill-hole was put down near the city limits several years ago, but was abandoned owing to trouble which arose

LEADVILLE DISTRICT, SHOWING POSITIONS OF PUMPING SCHEMES.

over titles to the ground, leaving no information as to what was discovered.

The undertaking of the Empire Zinc Co. and Western Mining companies for the draining of the Pyrenees basin through the Wolfstone and Greenback properties is an important one, because the area affected has long been one of the heaviest productive centres of the district. Several properties in this territory have been successfully developed at a depth of 1200 ft. The recent purchase of the holdings of the Small Hopes-Boreel Mining Co., adjoining the Wolfstone and Greenback, by the Empire Zinc, is one of the chief reasons for draining this area. The largest and most valuable body of lead-zinc ore that has yet been opened here has been uncovered in the Robert Emmet, one of the mines in the group. This ore-shoot persists below water-level, and is to be extensively developed following the unwatering. The Wolfstone and Greenback also hold possibilities for deeper development. It is reported that before the present drainage scheme is completed, the Wolfstone shaft will be sunk several hundred feet. Large deposits of copper ore at great depth are looked upon as a certainty in this ground. Most of the ore that has been mined has carried a high copper-content.

The Mikado scheme, under the management of George Argall, is probably the largest here. The preparations that have been made at the Mikado shaft mark it as one requiring the expenditure of much capital, justifying large returns. The ground to be developed has produced heavily in the past, and in on the trend of the large ore-shoots developed in the Green-back, R. A. M., and adjoining properties. The success of the undertaking is already considered assured, although now only in the first stage of preparation.

The La Plata project is far from the other drainage companies, but in a locality that promises unusual results. Carbonate of zinc is again the incentive here.

The result of the entrance of these live draining enterprises into the district is a revived Leadville. They have already given employment to several hundred men, and it is conservatively estimated that another thousand will be put to work following the completion of pumping. This means a bigger production, a bigger pay-roll, and better business and living conditions. The city has undergone a remarkable change during the summer. Carpenters and painters have had a busy season repairing all the old vacant houses that have come into demand. Real-estate men state that there is not an empty house in the city that is habitable, while a year ago there were scores to be had at low rents. Leadville is now looking forward to the best years in its remarkable history.

The labor question is again assuming a threatening aspect, due to the activity of the miners' union. Letters have been sent to the operators asking that they recognize the union, and a campaign has been started to organize the miners. A new scale of wages is to be demanded, it is reported, calling for \$3.75 to \$4.25 for 8 hours' work. It is generally considered that this is an inopportune time for demanding higher wages, because several large and important companies have just entered the district and are still engaged in draining and developing their holdings at their own expense, no ore being produced at this time. Furthermore, these companies have spent \$1,500,000. A demand for higher wages would, it is believed, cause these enterprises to shut-down. The labor question in Leadville always has been and always will be a problem. In many mining districts where one metal is mined, as in the copper centres of Arizona and Montana, it is possible to institute a schedule of wages subject to the market price of the metal produced, an easy and most satisfactory manner of handling the question. In Leadville, however, its production of many metals widely differing in value make it impossible to institute a schedule, and makes it very difficult for the operators to arrive at a wage-schedule satisfactory to all. The average value per ton of the ore mined in the Leadville district is \$27.50, but the production from several of the mines nets less than 25c. per ton, while from others it will net \$100. A raise in wages as is now to be asked by the union would shut-down the low-grade properties and put several hundred men out of work. Efforts are being made to adjust the situation before definite steps are taken by the union.

In the issue of November 4 another letter from Leadville will deal with the labor situation in detail.

JOPLIN, MISSOURI

TREATMENT OF TAILING FROM SHORT CREEK

An approach to Western methods is a form of dredging just started by C. J. Rhodes of Joplin, on the sand and gravel bars of Short creek, west of Galena, Kansas. The lower reaches of this stream, just before it enters Spring river, contain long and wide deposits of sand and gravel that are the debris resulting from 25 years' mining operations extending from Central City, Missouri, through Galena, and North Empire, Kansas. A sampling of these accumulations developed the fact that they contained zinc amounting to from 2 to 20%. Mr. Rhodes conceived the idea of building a barge and using a sand-pump driven by Diesel engines as a method of handling

the debris and getting it to a mill upon the bank of the stream. A plant to treat the material is now being constructed with a capacity of 100 tons per day. It will be on the order of a sludge or tailing-mill, similar to the regular type of construction with the exception of a crushing plant. The table-room will start with eight sludge or sand-tables, and part of the larger sizes will be run over sand-jigs. As this method is an innovation in this region it is being watched with considerable interest, as there are other streams in the district that may give equally good results if this operation proves successful.

CHANGSHA, CHINA

RECEPTION GIVEN TO AMERICAN MINING ENGINEERS.

A dinner was given by the Hunan Mining Association in honor of Messrs. F. Searls, G. O. Scarfe, mining experts, the American Consul Mr. Johnson, Mr. McRae of Anderen, Meyer & Co., and several other American residents in Hunan. The dinner party was held in Mr. Wong-Cheng-Tsai's residence, which was beautifully decorated for the occasion.

The first toast, "Chinese-American Friendship" was proposed by Mr. Cheng-Ping-Hwan, director of the Hunan Mining Board, and was well responded by Mr. Searls, who gave some very valuable suggestions regarding the necessary steps which should be taken in order to develop the mineral resources of Hunan, the richest province in China. Mr. Searls remarked that America was only discovered in 1492, and in less than 500 years she had become the greatest mining country and the wealthiest nation in the world. It would not take China very long to develop her industries in the same way if she determined to do so. In conclusion, Mr. Searls wished that the two countries could have more intercourse and do more to develop their trade. He also thanked the hosts for their kind hospitality and wished them every success in their mining enterprise. The speech was interpreted by Mr. C. C. Lu, chief of Technical Department of the Hunan Mining Board. Then Mr. K. C. Li, mining engineer of the Board, proposed "Our Guests," thanking them for their valuable assistance and all kinds of beneficial works done for Hunan and for China at large. Mr. Johnson, the American Consul, responded in a humorous way. He wished that China would have more of her industrial magnates on the political stage with a definite program of industrial development, which was the only way for China to gain prosperity.

JUNEAU, ALASKA

GENERAL CONDITIONS.—KETCHIKAN, JUNEAU, WHITE PASS, COPPER RIVER, AND LA TOTCHE DISTRICTS.—RAILROAD AND COAL.

Alaska, in common with other mining regions, is enjoying the prosperity caused by the prevailing high prices of metals. The year 1916 will record a production greater than in any previous period. This is due largely to the wonderful copper production of the Kennecott mines, also to the increased activity of the low-grade gold deposits near Juneau.

Much development has been done in the immediate vicinity of Ketchikan. This district can be credited with a considerable production of copper, in fact, at present 12 mines are shipping; both to the Granby smelter at Anxox, British Columbia, and to the Tacoma smelter at Tacoma, Washington. The combined output amounts to approximately 10,000 tons per month, the principal shippers being the Granby Consolidated company, operating the Mamie, 30 miles north-west of Ketchikan; the Mt. Andrews property, controlled by New York interests; the Rush & Brown property; the Alaska Industrial Co., whose property is on Prince of Wales island; and the Goodlow Bay mine, owned and operated by J. E. Chilberg, a Seattle banker. The principal ore of this district is chalcopryite, associated with magnetite. Some of the companies are shipping ore that is mined from contact metamorphic deposits,

which carry bornite, epidote, and garnet. The average ore shipped varies in copper content from 4 to 20%, and contains small amounts of gold and silver. The freight-charge to the smelters is reasonable, while the smelter-charge amounts to about \$5 per ton. This district has been examined by several engineers representing the larger exploration companies, but so far no properties have changed hands.

Near Juneau the principal operating companies are the Alaska Treadwell group, the Alaska Gold Mines, the Alaska Juneau, and the Ebner. The Alaska Gold or Gastineau mine is milling 130,000 tons per month averaging \$1.30 per ton, the extraction by concentration being 80%. This property, like others, has been affected by the increased cost of mining-supplies, and the desertion of efficient miners to the more prosperous copper districts. The efficiency of the machine-drillers has decreased 25% since the War commenced; consequently the cost of breaking ore per ton has increased 3c., from 14 to 17c. per ton. At the present time most of the ore sent to the mill comes from the east side of the mine, where the

tons daily. As the mine-development to the east progresses the mill will be gradually speeded-up. Owing to the contour of the ground and the lay of the orebody on the west end, the ore must be taken from certain places first, in order that the mine's producing capacity be not impaired. This work is now progressing rapidly and large bodies of ore of a higher value are being opened for stoping purposes, and within a short time the mill will be operating at capacity, as the company will be able to take the ore from the east end and mix it with the west-end ore, bringing the average to the correct grade."

Work on the Alaska Juneau mill is proceeding. At present almost all the concrete and structural-steel work has been finished, and the mine is being put in order. This company is getting the benefit of the pioneer work done by the Alaska Gold and should be in full operation by the early part of the coming year.

Much activity in mining is to be noted in the territory served by the White Pass & Yukon railroad. At Caribou the Big Thing mine is being re-opened, and along Taku Arm

CHICHAGOF, ALASKA.

gold-content is lower than at the western end, but levels are being driven and raises put through preparatory to working this part of the property. When intermediate levels are driven in the gabbro along the foot-wall, preparatory to stoping, the slate breaks away (sloughs-off) bringing part of the hanging with it, so that the gold-content is lowered by the waste. The management is trying to stop this by working in narrower stopes on the east side, where the ore is richer, mixing the output with the lower-grade supply from the west end of the mine. The company at present is employing 800 men and eventually, when the mine is thoroughly developed, will be able, by merely adding another pair of 72-in. rolls, to supply 12,000 tons per day to the mills. The operating cost is 65c. per ton. This property possesses enormous reserves of low-grade ore; these are measured by an adit 13,000 ft. long and a shaft 1700 ft. to the surface, and a width of ore 85 to 200 ft. A statement recently issued by B. L. Thane applies to the present status of this property and is as follows:

"Since the beginning of the operation of the big mill, the average cost of mining and milling the ore has been under 75c. per ton, which was the original estimate made by the engineers. Eminent men of the mining profession freely predicted that the cost could not be reduced to 75c. as estimated. For the past few months the cost has been 65c. and under. The mill is at present being operated at a 6000-ton daily capacity, which was the original daily estimate, but its actual capacity is more than double that amount or between 12,000 and 15,000

tons daily. The Venus and Engineer mines are being operated. These properties are shipping to the Granby smelter. The Engineer mine was recently examined by representatives of the Tonopah Belmont Development Co. At White Horse, the northern terminus of the White Pass & Yukon railroad, the Pueblo and Grafter mines are shipping 4000 to 5000 tons of ore per month. The Pueblo ore consists of hematite containing 3 to 4% copper, used principally as a flux at the Granby smelter; the Grafter ore is of a silicious character with chalcopryite. In the Atlin district the placers commenced operations in the early part of May, but were hampered by a lack of water later in the season. The operations on Spruce, Discovery, and McKee creeks in this district will produce \$400,000 this season. The gold is valued at \$16.50 per ounce; 500 men are employed during the season.

Along the Copper River & North-Western railroad, 196 miles north of Cordova, is the famous Kennecott mine. This mine is producing about 10,500,000 lb. of copper per month at a cost of 5c. per pound. The ore is found along the contact of limestone and greenstone, in large lenses lying in the limestone about 30 ft. from the contact. The main workings are known as the Bonanza, Jumbo, and Erie, the deepest shaft being the Jumbo, with a depth of 750 ft. Between the 600 and 450-ft. levels on the Jumbo there is a lens of ore 450 ft. long and 150 ft. high, averaging 50 ft. in width. This is first-class ore, and the company is mining it as fast as possible in order to make the most of the high price of copper. The mine employs

350 men, and shipped 8500 tons of ore during the month of August, averaging above 60% copper. There is 20,000 tons of ore, sacked and concentrated, at Cordova, the Pacific Coast terminus of the railroad, ready to be shipped to the smelter at Tacoma.

The Heatson mine, belonging to this same company, is operating a low-grade chalcocite deposit on La Touche island. The mill is being increased to treat 1000 tons per day by the flotation process, the concentrate being sent to Tacoma. The Elkumar mine is shipping 4000 tons per month to the Tacoma smelter. Roy Middlecamp is manager and the mine employs a force of 200 or more. The ore is well oxidized and carries a high gold-content besides about 4% copper per ton. A contract has been let recently for diamond-drilling intended to intersect the vein below the 600-ft. level. The production of the copper mines lying between Cordova and La Touche has been seriously hampered by the lack of steamship-transportation facilities, but this condition will be improved by the recent addition of several new boats by the Pacific Alaska Navigation Company.

On the Government railroad the Alaska Engineering Commission is employing a total of 800 men on the Seward division, 2500 on the Anchorage division, and 500 out of Fairbanks. The old Alaska Northern line is being repaired, and new bridges are replacing the old bridges at Placer and Portage rivers. This railroad will be rehabilitated completely as far as Kern Creek, 71.6 miles north of Seward, by October 30. The work is in charge of R. J. Weir, formerly with the Southern Pacific. From Anchorage the road is completed as far as Matanuska Junction, and thence about 15 miles to Moose Creek, toward Chickaloon, in the centre of the Matanuska coal-fields. The spring of next year will see the completion of this branch road to Chickaloon. At present, under the system of leasing introduced by the Interior department, one coal lease is operated by Richard Doherty at Moose Creek. This property is supplying the railroad with 3000 tons of coal. The restrictive conditions imposed by these leases are such that experienced operators are not attracted. The Willow Creek district, 30 miles north of Knik, was extremely handicapped by the lateness of the spring. At present the Gold Bullion, Independence, Mabel, and Jap properties are being operated. The total production for this district is estimated at \$500,000, and the principal portion of it should be credited to the Gold Bullion. The small veins occur in granite, and the ore in small shoots at frequent intervals. Mining operations can be continued in this district for only six months of the year owing to the hard winters and lack of water for milling purposes. Several prospecting parties entered the Broad Pass district, but no discoveries of any consequence were reported.

SUTTER CREEK, CALIFORNIA

STRIKE SITUATION.—CENTRAL EUREKA LOSS.—OLD EUREKA.

About 200 men awaited the arrival of each train at Martell yesterday, the 21st, the striking miners having heard rumors that a number of miners were to arrive here to take the places of the strikers; but apparently the report was not well grounded, as the expected strike-breakers did not put in their appearance. Attempts have been made to stop merchants, bakers, and butchers from delivering supplies to the South Eureka property, where the company has employed a dozen or more men from the outside to work as guards. These men are camped on the company's ground. At the present time, the Kennedy company has 111 men on its payroll and the Argonaut 100. At the other mines, south of Plymouth, only sufficient men are at work to keep the mines open and make necessary repairs. J. B. Dale, organizer for the State Federation of Labor, has spent several days in the county, endeavoring to get the matters settled by arbitration, but the mine-owners insist that they have nothing to arbitrate, and

are ready and willing to resume operations on the old basis, when a sufficient number of the men express a willingness to return to work. The mine operators have appealed to the U. S. District Court to prevent interference with their operations by striking miners, and Judge E. S. Farrington issued an order today, restraining the strikers from committing violence pending a hearing of the application for an injunction. The companies claim that their property is valued at more than \$1,000,000, and unless their employees can pass freely to and from the mines irreparable damage will result from cave-ins and flooding. Over a month has elapsed since the strike began, and in that time 500 miners have left the county to seek work in other localities.

During September, or that portion of the month prior to the miners' strike, the Central Eureka company reports 1676 tons of ore crushed, yielding 204 oz. of bullion valued at \$3422; concentrate yielded \$2660 for the 22 days' run, and sundry collections brought the total receipts up to \$6138. With the exception of three days' milling after mine operations ceased on the 19th of last month, only pump-men and engineers have been working during the strike. The total expenditure for mining, pumping, and shaft repairs for the whole month was \$4976; milling, \$1043; development, \$1658; tailing dam, \$387; indemnity insurance and sundries, \$841, making a total cost of \$8905, or a net loss on the month's operations of \$2767.

The Old Eureka company is preparing to install a 9000-gal. tank or reservoir at the 500-ft. station, to be supplied by large pumps at 600 ft. and levels below. It is estimated that the lower pumps will have sufficient capacity to fill this reservoir in 18 minutes. A centrifugal pump at the surface will raise the water from the 500-ft. level. Twenty-five men are employed at present in the shaft, and 30 on surface construction and installation of the large hoist.

The new double-drum hoist for the Old Eureka mine arrived during the week and is now in course of installation, the foundations for same, as well as for the new steel head-frame, shortly to be erected, having been ready for over a week. The new hoist is a powerful one, capable of raising 15,600 lb., and being efficient for a depth of 2000 ft., nearly 1000 ft. below the present shaft-bottom. The water has been removed to a point just above the 800-ft. level, and the shaft-men have for some distance found evidence in the way of charred timbers of the fire that caused the closing down of the mine over 30 years ago. The work at the last operating of the mine did not extend below 800 ft., although the earlier working of the mine had yielded well when the shaft was open to 2100 ft. It is expected that the condition of the shaft below the 800-ft. station will be much worse than that passed through above, as that portion also is said to have been burned out a number of years prior to the last operations. Caves in the shaft will doubtless be encountered and more difficulty be met with in re-timbering, but by means of the adequate machinery now being installed the owners appear hopeful of getting the entire shaft unwatered and repaired early in the coming year. Three crews of shaft-men, as well as a large force of mechanics and carpenters, are working steadily in re-opening this old property, which has a record of yielding no less than \$10,000,000 during former operations, when mining and milling methods were crude and operating costs excessive. The superintendent, T. Walter Beam, has recently engaged George Pettigill as foreman.

The elevated track on which cars will carry the ore from the Argonaut shaft to the new mill in course of construction to the west of the present plant, is now being erected. The mill is 800 ft. from the ore-bin at the mine, and two tracks up this steep incline will be used, the descending car helping to balance the ascending one, one man on a shift being sufficient to handle the car system, including loading and dumping. Machinery is being installed in the mill, which will be equipped with 60 stamps, or 20 heavy new stamps in addition to the 40 used until recently in the old mill.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

FAIRBANKS. On September 17 the new Lane mill of 20-ton capacity started work on the Thomas gold-quartz mine at the head of Eva creek. This property has been thoroughly developed. On the road to it are several promising mines.

VALDEZ. After several weeks' shut-down for development of the mine the Granite mill resumed crushing recently. High-grade ore was opened on one level, and good grade on two others.

ARIZONA

(Special Correspondence.)—For the nine months ended June 30, 1916, 873 cars of ore was shipped from Chloride. There are now 40 properties here in active operation and several others soon to be started.

The oldest and most historic property at Chloride, the Silver Hill mine, is again being operated. H. M. Henning, the present owner, arrived here last week and at once started men cleaning-out the old 600-ft. adit. This cut the vein when work was stopped years ago, since then it has not been worked. Bad management was the direct cause of the failures in the past. It was on this property, a long time ago, that three miners were murdered by Indians while working in a shaft. The Indians stood at the collar of the shaft and stoned the helpless miners to death.

The Towne mine has been shut-down awaiting the arrival of the new head-frame, hoist, and compressor, which should be on the ground this week. A new shaft is to be sunk, as the old one is in an unworkable condition. This mine was recently unwatered and sampled, with the result that the owners are highly pleased and purpose to prosecute work vigorously.

The Desert Power & Water Co. expects to have its high-tension line into Chloride within three weeks. Many mines will install electric hoists.

It is said that the new shoot in the Keystone surpasses any heretofore made in this district. On the 300-ft. level 8 ft. of ore assays 226 oz. of silver and 1.4 oz. gold.

A new three-compartment shaft has been started between the Keystone and Silver Keystone properties, so that both may use the same shaft in drawing ore for the new mill that is being constructed.

On the Black Jack property a new adit has been started which will cut the ore at a depth of 450 ft. A contract has been let for the construction of a road from the mouth of Alum Wash to the property. The ore will then be hauled with trucks. Sixty burros are now employed in packing the initial shipment of 250 tons.

The Copper Age has begun excavating for a reservoir. This work is preliminary to the beginning of mill construction under the direction of G. W. Peer. The mill will be in operation by February 1.

Julius Kruschmitt, south-western representative of the Guggenheims, left on October 10 for El Paso, taking with him the samples from the Brunswick, Golden Hammer, and the Holmes properties at Hackberry.

The Tennessee Extension has men at work. It is a close neighbor of the Tennessee, Payroll, and Minnesota-Connor. A contract has been let for an extension of the present adit. Chloride, October 16.

(Special Correspondence.)—Shareholders from Kansas City

and Omaha will arrive at Gila Bend this week for an inspection of the Rowley Copper Mines Co.'s property. The work is being done under the supervision of C. T. Jobes, chief engineer. L. C. Harden of Phoenix is the foreman. A shipment of silver-lead ore made from the new No. 3 shaft to the El Paso smelter last week, returned lead and silver amounting to \$93.96 per ton. Work at the Rowley is being confined to driving along the high lead-silver vein and to deepening the vertical and the No. 3 shafts. Twenty-five men are employed.

Gila Bend, October 15.

JEROME. Within a few months the United Verde Copper Co. will commence mining low-grade surface ore around the old

MINES OF MOHAVE COUNTY, ARIZONA.

smelter at Jerome by means of steam-shovels, and sending it to the works at Clarkdale. Excavation is to proceed to the fire that has been burning for 14 years in the Hampton stope. The fire can then be attacked from above. When No. 5 shaft of the mine is concreted, and the large electric hoist installed, ore production will be augmented. The smelter is soon to reduce 2500 tons daily. A second reverberatory furnace is in commission, also three blast-furnaces.

N. Bertrand of Bisbee has a contract to diamond-drill the Verde Hercules ground to a depth of 1500 or 2000 ft. This mine was formerly the Harryhausen.

HAYDEN. It is reported that the Ray Consolidated Copper Co. is preparing plans for a 6000-ton plant to treat its tailing. The works will be on the banks of the Gila river, and will cost \$500,000.

MIAMI. An employees' grievance committee has been appointed at the Inspiration, with the sanction of the company, to discuss with the management any disputes that may require ventilation.

NEEDLES. Reports state that the Colorado river is running wild, making transportation between Oatman and Needles a difficulty. Several automobiles were caught between the river and water that leaves the main channel when the river is high. Cars are going by way of Topock. Floods at this season are unusual. When the water recedes several miles of road must be re-built.

(Special Correspondence).—On account of certain derogatory reports circulated a few weeks ago in a campaign to bear shares of the Big Jim mine, the management secretly put up a raise a height of 150 ft. from the 400-ft. level. At that point a cross-cut was driven from wall to wall, and both raise and cross-cut are in ore throughout, averaging \$20 and over per ton. There having been no opening in the ore above 400 ft. nor below 485 ft., the bears alleged only ore between the levels could be taken into account in estimating reserves.

The Gold Dust has opened its ore-shoot for a vertical depth of 476 ft. from the surface. As exposed, the ore averages from 1 to 2 oz. per ton in gold. Seven hundred feet north-west of the shaft, surface assays of that value were found several years ago; with that as an object the drift was driven recently. From thence the winze was sunk 76 ft. and is in 2-oz. ore at the bottom.

The Boundary cone has opened a second large shoot of milling ore 560 ft. east of the shaft on the 550-ft. level. One passed through on the same level, with low-grade ore between, is being driven 325 ft. east on the 750-ft. level, and in both faces assays run from \$10 to \$60 per ton. Converging in the Lexington-Arizona ground eastward and passing through the Paramount on the west, these two veins are of the highest significance to the district.

For two weeks the Pioneer has been cross-cutting from the north drift westerly on the 200-ft. level, at a point 200 ft. from the end-line of the Arizona-Tom Reed. Being under the one management the object is to develop both properties. In this area a vein at one point averages \$25 per ton.

The Nellie has made a rich surface discovery, 25 ft. from the boundary of the Black Range and 115 ft. from the spot where the latter made its recent strike. The manager, H. E. Woods, started a shaft and at 2 ft. he opened 5 ft. of ore assaying \$2.48, \$6.61, \$8.68, and \$19.61. Pannings average about \$15, which is a fine surface showing for Oatman.

Oatman, October 15.

OATMAN. The Los Angeles Mining Bureau states that the most important developments of the week ended October 14 relate to Big Jim and Tom Reed mines. The Tom Reed has developed ore in its Pasadena claim a little over a mile north-west of its main workings, and ore has been encountered at 400 ft. depth in its Bald Eagle claim, which extends the known length of the Aztec-Black Eagle vein more than 200 ft. It is estimated by Oatman mining men that the Aztec-Black Eagle vein promises to develop into a greater mine than the original workings of the Tom Reed in its Ben Harrison claim.

It is semi-officially announced by the Big Jim company that the raise from the extreme end of the east drift on the 400-ft. level has resulted in highly important developments. The raise was carried to a point 160 ft. above the 400-ft. level, and at this point broke into extensive lateral work done on the vein by the Tom Reed company, which had been doing exploratory work with reference to it. Grey Eagle claim, adjoining the Big Jim on the south. On this level, which corresponds to the 240-ft. point in the Big Jim shaft, a drift had been put in on the vein for 240 ft., and a raise in the vein for 50 ft. This work was done recently by the Tom Reed company, which, some time ago, did extensive searching in and adjacent to its Grey Eagle claim, adjoining the Big Jim on the

south. The Grey Eagle shaft was put down about 300 ft. vertically. At about 200 ft. a cross-cut was driven to the north, not only to the Grey Eagle-Big Jim side-lines, but into Big Jim ground some 40 to 50 ft., and into the Big Jim vein. At this point the upward extension of the Big Jim vein was inclining somewhat sharply to the south, or towards the Tom Reed ground. It certainly looked as though the Big Jim vein passed through the side-line and apexed on Tom Reed ground. Along the line between the two properties is a strong intrusive dike that at places outcrops boldly at the surface. The raise put up by the Tom Reed showed that when the Big Jim vein reached the vicinity of this strong dike, it folded and bent back toward the north, and at the point where the vein came closest to the Tom Reed ground, it is some 30 to 50 ft. within the Big Jim side-lines. From this point, going toward the surface, the angle of the vein is toward the north, thus indicating that its apex is some considerable distance within Big Jim ground. It is significant that the lower part of the Grey Eagle shaft below this level was filled with refuse matter from operations on that level. A considerable tonnage of Big Jim ore is on the Grey Eagle dump, and the Grey Eagle work and shaft now afford a second outlet and an air passage for the Big Jim workings. Had the Tom Reed not done this work, it would have been necessary for the Big Jim to make a second outlet at its own expense. The second outlet and driving operations on the vein done by the Tom Reed company for them saved the Big Jim company approximately \$25,000 to \$30,000. It is notable that the 240 ft. of driving on this vein by the Tom Reed company extends a known lateral length on this vein 240 ft. beyond the extreme western point at which development in the vein had been done by the Big Jim company. The Big Jim is now doing work in this drift, and superintendent Keating states that it shows a large body of ore which he anticipates will average in value as well as, or better than, the ore on the 400-ft. level. With this new development, the Big Jim ore-shoot has been opened on various levels from the extreme eastern point to the extreme western point, a distance of 700 ft., and shows an orebody of a known height of 245 ft., and which seems to average well above 25 ft. in width. It is stated that the last 45 ft. of new openings in the west drift on the 485-ft. level average in excess of \$40 per ton. These developments are highly significant and still further bear out the opinion of mining engineers who have expressed the belief that Big Jim is developing into a mine which, foot for foot, of development closely parallels the Tom Reed and United Eastern.

Important developments are expected during the next few days on the Iowa, Picture Rock, and Nellie properties. All of these companies are just breaking into their main vein systems, and indications are highly favorable. It now appears as though Oatman is due for important developments in a number of properties at approximately the same time.

CALIFORNIA

HISTOR. The Tungsten Mines Co. shipped concentrate worth \$20,000 last week. The mill is working full time.—Operations at the Standard tungsten mine are progressing steadily.

GRASS VALLEY. The North Star company has distributed No. 3 dividend for the current year, amounting to \$50,000. The total is \$1,937,000. Good progress is being made with plant alterations.

NATOMA. No. 7 dredge of the Natoma company has been righted and is again at work. Some time ago the boat capitalized to put it in commission cost \$150,000. Red-dredging tailing at Oroville is reported to be most satisfactory.

REDDING. A 250-hp. Diesel engine is expected any day at the Midas coal mine in Harrison Gulch. The mine is then to be unwatered to the 1200-ft. level, where a fire occurred in 1913. J. H. Sharpe is president of the Victor Mining & Power Co., the owner.

(Special Correspondence).—The Confidence mine, for many

years one of the most consistent producers of Tuolumne county, is to be re-opened by the Confidence Gold Mines Corporation, which filed articles of incorporation here this week. A decade has passed since the suspension of operations, previous to which the mine regularly employed 40 men. Its total yield is upwards of \$5,000,000. In addition to an 850-ft. incline shaft, from which drifts of varying lengths were driven, there is a winze from the bottom level that is 250 ft. deep. The capital of the new concern consists of 1000 preferred and 5000 common shares of the value of \$100 each. The officers and directors are W. A. Stratta and E. S. Bolen, of Richmond, Va., and Warren B. Hunting, of New York.

After several weeks of continuous pumping the Columbus mine, near Tuolumne, has been unwatered, and with as little delay as possible development will be resumed. The Columbus is one of the oldest properties on the east mining belt, and in its early period of activity yielded considerable gold. The company which now has the property is reputed to be strong financially. It is the general belief that extensive exploration work will follow.

A body of rich ore, 3 to 4 ft. wide, has been uncovered in the Gem mine, operated for the past four years by J. F. Wulzen. The strike was made in a winze sunk near the face of an adit driven many years ago, and is regarded as one of the most important made on the east belt for a long time. Much of the quartz is speckled with gold.

The Buckeye mine has passed into the hands of a New York company and will shortly be re-opened and operated. Half the wages that were due miners when the property closed some time ago were paid recently, and the remainder is promised within 60 days.

Rich ore has been uncovered in the Bacigalupi claim, northeast of Tuolumne. The operators, encouraged by the find, have announced their intention to develop the property to a much greater depth.

A few mines which suspended operations recently on account of a scarcity of water, have been able to resume work as a result of the copious rains of the past several days.

Sonora, October 12.

COLORADO

GEORGETOWN. Lessees at the Capital mine are to ship to the mill or smelter to try the gold ore from the rich shoot in No. 15 rise. A trial run at the mill resulted in the tailing containing 200 oz. per ton. All the other lessees are busy, getting encouraging returns.

Dumps at the Ocean Wave and Equator have been measured, and contain 360,000 tons of \$7 to \$10 ore. There are 42 men employed at the mine.

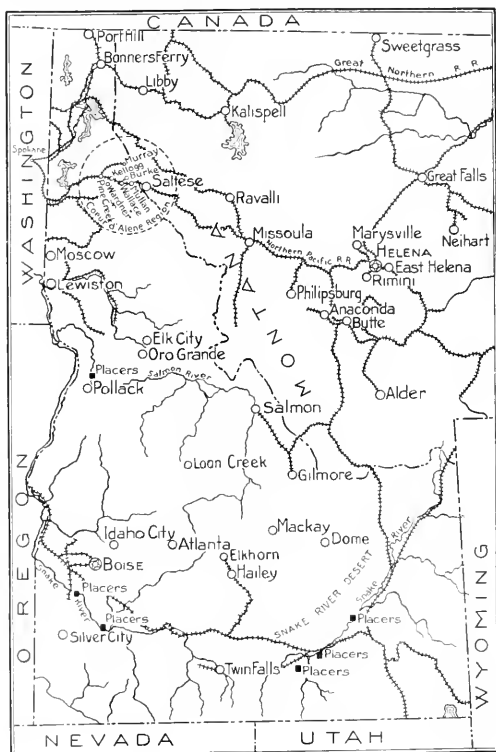

IDAHO

HAILEY. There is more activity in the Wood River district than for many years, the entrance into the field of extensive Eastern capital having given mining a much-needed impetus. The \$40,000 option on the Smoky Bullion group of gold-silver-lead claims, 35 miles west of Hailey, held by the United Mines Co. of Spokane, is to be exercised soon, according to E. A. Worswick of Lovelock, Nevada, owner of the properties.

NINE-MILE. The Interstate-Callahan company is mining up to 15,000 tons of ore monthly, yielding 6500 tons of zinc and lead concentrates. The Minerals Separation company is to install additional flotation apparatus to cost \$50,000. Impounded tailing is to be treated. This will make 800 tons more concentrate. There are 400 men employed, receiving \$85,000 per month. No plans have been prepared for the much-discussed mill at Enaville. The next quarterly dividend is expected to be at the rate of \$1.50 per share.

WALLACE. According to H. C. McAllister, there are perhaps 100 properties in the Coeur d'Alene region, of which the public hears little, that are in the same stage of development today as some of the great producers were 10 to 20 years ago. The

exposures in a large number encourage belief that not a few will ultimately take the place of large present producers.

MAP OF IDAHO.

MICHIGAN

HOCHEM. Copper production of the Culmet & Hecla and its subsidiaries during September was as follows, in pounds:

Mines	September	9 months
Ahmeeek	2,309,955	17,685,686
Allouez	896,184	7,649,473
Culmet & Hecla	6,257,447	57,191,355
Centennial	160,800	1,828,245
Isle Royale	1,010,723	9,226,225
La Salle	119,269	954,489
Osceola	1,700,522	14,935,700
Superior	220,582	2,354,530
Tamarack	512,666	4,949,184
White Pine	385,577	3,280,142

The Hancock company is gradually getting straightened financially. During October there will be over 24,000 tons of ore treated at two mills. The mine is opening well, and 400 men are employed.

At the White Pine Extension development consists of driving north and south at 200 ft., where the average copper-content is 30 lb. per ton.

Another exploration company is to start in Ontonagon county at the Waukulla property, in charge of H. Hillegass.

Allouez is producing at the rate of 12,000,000 lb. per year.

MISSOURI

JOPLIN. The zinc-ore market was stronger last week, the range of prices being from \$62.50 to \$70 per ton for 60% metal-

content. Lead ore was strong, and calamine steady. The Missouri-Kansas-Oklahoma region produced 6478 tons of blende, 720 tons of calamine, and 884 tons of lead, averaging \$61, \$39, and \$80 per ton, respectively. The total value was \$516,654, and for 41 weeks \$26,276,951.

The Norfolk Zinc Corporation, a new company headed by J. M. Short, is to erect a 100-ton mill costing \$40,000, north of the well-known A. W. C. mine. Thirty drill-holes averaged 3% blende at a depth of 175 feet.

MONTANA

BUTTE. For its issue of October 15 *The Butte Miner* publishes 112 pages, most of which are styled as the "Greater Montana Edition." Interesting reading covers mining, power, and other industries. Photographs show leading men of the past and present, mines, and plants. A panorama illustrates the eastern section, now attracting attention. The smaller properties of the district are discussed briefly. Buildings and homes are shown. Transportation systems are described. Historical incidents of the State, as far back as July 4, 1865, at Virginia City, are told. The Governor describes Montana as an "empire of opportunity." Lumber and farming is not omitted from this readable issue.

September at the Butte & Superior was a normal month, all shafts and machinery being in good order. The mill treated 50,150 tons of ore assaying 15.5% zinc. The 13,650 tons of concentrate contained 53.1% metal. The recovery was 93.46%.

The north vein in the North Butte promises to be of importance, as two cross-cuts have opened ore assaying 10% copper and 30 oz. silver per ton.

Additions to the Butte-Detroit mill are complete. A flotation plant similar to that at the Butte & Superior has been ordered.

The Timber Butte mill of the Elm Orlu Mining Co. is to be enlarged by 1000 tons daily, making a future capacity of 2500 tons.

At a depth of 1600 ft. in the Butte & London property the first 10 ft. of the new lode assays 10 oz. silver and 1% copper. A heavy flow of water has delayed cross-cutting. It is thought that the shoot is an extension of the Colusa vein of the Anaconda.

(Special Correspondence).—Contracts have been let by the Three Forks Portland Cement Co. for the erection of a 24-room hotel, store, offices, and other buildings at their new town of Hanover, 7 miles from Lewistown. The company town will have its own water-works, sewer system, lights, etc., and is expected to soon have a population of 300, as about 100 men will be employed at the plant. The new cement plant will cost \$600,000 and will have a capacity of 1200 bbl. daily. The works will be known as plant B of the Three Forks Portland Cement Co., plant A being at Trident. Plans for the machinery and plant are being completed at the general offices. The limestone for the cement will come from the South Moccasin mountains by a 14,000-ft. tram that is estimated to cost \$100,000. It is expected that the new plant will be in operation some time next year. The gypsum mill near Lewistown, also owned by the Three Forks company, is shipping 100 tons daily of exceptionally good product.

The United States Gypsum Co. announces that it will build a gypsum mill, as soon as possible, 10 miles east of Lewistown near Heath, a station on a branch of the C. M. & S. P. A spur-track will be built at once. About 25 men are employed in opening a mine on a lease of 300 acres there. The gypsum is of high grade, and occurs in a bed 11 ft. thick, of which 8 ft. is easily workable. The amount of gypsum in reserve is estimated at 7,000,000 tons.

Mining is quieter in the North Moccasins than six months ago. The orebody in the Barnes King property has proved to be narrow and of lower grade in depth. The ore from the upper levels, however, has continued of the usual grade. The

Fergus County mines have in past years been rather free of fatal accidents, but six fatalities have occurred this summer at the Kendall mines at various times from falls of rock. Two were killed at different times in the open-cut of the Kendall mine; the others in the Barnes-King. The North Moccasin, Piegan-Gloster, and Shannon mines of the company in September produced a total of \$60,600 from 6749 tons of gold ore. This is nearly double that of August.

Sutter brothers and Noble have shipped a second car of 5 tons of copper ore to the smelter at Anaconda, from their claims on Arnell's creek in the Judith mountains. The ore will average nearly 15% copper. The shaft from which most of the copper has been taken so far is about 30 ft. deep, and still in ore. The ore-shoot appears to be of the contact metamorphic type, and is 12 ft. wide. An old prospect tunnel below the shaft, said to be 200 ft. long, is being cleaned-out and will be extended in an attempt to cut the shoot in depth. If this proves successful it would prove the existence of several thousand tons of ore, and permit the mining of it more economically. A few tons of lead ore was mined and concentrated by hand from these claims 30 years ago. Recently both zinc and manganese ore has been found.

Lewistown, October 10.

SUPERIOR. Monthly profit of the Intermountain Mining Co. is now \$17,000. Crude copper ore and concentrate are shipped. Mine developments are good, and dividends are now regular.

NEVADA

GOLDFIELD. Two encouraging developments are reported from the Jumbo Extension mine, one at a depth of 770 ft., the other at 1017 ft., the deepest level.

MINA. The Drew & Farnham quicksilver mine, 14 miles east of this place, has been bonded to F. M. Manson of the Utah Ore Sampling Co., and others. A wide vein of high-grade cinnabar is said to be opened. A small furnace is treating about one ton daily, yielding two flasks of mercury.

The Silver Dyke tungsten mines in Mineral county will be closed down on November 15 owing to the impossibility of producing at a profit under present market conditions.

TONOPAH. Two transactions were recorded last week: (1) the Belmont acquired control of the Panama-Pacific ground on the east, and (2) the Extension bought the Sully property on its north boundary.

YERINGTON. At the Walker River Copper Co.'s Empire Nevada property a 20-ton leaching plant is soon to be erected. G. H. Cogswell is supervising construction.

UTAH

MILFORD. As a considerable quantity of low-grade lead-silver ore has been opened in the Antelope Star mine, 20 miles north-east of this place in Beaver county, a mill is proposed for next spring. High-grade shipping ore is being mined for the smelter.

From the Creole mine in the Lincoln district, where work was started with \$200 cash outlay, lessees have shipped 4100 tons of ore yielding \$41,304. The company now has charge, with J. M. Reynolds as manager.

TINIC. The eastern belt is more active than ever before, employing more men, and shipping lead-silver ore.

WASHINGTON

(Special Correspondence).—The largest quantity of ore ever shipped out of this district in a week was dispatched last week, the total from four properties being 1250 tons. The Lone Pine sent 700; Knob Hill, 300; Hope, 100; and Rathfon Reduction Works, 250 tons. The Last Chance mine, owned by the Lone Pine Surprise company, is to be opened by a 500-ft. shaft, already started. An L-R compressor, 85-hp. boiler, and 35-hp. Vulcan hoist are being installed.

Republic, October 11.

CANADA

BRITISH COLUMBIA

TRAIL. A year ago there were 900 employed at the Consolidated M. & S. Co.'s smelter; today there are 1600, according to H. Wright of Nelson and Trail. Ore sent from both sides of the international boundary are increasing all the time.

ONTARIO

COBALT. During September the Nipissing produced silver worth \$236,873 from 175 tons of high and 6602 tons of low-grade ores. The two mills yielded \$132,753 and \$104,120, respectively. The refinery shipped 566,703 oz. of bullion, some of it from custom ore. Development was generally satisfactory.

In the quarter ended September 30 the Temiskaming Mining Co. did 1054 ft. of development. The main shaft has reached a depth of 1325 ft. There is approximately 300 ft. farther to sink before the lower contact between the diabase and keewatin formations is encountered, when lateral development will be commenced. On the upper levels of the property work is progressing favorably. In storage, at smelters, and at the mine there is a total of 707,287 oz. of silver. Cash amounts to \$25,074. On November 22 there will be \$75,000 distributed.

Most people consider veins at Cobalt in inches, but in the Kerr Lake mine one vein is 20 ft., another 30 ft., while where No. 10, 15, and 8 veins junction the width is 100 feet.

MEXICO

NUEVO LEON

(Special Correspondence).—The alleged existence of an American zinc-trust in Mexico is to be investigated by a special commission, representing the de facto Government, to be appointed by Carranza, according to advices received here from Mexico City. It is stated that Carranza's attention was called to the combination which is said to have been entered into between the American Metals Co., Compania Minera y Compradora de Metales Mexicana, S. A., Empire Zinc Co., Compania Minera de Penoles, S. A., Compania Minerales y Metales, and Granby Mining Co. to control the price of zinc ore in Mexico, as alleged in the petition which the San Roberto Mining Co. recently filed in the district court at El Paso for \$1,900,000 damages against these companies. The complaints set forth that the defendant companies have secured control of the markets in Mexico and the United States for zinc ores "with unlawful intent to monopolize the zinc business." Men who are close to Carranza say that he has been waiting an opportunity for some time to commence proceedings with the view to ridding Mexico of the mining, smelting, and other alleged trusts that he claims are operating here. While there are no specific laws prohibiting combinations of interests for the purpose of fixing prices or restraining trade in this country, a way will be found, it is stated, for meeting the situation. It is claimed that not only the Roberto Mining Co., but many other zinc operators in Mexico, as well as miners of other metals here, have been forced to accept exceedingly low prices for their ores by the combines that control the markets. The Compania Minera y Compradora de Metales Mexicana, Compania Minera de Penoles, and Compania Minerales y Metales each operate large mines in Mexico. The mines of the Compania Minera de Penoles at Mapina, in the State of Durango, are among the heaviest producers in the country. All of these properties have been kept in operation with but slight interruption all through the revolutionary troubles.

Monterrey, October 13.

The College of Engineering at the University of Illinois, Urbana, reports that the number of students registered is 1143, out of a total of 5214 at the whole institution.

The University of California has 6400 students on the register.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

F. L. SIZER is in the Coeur d'Alene.

JESSE SCOBIE is on his way to Bluefields, Nicaragua.

GEORGE A. TWEDDY was here last week from Los Angeles.

POPE YEATMAN has returned from Cripple Creek to New York.

E. L. NEWHOUSE visited the Butte-Duluth property at Butte recently.

EDWARD L. DUFORCQ has moved his office in New York to 18 Broadway.

COREY C. BRAYTON will be in Utah and Idaho during the next two weeks.

RALPH NICHOLS has been in the Genesee district, in Plumas county, California.

W. G. MILLER and T. F. SUTHERLAND have returned to Toronto from New Caledonia.

ARTHUR JARMAN is sailing from Auckland, New Zealand, on November 3, proceeding to London.

FORBES RICKARD passed through San Francisco from Lovelock, Nevada, to Arizona, on October 24.

J. D. HELM, formerly at Mexico City, has been examining copper mines in Plumas county, California.

W. BURLING TUCKER, of the California State Mining Bureau, has moved from San Francisco to Los Angeles.

C. H. MACNUTT has obtained a commission with the Royal Canadian Engineers and expects to go overseas shortly.

A. P. ALLEN has resigned from the service of the Calumet & Hecla, and is now with the Highland Mining Co. at Ashcroft, B. C.

E. H. HAMILTON has been appointed metallurgical manager for the Trail smelter of the Consolidated Mining & Smelting Co. of Canada.

ROBERT MCGARRAUGH, formerly mine superintendent of the Aguacate mines in Costa Rica, has been promoted to general superintendent.

PERNSOR G. SPILSBURY, general manager of the Aguacate mines in Costa Rica, has moved to New York, with offices at 55 Liberty street.

J. L. MCALLEN has resigned as superintendent of the Gold Bullion mine at Knik, Alaska, and will engage in private practice at Portland, Oregon.

CHARLES W. NEWTON, manager for the Consolidated Interstate-Callahan Mining Co. at Wallace, Idaho, was in southern Idaho during the past week.

W. FRANK GRACE, manager of the Waihi Grand Junction mine, New Zealand, has been seriously ill. He has gone to Sydney, Australia, to recuperate.

F. W. SPERR, professor of mining in the Michigan School of Mines at Houghton, is at Detroit attending the fifth annual meeting of the National Safety Council.

WILL L. CLARK has resigned as manager of the United Verde Copper Co. at Jerome, Arizona. ROBERT E. TALLY, for eight years superintendent of mines for the company, is Mr. Clark's successor with the title of assistant-general manager.

W. C. MADGE arrived at Spokane on October 17 from the Ridder mining concession, Siberia. He will be in America for about a month, after which he returns to London to the headquarters of the company, the Irtysh Corporation, Limited.

F. N. FLYNN, for the past seven years connected with the Arizona Copper Co. at Clifton, on October 31 resigned his position as superintendent of the smelting department. ROGER H. HATCHETT, who has been Mr. Flynn's assistant for six years past, has been appointed acting superintendent of the department. Mr. Flynn sails early in November from New York to Chuquicamata, Chile, where he will enter the employ of the Chile Exploration Company.

THE METAL MARKET

METAL PRICES

San Francisco, October 24

Antimony, cents per pound	14.00
Electrolytic copper, cents per pound	29.25
Pig lead, cents per pound	7.25—8.50
Platinum: soft and hard metal, per ounce	\$90—91
Quicksilver, per flask of 75 lb.	\$89
Spelter, cents per pound	12
Tin, cents per pound	42
Zinc dust, cents per pound	20

ORE PRICES

San Francisco, October 24

Antimony, 50% metal, per unit	\$1.00
Chromite, 40% and over, full cars California, per ton	13.00—16.00
Magnetite, crude, per ton	8.00
Manganese, 50% (under 35% metal not desired)	14.00 and up
Tungsten, 60% WO ₃ , per unit	17.00—20.00

New York, October 18

Antimony. Quotations are unchanged at \$1.10 to \$1.25 per unit, but nothing is stirring in the absence of arrivals.

Molybdenum. The supply of ore is small and uncertain. The quotation is unchanged at \$1.50 to \$1.75 per lb. for molybdenum sulphide.

Tungsten. The market continues active, with Europe the principal buyer. All told, several hundred tons have changed hands. High-class material is quoted at \$17 per unit, but inferior ore has been sold at \$11.50 to \$15. The market for ferro-tungsten is active, export inquiries in particular being numerous. It is quoted at \$2.70 per lb. of contained tungsten.

EASTERN METAL MARKET

(By wire from New York.)

October 24. Near-by copper is scarce, and futures are fairly active, lead is quiet, though strong, for spelter galvanizers are active, but sellers are reserved.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
Oct. 18	67.25
" 19	67.25
" 20	67.25
" 21	67.25

May	58.21	49.87	74.27
June	56.43	49.03	65.04

While the past week's prices show a downward trend, the tone is good. Samuel Montagu & Co. write to the London market that it is a singular fact since the middle of July, when silver may be said to have recovered from the shock of the devaluation last May, when it was announced that the Allies had wisely decided not to make their purchases of gold in competition with each other, that prices have been steadily on the new high figure when that has not been a general rule.

On the 21st silver worth \$132.95 was sent from San Francisco to California. Stock at Shanghai is now 1,000,000 oz. In bars, a reduction of 100,000,000 oz. has been ordered to India.

May	13.97	18.71	29.92
June	13.60	19.75	27.47

Refinery production of the country during September totaled 160,000,000 lb. This is a slight recovery, but 30,000,000 lb. below the May yield. It is estimated that the year will produce 2,100,000,000 lb., an increase of 28%.

Kennecott in September produced 8,000,000 lb., a decrease of 2,200,000 lb.; Old Dominion, 3,011,000 lb.; Granby, 3,440,035 pounds.

Apart from the claim by Russia of \$1,140,000 against the Tennessee Copper Co., and other claims in dispute, the company owes banks and others \$1,500,000. Since January 1, 1915, over \$2,500,000 has been spent on new plant. A new stock issue is being made to pay off this debt.

Eastern Metal Market

New York, October 18.

Quiet has been the chief characteristic of the market, a condition that some members of the trade attribute to the recent raids by a German submarine off the New England coast, but which probably is quite as much due to the fact that heavy buying cannot go on forever. Consumers are covered, some of them well into next year, therefore they stop buying.

Copper continues dull, though strong.

Zinc has declined a few points, but producers are satisfied with the manner in which it has resisted any radical decline.

Lead is quiet and steady, with all interests quoting near the same level.

Tin is easier because of selling by small holders who thought it best to take their profits.

Antimony has been more active on Canadian account, and its quotation is higher.

Aluminum is easier following a cessation of export buying. The steel mills continue overwhelmed with the demand for ship plates, many thousand tons of which are wanted on the Pacific Coast. For these plates, 4 to 4.50c., Pittsburg, is asked, whereas ordinary tank-steel can be had at 3.50 to 4c., Pittsburg. Marine-boiler steel is quoted up to 8 and 10c. per lb., Pittsburg. Structural shapes are quoted at 2.85c., Pittsburg, but 3.50 is asked for ship shapes. Steel bars are around 2.70 to 2.75c., Pittsburg. How the high cost of structural shapes and other building materials is halting new construction is evidenced by the September report of the Bridge Builders and Structural Society (made up of independent fabricators), which shows that the business taken by its members in that month amounted to only 52½% of capacity, against 64% of capacity in August. Despite this interesting statement, there is ample opportunity to dispose of every pound of steel the country can produce. An unprecedented quantity never gets to the finished stage. Pig iron continues to gather strength, not only because of demand but because of increased cost of production. Coke is scarce and high because of insufficient cost of production. Coke is scarce and high because of insufficient labor in the coke-making districts and a shortage of freight-cars wherewith to transport the product. As a result, blast-furnace managers have been compelled to enter the open market for spot coke and some have paid \$5 per net ton at oven.

Makers of machine-tools continue to advance prices, although the full tide of war business has passed, and their dealings are now principally with domestic industrial buyers. It is difficult to point to any commodity that is not higher in price.

COPPER

Prices are steady, but the market is dull, and features of interest are wanting. Large consumers have covered their requirements for the remainder of the year, and many have done so for the first quarter of 1917. Consumption is going forward on an enormous scale in brass and copper-rolling mills, munition plants, and wherever copper is used. Hot-rolled sheet copper is quoted at 37.50c. per lb., delivery at mill's convenience; cold rolled at 38.50c. Copper rods are quoted at 43c., and copper wire at 32.50 to 33c., according to delivery. Brass sheets range from 42 to 46c., and wire and light rods from 45 to 48c. Electrolytic copper is quoted at 28.50 to 29c. for nearby delivery. November and December at 28 to 28.25c., and first quarter at 27.25 to 27.50c. Lake, for nearby delivery, is a shade under electrolytic. But little copper is held by second hands, and it is predicted that they will endeavor to depress the market in order to acquire the metal advantageously. The producers are so well sold-up, however, that prices are likely to remain steady for some time.

As heretofore said, the elimination of the Allies from the market for many months will have a steady influence. The London market is unchanged at £143 (for electrolytic), compared with £142 a week previous. Exports this month, up to and including October 17, total 11,052 tons. Stocks in Great Britain and France, on the 15th totaled 5620 tons, against 5796 tons on September 30. Including the stocks from Chile and Australia, the total European supply, on October 15, was 10,670 tons, against 10,371 tons at the end of September.

ZINC

In a quiet way a fair but not large business in spelter has been done. Prices are a little lower, although they have resisted the tendency to decline in a manner considered satisfactory by sellers. Prices quoted yesterday for October and November were about 9.62½ to 9.75c., New York, and 9.50 to 9.62½c., St. Louis. There is some show of interest on the part of the brass mills, but they have yet to take hold in a way that will mean business—and higher prices. The export demand is not heavy. Producers say consumption is nearly keeping pace with production. One of the puzzling features is that the galvanizers are known to be operating far below capacity, some estimates placing the rate of operation at about 35%. There can be no question as to the consumption of spelter, and the real question is—where is it going? Exports, of course, continue heavy, amounting this month to date to 4645 tons. The London quotation yesterday was £53, against £56 a week previous. The quotation for sheet zinc in car-load lots, is unchanged at 15c., f.o.b. mill, 8½ off for cash.

LEAD

The dull but steady market has remained unbroken, and neither independents nor the leading interest have made any change in their quotations. The A. S. & R. Co. quotes 7c., New York, and 6.92½c., St. Louis, while the outsiders ask 7c., New York, and 6.85c., St. Louis. Reports were current yesterday of a betterment in demand, but if it existed it could not be easily found. The general observation is that consumers are content merely to watch the market, while producers show no anxiety to sell. The London quotation yesterday was £30 10s., against £30 15s. a week previous. Exports to the 17th totaled 2412 tons. Government statistics recently issued show the total production of lead in the United States in 1915 to have been 550,055 tons, the largest on record, comparing with 542,122 tons in 1914, and 462,460 tons in 1913. Last year's production consisted of 388,594 tons of desilverized and 161,461 tons of soft lead.

TIN

A desire on the part of small holders to take profits has made prompt tin easier. The easiness was helped along by the arrival of steamers with considerable stock, one boat, the *City of Naples*, from Singapore, bringing 450 tons. On one or two days fair sales were made, but for the most part the week has been a quiet one. Most of the buying involved futures, and included Banca tin for November shipment from Batavia. The differential between Straits and Banca is not as wide as usual. Spot Straits was quoted yesterday (the 17th) at 40.75c., whereas spot Banca could be had at 40.50c. Most of the Banca is firmly held by London houses, despite its Dutch origin. The arrivals this month total 1630 tons, and there was afloat yesterday 1900 tons.

ANTIMONY

Canadian interests are reported to have taken several hundred tons of Oriental brands, in bond, last week, with the result that considerable strength was imparted to the market. Current quotations range from 13 to 13.50c., duty paid.

Mining Decisions

SEVERANCE OF MINERALS—SUBJUNCT SUPPORT

Where a land-owner conveys the surface of land reserving to himself the right to mine and extract the coal and other minerals underneath, the grantee of the surface is entitled to subjunct support of his land and the owner of the mineral rights must leave enough pillars to furnish such support.

Stonestap Colliery Co. v. Hamilton (West Virginia), 89 Southeastern, 305. June 8, 1916.

OIL LEASE—LESSOR'S ELECTION OF REMEDIES

Under the terms of an oil lease the lessee was required to drill a well or pay \$50 per month rental in lieu thereof. On his failure to do either the lessee might elect to either forfeit the lease or sue for rentals thereunder as they became due. Until a forfeiture was formally declared or a release made after notification by the lessee, the lessor was at liberty to pursue his action for rentals accrued but not paid.

Clemenger v. Flesher (Texas), 185 South-western, 304. March 18, 1916.

OIL AND GAS LEASE—LESSOR'S REMEDIES

Where an oil and gas lease provided that the lessee thereunder should complete a well within six months from the date thereof, or pay the lessor rental at the rate of \$20 per month, the provision is for the benefit of the lessor only, and he alone may elect whether to cancel and terminate the lease or to stand on its terms and sue for rentals due up to the time the premises are re-conveyed or until the term expires.

McKee v. Grimm (Oklahoma), 157 Pacific, 308. May 16, 1916.

PETROLEUM WITHDRAWALS—SUBSEQUENT ENTRY

Petroleum lands that had been withdrawn from entry by order of the President of the United States prior to an actual discovery of oil thereon are the exclusive property of the Government. Oil companies who entered thereon, and discovered and extracted oil subsequent to such withdrawal order, under leases from persons who had made paper locations prior to the date of said order were held to be trespassers, were perpetually enjoined from further operation, and were required to account to the Government for the value of oil already extracted, less the cost without profit of extracting the same.

United States v. Midway Northern Oil Co. (California), 232 Federal, 619. May 1, 1916.

EXTRA-LATERAL RIGHTS—PROOF OF APEX

When the apex within a claim is terminated by a fault, such a termination limits the boundaries of the extra-lateral plane unless the apex recurs on the other side of the fissure and within the boundaries of the claim. Where the determination of the apex issue rested upon expert testimony as to the classification of the mineral found in the apex as quartzite or limestone and such determination could only be had through microscopic examination, the Court will not substitute its own judgment based on a personal examination of the ground in dispute for the testimony of experts even though the latter be in conflict. The limestone zone lying between a hanging and a foot wall of quartzite was held to be a broad vein or lode apexing in defendant claim, and lying a well-defined continuant, to and including the orebody. In dispute.

Wall v. United States Mining Co. (Utah), 232 Federal, 619. May 1, 1916.

Industrial Notes

Information supplied by the manufacturers.

A New Model Little Tugger Hoist

For the use of those who prefer manila rope to wire rope for light hoisting and hauling, the Ingersoll-Rand Company of New York has devised a new model 'Little Tugger' hoist which is designated No. 11.

The square piston, reversible driving engine, automatic lubrication, enclosed gearing, drum-release clutch, and worm-

THE NEW LITTLE TUGGER HOIST.

operated hand-brake are essentially the same as in the No. 1 model, which was described on page 624 of the PRESS of October 17, 1914. The main differences are in the diameter and length of the drum, the width of the flanges and, necessarily, the main frame and overall dimensions. The new No. 11 has a hoisting drum 7 in. diam. by 17 in. long, with 5-in. flanges. This accommodates 300 ft. of $\frac{3}{4}$ -in. manila rope. The maximum capacity of this hoist is conservatively rated at 600 lb. The weight of the hoist itself is 358 lb. It is 21½ in. long, 31¼ in. wide, and 23 in. high. Like the No. 1, the No. 11 machine is designed for operation both by compressed air and steam. The standard clamp fits a 1½ in. diam. column or pipe, but by removing the clamp the hoist can be readily bolted directly to any convenient support, timber, or flooring.

Although designed primarily for underground work, it is recommended by the manufacturer for general hoisting, hauling, and handling in mines, tunnels, quarries, and industrial plants.

P. H. RIMMOX desires to announce that he has disposed of his entire interest in General Machinery & Supply Co. and that, pending the occupancy of permanent quarters, he has opened temporary offices in the Hooker & Lent Bldg., 503 Market St., San Francisco, for the purpose of engaging in the business of compressed air and general machinery, specializing on prompt and efficient service for everything pertaining to mine equipment and supplies. Correspondence is solicited. On and after November 15 the firm will be established in its permanent office at 57 First street, San Francisco.

The General Electric Co. is now manufacturing a new type time limit over and relay of single-pole design. It is said to be particularly applicable to those systems where extreme accuracy in timing is required for tripping two or more air or oil circuit breakers collectively.

EDITORIAL

T. A. RICKARD, Editor

FORTY-ONE pesos are needed to buy one American dollar. This matter of exchange is paralyzing business in Mexico. Meanwhile Carranzistas, Legalistas, Zapatistas, and Villistas are exhausting the life of the country without any promise of a combination of parties to restore order.

EQUANIMITY marks the public temper on the eve of the Presidential election. It is not believed that the result will affect the general prosperity, which is today influenced mainly by events outside the United States. The one thing to cause violent perturbation would be the cessation of hostilities in Europe. When that comes we shall see a sharp break in the price of metals and a rise in the price of cotton. What the further effects will be nobody knows; the prophets were stultified by their predictions at the beginning of the War.

DIRECTORS of Stratton's Independence, Ltd., the English company that formerly owned the famous mine discovered by W. S. Stratton at Cripple Creek, were given four months in which to find a new property "in one of the Allied countries, preferably Russia." We learn that the search for a fresh venture has ended in an arrangement to participate in a new enterprise known as the Altai Concessions. The Altai is a mineral region that is sure to attract increasing attention. We published an article on this part of Siberia by Mr. H. W. Turner in our issue of June 26 last year.

ON another page we give reasons for labeling the New Modderfontein the greatest gold mine in the world. Since that editorial was written we have received the company's report for the year ending June 30, 1916. This confirms all that we have said and therefore calls for no corrections. The profit earned in the last fiscal year was £766,200, as compared with £692,100 in the previous year. This gain was due largely to an improvement in the yield to 40s.10d. or \$9.90 per ton. New ore 'developed' during the year amounted to 1,764,000 tons averaging 11 dwt. per ton, and the reserve was increased to 8,013,400 tons, averaging 8.4 dwt. per ton. Delay in the delivery of machinery will prevent the completion of the new plant until the end of next year.

LOSSES and gains due to the War are difficult to appraise. One source of loss is not appreciated: the decline of immigration. We are losing a million immigrants per annum owing to the War in Europe, where

30,000,000 people have been under arms for two years. Each immigrant into the United States is estimated to increase the national wealth by an amount ranging from \$500 to \$1000 annually, so that the check to immigration is costing us about \$750,000,000 per annum. Nobody knows what will happen when the War ends: whether emigration from Europe will be resumed in its former volume or not. The general surmise is that England, Germany, and France will retain their people but that Poland, Hungary, and the Balkan countries will emit a large flood of unfortunates across the Atlantic. In any event, a great shock to the labor market is inevitable when hostilities cease, and with it will come a re-opening of the entire labor problem.

WE have received a circular letter signed by a group of distinguished members of the engineering profession asking us "to call attention to the importance of electing a Republican administration in November." That we cannot do, because this is a non-partisan paper. The interest of our readers in Mexican mining affairs, however, is so large that we feel justified in quoting the statement made by Mr. Hughes: "An American in Mexico is subject to Mexican law, but he is an American still and is entitled to the protection of his own government in his lawful business. For one, I shall never consent to a policy which leaves Americans helpless against the lawlessness of any country in which they have a right to do business." We were glad to read this statement of policy by the Republican candidate and we hope the time may come when it will cease to be a political issue.

PAPER has risen so much in price that the newspapers have been compelled to reduce their bulk. Recently the New York Times, truly a splendid newspaper, announced that it had to omit 24 columns of advertisements. The crisis in the paper market may prove a not unmixed evil if it leads to an abatement in the lavish printing of silly supplements and society flapdoodle. Even the technical press, which is relatively far less voluminous, might learn a lesson. The average reader, especially among the younger men, does not realize how much his technical paper has increased in size during the last 20 years. Some of that increase represents a gain of information, but a part of it, as in the daily newspaper, is only padding. In this matter the public taste has been spoiled; bigness is mistaken for worth, a mere mass of printed matter is confused with value received in the form of intelligent comment, interesting

descriptive matter, or current news. One result has been the submergence of the technical man under a flood of half-baked indigestible print, against which he hardly knows how to protest. Engineers talk a lot about efficiency, but they fail to realize how inefficient the technical literature of the day has become. Perhaps the paper famine will serve as a salutary discipline.

FRENCH and American mining companies in Korea are having trouble over the labor question. The Japanese are claiming the right to supply the necessary labor; in other words, to sell labor under a contract that prevents the European management from dismissing its employees at will. At the Nampui mine, on the French concession, this labor contract was opposed until recently, when the manager was forced to accede to the demands of the Japanese, at the point of a gun. At the Tul Mi Chung mine, of the Seoul Mining Company, a serious crisis was reached during the first week of October. A number of low-class Japanese had been trying to persuade the management to allow them to supply labor under contract. After sundry interviews, these Japanese threatened the manager, Mr. W. T. Hall, and later swore to kill him and the company's interpreter, a Japanese, and also Mr. A. R. Weigall, the consulting engineer. Fortunately a number of Japanese in the employ of the company proved loyal and the other members of the American community, being forewarned, were able to arm themselves so as to prevent attack. On the same day an attack was made on the bullion escort from the Oriental Consolidated, and Mr. Wellhaven, a brother of Mr. Alf. Wellhaven, the general manager, was killed, while Messrs. Williams and Barstow were wounded. The company policeman and the driver of the buckboard were also killed, but the bandits did not get the bullion. It is hoped that the Japanese government will realize its responsibility and put an end to this continued threat against the Korean mining companies that are operating legally under its benevolent sanction.

TESTIFYING before a Government commission at Johannesburg, Mr. R. N. Kotze, until recently the Government Mining Engineer, states that the chief drawback to the State undertaking mining operations was the possibility of financial loss, as it could not be presumed that all the areas in the East Rand would prove profitable. The State would be unable to make as large a profit as an individual or company, nor would it be able to command the highest technical talent on the usual Governmental salaries. Political interference would be another objection; also the probability of disputes with employees. Finally, he suggested that the absence of the share market as an element in State exploitation of the gold mines would enormously restrict enterprise. Much sagacity is to be detected in this testimony. Of course, the share market always affords an avenue of escape for the incubator of an unfortunate mining enterprise, giving him a chance to pass his 'investment' to simple-minded persons not aware to the

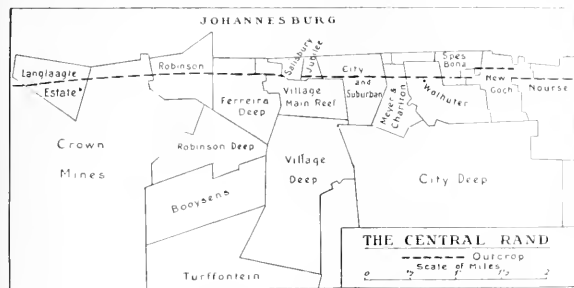

realities of the 'game.' If everybody went into mining like a State acting under the advice of Mr. Kotze, there would be less money wasted on worthless projects and less inflation of shares when a rich mine was uncovered. As it is, between the essential risks of a speculation, such as a mine always is, and the probability of buying at an inflated valuation, the average member of the public is likely to get off on the wrong foot. If the 'big houses,' or financial corporations controlling mines, such as those of the Rand, were to keep their shareholders, and through them the public, faithfully informed concerning the true conditions governing the profitable productivity of their operations, in other words, if directors would act like trustees, then the chances of making money out of mining would be increased for the shareholders or the public and decreased for the clever—or 'slim' as they call them in South Africa—financiers. On the other hand, 'the possibility of financial loss' would deter the State from making many a reasonable venture. That possibility of loss is inherent in mining, because mining is essentially venturesome. We do not expect to remove that essential quality, for it is one that pertains to a business that is as risky as it may be profitable. On the Rand, unfortunately, the risk is too much one way. A mine may do less than is expected of it, but it is unlikely to do more. That is the drawback to the 'sure thing' in mining. In ordinary vein mining, with possibilities in depth and the probability of discovering new ore-bodies, or even a big bonanza, in the course of intelligent exploratory work, there is the chance of a pleasant surprise. On the whole, it is not good business to buy ore in reserve; the best fun in mining is in the sport of finding ore and in the opportunity to strike it so rich that tables of amortization assume an academic aspect. The State is too old and too timid to enjoy that game; it is the privilege of the true adventurer, of him that is willing to put all to the touch and penetrate into the unknown.

The Greatest Gold Mine

Nine years ago, in May 1907, when passing in review the leading gold-producing mines of the world, we came to the conclusion that the three best mines were the Robinson, the Waihi, and the Homestake. The Robinson was at that time the premier property on the Rand gold-field; it had 4,500,000 tons of \$14 ore assured and was being operated at a cost of \$4.90 per ton. The stoping width was 6½ feet and only 18% of waste had to be sorted out of the mine product. Finally, the mine was earning \$3,500,000 per annum. This, it will be granted, was a handsome showing. What has happened since then? In 1915 the mill treated 688,800 tons of 6.72 dwt. ore at a cost of \$3.40, after sorting out only 3.7%. The yield in gold was worth \$1,652,389 (£1 being taken at \$4.85) of which \$2378,692 was labeled profit. The dividend was \$1,915,750. Nine years ago the mine had paid \$25,197,362 on a capital of \$13,750,000. Since then it has produced 5,280,460 tons yielding \$55,069,060, av-

eraging \$10.43 per ton. On this a nominal profit of \$35,373,194 was declared and \$28,738,263 distributed in dividends, equal to 24% per annum during the nine years, on a capital of £2,750,000 or \$13,337,500. Evidently therefore the Robinson has fulfilled expectations. From the beginning of 1888 to the end of 1915, this mine has produced £20,480,945, equal to \$99,332,584, from 7,966,775 tons of ore, averaging \$12.50 per ton, at a cost of \$4.43 per ton. The dividends aggregate 405½%, or \$54,235,625, in 27 years, or 15% per annum on the 550,000 shares of £5 each. Incidentally, the aggregate 'profit' is just about \$10,000,000 less than the total of dividends. During the first year, 1888, the ore averaged 3 oz. gold per ton; just before the Boer War, in 1899, the average was 17 dwt.; and in 1912, when the richest layer of banket, the Leader, was approaching exhaustion, the average fell to 10½ dwt. per ton. In the 27 years the cost decreased from \$14.45 to \$3.40. Now there remains 565,100 tons of about 10 dwt. ore in the Leader and South Reef, besides 400,000 tons of 4.4 dwt. stuff in the

owning the ground ahead of it on the dip, so that it possessed chances of further discovery in depth—and the risk of disappointment. The Robinson, so it seemed to the present writer nine years ago, was "more nearly an investment, while the Waihi"—we said—"is a most attractive speculation." To this we added: "As all experience proves that persistence in depth is hazardous and as the bottom of the Robinson's ore measures are known and those of the Waihi are unknown, the choice is between the assured and the possible, where both are sumptuous. We accept the responsibility and label the Robinson the greatest gold mine in the world." The choice between the two great mines has proved correct. The Waihi did have bad luck in depth, and this bad luck, being accompanied by over-valuation of the shares and delay in making known the fact of impoverishment on the lower levels, caused a fiasco of a sensational and disastrous character. The quotation on 500,000 shares dropped from \$50 to \$14.50 within twelve months and is now at \$8.50, indicating a fall of \$20,212,750 in the market valuation. The episode reflects discredit on the directors in London; for either they were ignorant concerning facts that were known at the mine or they were aware of the truth and failed to advise the shareholders with reasonable promptitude. The Waihi must have caused a great loss of money to the public, as always happens when rich mines are wildly over-valued. In 1915 the mine produced 192,333 tons yielding \$1,689,230, of which \$753,724 was profit and \$481,000 was dividend, this being at the rate of 20%, so that on its original capital of £500,000 the mine is still doing respectably. But the

Main Reef. This includes packs, pillars, and remnants of ground. Thus the mine has enough ore to extend its life into the middle of 1917, by which time it will have produced over \$100,000,000 in gold. Then it will be definitely finished, for the property has been completely 'developed,' that is, all the area vertically under the claims has been explored and will be exhausted. By the laws of the Transvaal there is no extra-lateral right to mine on the dip beyond the side-line, the lode in the Robinson having been already mined on its dip by the Robinson Deep, which as a 'deep level' has proved a worthy second to its corresponding 'outcrop' property. So the Robinson has made good; it does honor to its successive managers, the late Capt. Thomas Mein, his son Mr. William W. Mein, and the present manager, Mr. Palmer Carter.

Discussing the relative merits of the Robinson and the Waihi in 1907, we emphasized the fact that the resources of the Robinson were known accurately, because not only was it well explored and sampled, but the workings of the mine below it on the dip had tested the deepest ground that it had the right to work. The Robinson had no possibilities in depth, but it also lacked the chances of sudden impoverishment. On the other hand, the Waihi, with reserves only a quarter those of the Robinson, had the right to follow the lode indefinitely in depth,

owning the ground ahead of it on the dip, so that it possessed chances of further discovery in depth—and the risk of disappointment. The Robinson, so it seemed to the present writer nine years ago, was "more nearly an investment, while the Waihi"—we said—"is a most attractive speculation." To this we added: "As all experience proves that persistence in depth is hazardous and as the bottom of the Robinson's ore measures are known and those of the Waihi are unknown, the choice is between the assured and the possible, where both are sumptuous. We accept the responsibility and label the Robinson the greatest gold mine in the world." The choice between the two great mines has proved correct. The Waihi did have bad luck in depth, and this bad luck, being accompanied by over-valuation of the shares and delay in making known the fact of impoverishment on the lower levels, caused a fiasco of a sensational and disastrous character. The quotation on 500,000 shares dropped from \$50 to \$14.50 within twelve months and is now at \$8.50, indicating a fall of \$20,212,750 in the market valuation. The episode reflects discredit on the directors in London; for either they were ignorant concerning facts that were known at the mine or they were aware of the truth and failed to advise the shareholders with reasonable promptitude. The Waihi must have caused a great loss of money to the public, as always happens when rich mines are wildly over-valued. In 1915 the mine produced 192,333 tons yielding \$1,689,230, of which \$753,724 was profit and \$481,000 was dividend, this being at the rate of 20%, so that on its original capital of £500,000 the mine is still doing respectably. But the shareholders who bought at \$50 per share will hardly be satisfied with a 2% return on a venture now known to be hazardous. The reserve of ore is estimated at 806,000 tons, besides 673,900 tons in pillars and remnants. The mine is now 1470 feet deep.

In 1907 we stated that the reserves of the Homestake were not known, but they were supposed to be "sufficient for at least twenty years, that is, over 30,000,000 tons." Dividends of \$22,134,840 had been paid up to then, which was 30 years after the company started to work. The workings were 1400 feet deep, but stoping had been extended only to 1000 feet. The low grade of the ore, \$3.85 per ton, and the small margin of profit over the cost, which was \$2.73, was a factor of danger and caused us to prefer the Robinson and the Waihi. During the nine years since that was written, the margin over cost has been widened, the yield last year having been \$4.08 and the cost \$2.65. In the interval the mine has yielded \$53,771,793 out of which \$14,046,840 has been paid in dividends. To the end of 1915 the Homestake Mining Company, which was incorporated on November 5, 1877, by J. B. Haggin, George Hearst, and Lloyd Tevis, had produced \$140,610,382 in gold, from which \$35,615,908 had been distributed in dividends to the shareholders. In the year 1915 the output was 1,573,822 tons, averaging \$4.08, at a cost of \$2.65 per ton. The production of

ore has been increased 10,000 tons per month since 1907, so that the gross output has been augmented by about \$1,500,000 and the dividends by \$1,000,000 per annum. In 1914 Mr. Richard Blackstone succeeded the late Thomas J. Grier as manager. During later years the technical policy appears to have become more progressive. What reserves of ore the mine may have is not known. It is reputed to have enough for 30 years, but the only official information available is the statement by the manager appearing in the last annual report informing

the principal gold-bearing member of the series is the Main Reef Leader, an extremely persistent bed of conglomerate, which in the Brakpan mine averages 6.7 dwt. gold per ton; in the New Modderfontein, 8.2; in the Modderfontein B, 8.6; in the Government Areas, 6.5; and in the Springs mine, 10.5, so far as determined, for a stoping-width of about 5 feet. In this part of the district the dip of the strata and the included ore ranges between 8° and 22°.

The New Modderfontein and Modderfontein B are contiguous outcrop mines, with the Van Ryn Deep, the Modderfontein Deep, and Government Areas as their corresponding 'deep-levels.' The New Modderfontein property includes 1265 claims, or 1860 acres, of ore-bearing ground. The purchase entailed sums aggregating \$2,454,325, a part of the consideration being an annuity of \$8,950 for 20 years. The company was organized in 1888 and started milling with 10 stamps four years later. In 1896 a new 60-stamp mill was built and by 1909 the number of stamps had been increased to 180, assisted by seven tube-mills. A second mill is now being erected, so as to bring the crushing capacity to 90,000 tons per month. During the year ended June 30, 1915, the mine produced 738,300 tons, of which 17% was removed as waste, leaving 611,800 tons for the mill, where 184,208 ounces of gold was extracted by amalgamation and 94,678 ounces by cyanidation, the total gold being worth \$5,616,324, equivalent to \$9.18 per ton. The working cost was \$3.82 per ton, so that the profit was \$3,314,738, from which dividends amounting to \$2,121,875 were paid, equivalent to 31 1/4% on a capital of 350,000 shares of £4 each. The development and equipment of the mine has involved an outlay of \$6,937,921. Henceforth all such expenditures will come out of revenue account. The ore already proved is estimated at 6,000,000 tons, averaging 8.15 dwt. per ton, besides 1,000,000 tons of 'partly developed' ore. But this does not begin to measure the resources of the mine. Possibilities become strong probabilities in the light of evidence obtainable from the workings of the adjacent property—the Modderfontein B—and from workings deeper on the dip in the Modderfontein Deep and Van Ryn Deep mines. In June last year 169 claims out of the 1265 had been worked out, yielding 31,940 tons per claim, so that the possibilities of further production are enormous. Deducting 20% for faulted areas, 15% for sorting, and allowing a net stoping width of 48 inches, the ground remaining should yield 19,000,000 tons. Crushing at the rate of a million tons per annum, the life of the mine should last about 20 years and it should produce \$125,000,000 more. From June 1895 to June 1915, exactly 20 years, the New Modderfontein has produced 1,816,680 tons, yielding 1,950,553 ounces of gold, worth \$3,745,076, of which \$17,860,023 has been 'net profit' and \$12,247,250 dividends. The shares are quoted at \$82.50. This is today, we believe, the greatest gold mine in the world, as measured in known resources and assured profits.

the shareholders that "the measured ore reserves are large and sufficient to supply the reduction plants for many years." About 2,000,000 tons of ore is said to be stored underground. In default of the essential information concerning the resources of the property, it cannot be appraised nor can it be compared with other great mines. But whatever it may accomplish in the future, the Homestake has already established its position as the most persistently profitable low grade gold mine ever exploited by man.

Since 1907 a group of big and highly productive mines has been developed in the eastern end of the Rand or Witwatersrand, to give the goldfield its proper name. In that locality the Main Reef Series, as the gold-bearing beds of conglomerate are called, has a dip flatter than in the Central Rand, where are, for example, the Robinson, Simmer & Jack, and Village Main Reef, mentioned in this or in a preceding article. In the Far East Rand

A Journey to British Columbia

By T. A. Rickard

This will be a non-technical article, so I warn my readers that they may find nothing of immediate use to them, but if they care to see something of the human side of a beautiful mining region they can sail with me on the steamship *Governor* from San Francisco to Victoria, the capital of British Columbia.

The approach to any country from the sea is more impressive than the entry overland. Railways take the traveler through intermediate stretches of transition and usually bring him to his destination through the bedraggled outskirts of big cities, but to the voyager by sea is given all the charm of the unexpected: after a few days of monotony on the trackless waters he sees a new land on the horizon; he glides into a beautiful harbor—for all harbors are lovely to the seafarer; he enters a strange city through its water-gate, which is always romantic; finally he lands in a community so unlike the one he has left that it seems as if he had discovered a new world. Such are the ideas that would be uppermost in the mind of any observant man or woman from California on arrival at Victoria. The distance is only 740 miles and the time spent on the voyage is only 50 hours, yet the change of scene, of climate, of people, is vivid. On landing one hears the official language of the United States spoken with strange accents, one sees the British policeman—the ‘bobby’—at the street corners, and the martial Highlander swings past in his kilt. There are more horses on the streets than in San Francisco, there are more men in khaki, and in the stores (or ‘shops’) one receives a ‘Thank you’ with unexpected frequency.

The harbor reaches to the heart of the city. There the imposing Parliament buildings and the handsome hostelry of the C. P. R. (nobody says ‘Canadian Pacific Railway’) are surrounded by lawns of vivid green, for rain is almost as frequent as in England, and to one leaving California in the dry months the season seems much behind. The population of Victoria is only 48,000; it can claim no importance as a commercial centre, but it is a delightful place of residence, and of homes, with Government House, the seat of the Lieutenant-Governor, as the social nucleus.

It was a sunny day when we (not the editorial but the domestic ‘we,’ for my much better half was with me) landed. A stroll along the main thoroughfare—Government street—suggested business depression, in part the sequel to a ‘busted’ real-estate boom but in large measure due to the preoccupation of war. Returning, the view was fine: on the right the harbor with its shipping, on the left the Empress hotel, in front the ornate pile of the Parliament buildings, and beyond them the snow-capped summits of the Olympic range, on the United States mainland, across the strait of Juan de Fuca.

Anybody interested in mining goes, on arrival at Victoria, to see Mr. William Fleet Robertson, the Provincial Mineralogist, who will be found rich with information and generous in the giving of it. The position he holds is more important than that of State Mineralogist on our side of the line because it is non-political and is therefore held by a good man for a long term of years. Mr. Robertson’s predecessor was Mr. William A. Carlyle, (McGill, class of ’87) afterward manager at Rio Tinto, later professor of metallurgy in the Royal School of Mines, London. But Mr. Robertson has held the post since 1898, so that he has his own background. A graduate of McGill University, in the class of ’80, he obtained his first professional experience with the Orford Copper Company and then served as superintendent for that great Canadian, James Douglas, at the Phoenixville copper plant in Pennsylvania. There the Hunt & Douglas process, a metallurgical landmark, was tried, soon to be replaced by the smelting and refining of Western matte, for the early leaching processes proved too expensive, faring ill when compared with the electrolytic methods evolved in these later days of cheap electricity. In 1881 the Orford company leased the Phoenixville plant before building the more celebrated smelter at Constable Hook, much to the annoyance of the good people on Staten Island, New York. Henry M. Howe, the authority on ferrous metallurgy, was manager and Mr. Robertson was superintendent. It was in 1880 at Capelton, in Quebec, that Professor Howe got his idea for the ‘large blast-furnace,’ as it was then called. The Orford people had leased the Capelton plant from an old Scottish company, which had erected a row of copper blast-furnaces, 4 by 4 ft. inside. In the course of operations a copper bottom rich in gold had accumulated in two adjacent furnaces. By the terms of the lease, it was not permissible to tear down anything, whereupon Howe walled the space between these two furnaces, making one 15 ft. long. The ground sloped so that a low tap-hole could be used in the new wall. This enlargement proved so successful that the Orford works at Eustis (a mile from Capelton) started with furnaces 4 by 11 ft. inside. This development was the kind of ‘accident’ that befalls a resourceful man; it was the forerunner of the much bigger blast-furnaces, also composite, built by E. P. Mathewson (McGill, class of ’85) at Anaconda. Besides these metallurgical reminiscences Mr. Robertson gave me an outline of the conditions governing the mining industry of the Province. The past year had shown a gratifying increase in the production of metals, ascribed not so much to fresh discoveries as to the expansion of established enterprises. A further increase in the output was assured, he said, for 1916, in conse-

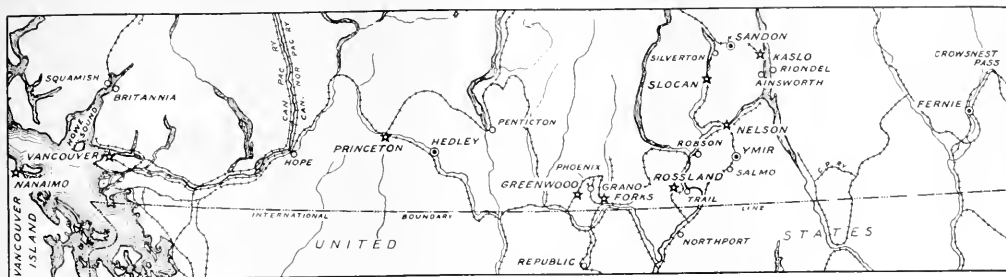

quence of the rush to obtain the benefit of high prices for metals.

Next day, in the afternoon, we sailed on the *Princess Charlotte* for Vancouver, a voyage of 80 miles accomplished in 4½ hours. The steamer threads her way among fir-clad islands, passing through the narrows of Active pass, before crossing the broader expanse of the inland sea, called Gulf of Georgia, that separates Vancouver island from the mainland, to which the city of Vancouver is the Canadian port of entry. This city stands, not on the estuary of the Fraser river, as might be inferred, but on an inlet or 'sound,' resembling those of New Zealand or a Norwegian fiord. On the right—which is south—is a richly wooded peninsula; on the left is the dark mass of the Cascade range, half-veiled in mist. The steamer makes for the Point Atkinson lighthouse and then turns abruptly to the right into Burrard inlet, the harbor of Vancouver, which, with its jagged sky-line of tall buildings, looks like a miniature New York set amid primeval woods and lordly mountains. Here also the traveler rests at a C. P. R. hotel, 'The Vancouver,' which in style and character suits its surroundings just as 'The Empress' appears fitted to Victoria. The architecture and interior of the Vancouver hotel suggest that it was built to please a committee of real-estate agents during a boom; it is pretentious in proportion, florid in decoration, and bustling in business; a swarm of Japanese 'boys' give it an Oriental touch; you find many more Americans, drummers, tourists, capitalists, and engineers, here than at Victoria. Two years ago Vancouver had a population of 125,000; since then the boom has collapsed, so that the population is about 100,000, but it remains a busy place, and a great port.

After a day of reconnaissance we took the train for that important smelting centre, Trail. The C. P. R. track crosses the peninsula from Burrard inlet, on the south shore of which Vancouver is situated, to the west bank of the Fraser river, which here flows nearly due south. A big, but turbulent, stream it is. Scenery on a big scale is everywhere to be enjoyed. For the most part, British Columbia is a mountain land richly forested, cleft by big rivers and jewelled with long lakes that follow lines of glacial erosion. Leaving Vancouver the railroad passes through clearings, bordering the river, on which fruit and grain are cultivated profitably. At Agassiz is a large experimental farm, which furnishes much practical information to the new settlers. In a country so sparsely populated it surprises one to see another railway grade on the opposite bank of the river. That is the Canadian Northern railway, built by those great hypnotizers Mackenzie & Mann, contractors, both of whom have now a prefix, for both have been knighted, the one being Sir William and the other Sir Donald. They floated bonds on the strength of the anticipated wheat haulage from the grain fields of Alberta and Saskatchewan to Vancouver. Incidentally it is to be remarked that the pioneers of exploration and of railway development in Canada were mostly Scots. The first transcontinental railway owed its origin mainly to the indomitable pluck and foreseeing initiative of Donald

A. Smith (Lord Strathcona) and George Stephen (Lord Mt. Stephen). The Fraser river was first explored by Simon Fraser, an officer of the North-West Fur Company, in 1806. He thought it was the Columbia, but later he followed it to the sea, and for this the river was named after him. In 1857 the finding of gold on the Fraser started the first big rush into British Columbia. In 1859 two parties from Eastern Canada came overland by way of the Yellow Head pass. The lower reaches of the Fraser are no longer important as placer diggings, but millions of dollars were won from Boston bar, a few miles below Yale, and when the water is low the patient Mongol is yet to be seen gleaning gold from the shelving sand. The Fraser yielded its richest treasure nearer its source, at Barkerville, in the Cariboo district. In the early days stern-wheel steamers plied as far up-stream as Yale and the road to the upper diggings crossed the Fraser at Spuzzam, going thence to Barkerville.

Night drew the curtains on the scenery. We awoke at Revelstoke, where passengers for the West Kootenay country take another train, which brings them, in 27½ miles, to the head of Arrow lakes, expansions of the Columbia river, a linked water-way on which they voyage for 130 miles in a stern-wheel steamer for the whole of a long day, arriving at Robson in the evening. This lake-travel is a marked feature of transport in British Columbia; it is pleasant and picturesque. The last time I had made the same journey was with a client, the late Ralph Baggaley, in 1901, when we had as fellow-passenger a solitary soldier returning from the Boer war. He had left his little ranch on the lake and gone 13,000 miles to fight for his country; he had done his duty, and returned to his log-house and its patch of cultivation, disembarking from the steamer on a lonely wharf, where no one came to greet him, no one gave him a hand. To me he seemed truly heroic, a noble citizen, a man who had done his duty quietly and thoroughly. This time, going southward from Arrowhead, we had 90 khaki-clad soldiers on their way from the camp at Vernon to their homes, during a brief holiday from training. They too had volunteered for service on a distant battlefield. A sturdy set of fellows they looked—vigorous and alert. In the morning paper I read a speech by the Premier of the Province, Mr. W. J. Bowser, in which he stated that one out of every 13 in the population—men, women, and children—of British Columbia had volunteered for service with the Allies in Europe. During the days spent in the Province I obtained plenty of evidence of the wonderful loyalty of the people to their home-land and to a cause they have truly at heart. Of the surveyors 107 out of 260 on the register have gone to the front, and of the remainder the majority are too old or physically unfit to go; at the Blue Bell mine, where 85 men are on the pay-roll, no less than 27 had gone to the front; at the Hedley mine, 41 out of 150 had volunteered; and returning from Howe Sound on a little steamer the captain told me that 23 out of 60 in the company's employ had enlisted. At every mine in British Columbia each employee, from manager

MAP OF SOUTHERN BRITISH COLUMBIA, SHOWING THE BOUNDARY REGION.

to roustabout, voluntarily contributes one day's pay or more per month to the Patriotic Fund, which is intended for the benefit of the dependents of the soldiers. Many of the technical men and superintendents are Americans, but they also 'chip in' with pleasure. Incidentally, I found many Americans that had become naturalized; it seems easier for an American to become a Canadian than to become a Britisher; but that is not surprising, for the Canadian idea readily fuses the American ideal with the British tradition.

At Trail we remained for three days, appreciating diverse metallurgical operations, while enjoying the hospitality, mental and physical, of Mr. and Mrs. E. H. Hamilton. Our host was another McGill graduate (class of '84). This Canadian university has produced a number of notable metallurgists: Mathewson, Carlyle, and Robertson have been mentioned. The Hamilton brothers constitute a noteworthy trio, E. H. at Trail, A. McL. at Aguascalientes, and W. J. at Cerro de Pasco. Later I shall go into the details of the electrolytic practice at Trail. This smelter was built originally to treat the output of Rossland, which still supplies 1000 tons out of the 1600 treated daily. The plant overlooks the Columbia river, which flows southward around the mountain constituting the Rossland mining district. Only six miles away, on the American side of the boundary line, is the Northport smelter, now operated by Harry L. Day of Spokane, the owner of the Hercules and other silver-lead mines in the Coeur d'Alene. The Trail smelter was built by that splendid adventurer, F. Augustus Heinze, but it is now controlled by a financial group identified with the C. P. R. A clever staff of technical men is in charge and good work is being done. It is the only metal refinery in Canada, and is playing a decisive part in the development of the Boundary region—a name given to that part of British Columbia adjacent to the international line, which is the latitude of 49° north.

Everybody goes to Nelson, the principal town in the Kootenay region. It was an important mining centre 15 years ago and continues to be the chief place of residence, being the terminus or division point of the C. P. R., Kettle Valley, and Great Northern railways. Situated on the mountain-side above the west arm of Lake Kootenay, it has a charming site and a lovely outlook. Here we were met by an old friend, S. S. Fowler (Columbia '84), who took us in a motor-launch to Riondel, 30 miles

distant, on the main lake. In this part of the world everybody uses the motor-launch, it is the gondola of the mountains. We arrived at dark, having enjoyed the long twilight of this northern latitude and watched the day fade behind the dark forest-clad mountains. Concerning the Blue Bell mine and mill, of which Mr. Fowler is manager, I shall have something to say in a later article. The mine is situated on a peninsula from the summit of which the traveler gains a fine view of the lake, up and down. Here the lake is 2½ miles wide; on the opposite side are the mountains that separate it from the Slocan lakes, which fill narrow valleys between off-shoots of the Selkirk range. Riondel looks across the lake to Ainsworth, where are several silver-lead mines. The picture is framed by the tall columns of the Douglas fir, a species characteristic of the Pacific slope of the Northwest. This noble tree is also known as the Oregon pine; it is the *pseudotsuga Douglasii* or false hemlock, both unpleasant names. But it is a handsome tree and adds greatly to the beauty of the British Columbian landscape.

Looking across the lake one can see the few houses that constitute the settlement of Ainsworth and the lines of clearing that indicate the course of various tramways from the mines on the mountain-side to the shore below. Dumps dot the forested slope. Southward, toward Balfour, are the scattered rock-piles of the Highlander group, now idle; behind them, but not visible, lie the United and other claims now being developed by A. W. McCune, of Salt Lake, who is driving a long adit to tap the expected continuation of a silver-lead orebody. North of Ainsworth, high on the mountain, is the No. 1 mine, belonging to the Consolidated Mining & Smelting Company and yielding a silver ore, poor in lead, for the smelter at Trail. Near-by is the Silver Hoard, owned by Spokane people. These two mines mark replacements in limestone, while the United is a fissure crossing the schist and limestone. The No. 1 has a tramway to the lake-shore. Farther north is the Highlander connected by tram with a concentrating mill at the water-side, where Cedar creek enters the lake. This also belongs to the Consolidated and yields a silver-lead ore. Beyond the Highlander, farther north, are the Florence and other properties controlled at Spokane. The Florence is building a concentrator in a clearing close to the shore. There is talk of a 300-ton plant, using flotation. The

Ainsworth district is said to be fairly prosperous and is likely to become more productive, the current development work being well planned. Reciting the various ownerships one is reminded of the large part played by Spokane operators in the exploitation of the Boundary and Kootenay mining districts. Most of these energetic Americans began their British Columbian experience at Rossland, where several of them made much money. Patsy Clark, John A. Finch, A. B. Campbell, Charles Sweeney, and John R. Cook were the leaders, for most of them have gone over the last range. Mr. Cook and Col. Payton continue the tradition. Such names as Yankee Girl, Mollie Gibson, New Denver, and Silverton suggest the number of miners from Colorado that helped to prospect the Kootenay districts. Indeed, the friendly co-operation between Canadians and Americans is a part of the history of British Columbian mining.

After a memorable glimpse of home life in this lovely wilderness, we returned in the motor-launch, 12 miles to Balfour, where we caught the steamer plying between Kootenay Landing and Nelson. The scenery is well remembered. Terraced lines along the mountainsides mark the escarpments or edges of bedded rocks. Variation of foliage is due largely to forest-fires of different periods. The mountains are clad in foliage to their very summits, save those that reach perpetual snow. The dark silhouette of the ranges provokes the imagination with questions of the beyond. Along the shore of the lake a white rim is made by high-water washing the rock, which is fringed with bleached drift-wood. Inlets are bordered with sandy beaches, but elsewhere the cliff plunges at a high angle into deep water. A great stillness broods over these long and narrow lakes; man's trespass is relatively inconsequent; the purring of a motor-boat or the pulsating splash of a steamer is heard at rare intervals, but the birds are few and the smoke of human industry does not stain the blue of a tranquil sky.

Between Nelson and Grand Forks one receives a reminder of British Columbia's great asset in water-power, for at Bonnington falls the Kootenay river leaps and runs in joyous strength. Enormous reserves of power for developing electric energy are plainly available. The traveler also hears about the Donkadors, the Russian peasants occupying farms along the big river that becomes the Columbia and along the Grand Forks valley, which is watered by the Kettle, another tributary of the Columbia. The Donkadors live under the patriarchal system, their chief being Peter Veregin, a man of unusual ability. About 8000 of these Russians have settled in British Columbia, on a suggestion made by the son of Henry George to the son of Leo Tolstoy. The Donkadors refused to serve in the Russian army, being opposed to the killing of any living thing, even fish. They are vegetarians, and at first would not employ horses for pulling the plough delegating that task to their women. Now they use horses, but the women and children constitute an important part of the field labor. They are hard workers and intense cultivators. From the train one can see the stereotyped dwellings of this community, two brick houses connected at the rear by a

longer dwelling, this being set aside for the unmarried while the wings in front are occupied by the married folk. At Robson the Donkadors have built a handsome concrete bridge and near-by is their jam factory, the products of which are highly extolled. While orderly, they refuse to keep vital statistics and will not permit their children to go to school. The Provincial Government has humored them, but not without a few quarrels with the local authorities. If employed off their farms they go in groups, not as individuals, and payment for their work is made to the patriarch. How desirable they are as an element in the population of the Province is a matter of dispute. To me they seemed a gain, for they are quiet, industrious, and productive. Some of them have broken away from the organization and have started farms on individual account. In course of time they will learn to speak English, they will see the advantages of sending their children to school, intermarriages will ensue, and a few decades hence the manner of their coming will be a tradition. Like the Boers and the Mormons they will be engulfed in the tide of life around them.

From Nelson we returned to the Coast over the Kettle Valley railroad, a line that runs near the boundary and serves as a chord to the arc made by the route from Vancouver to Nelson by way of Revelstoke and the Arrow lakes. The line as a whole had only just been opened to passenger traffic. It serves the Boundary region, passing through such mining centres as Grand Forks, Greenwood, and Princeton. Leaving Robson the railway runs along the precipitous mountain slope above the lower Arrow lake (or Columbia river) and then turns westward among the fir-woods overlooking Lake Christina. But the best scenery is east of Penticton, the town at the south end of Lake Okanagan. The railroad makes two great horse-shoe curves above the Kelowna valley. Kelowna means 'the bear,' the valley being named after an old settler whose grizzly beard caused the Indians to liken him to a denizen of the adjacent woods.

But it is of the view from the high-line railroad that I wish to speak. In the twilight we made the turn that unwound the panoramic film of wonderland. The foreground of rocks and firs descends into the vague vastness of a far-spreading valley, varied by patches of cultivation, dimly discernible in the fading light; it is a continental topography in miniature, little ranges of hills and scattered surfaces of water, beginning to reflect the afterglow; on the farther edge of this broad valley there is a series of linked lakes whose ruffled silver alternates with still water reflecting the dark slopes of the onlooking mountains—a big range of flat-topped summits, suggesting remnants of a great plateau, sharply silhouetted against a saffron sky. No sign of man appears save the level scar of the railroad grade cutting the forested slope, but a big black bird, like the spirit of evil, crosses the sunset and vanishes into the woods. Fainter grows the light. To the north the blue hills of Okanagan fade into the purple distance, the sound of a water-fall fulfills the sense, and the twilight merges into a starry night.

Soon the lights of Penticton appeared, the train ran

THE HARBOR OF VICTORIA AS SEEN FROM THE EMPRESS HOTEL.

YALE, B. C. THE FRASER RIVER AND THE CANADIAN PACIFIC RAILROAD.

down to the water-side, where the brilliantly illuminated lake-steamer was waiting to discharge and to receive passengers, while on the shore, behind an avenue of handsome trees, the lights of the Inco hotel welcomed the weary traveler. At Penttieton Mr. Gomer P. Jones, manager of the Nickel Plate mine, met us with his car, in which we motored to Hedley. The road was in excellent condition, for it had been swept clear of stones in honor of the Premier (Mr. W. J. Bowser) recently on a pre-election tour of the Province. At Olalla, 26 miles from Penttieton, we crossed the trail of a punctured boom. Ten years ago this locality boomed large in the daily press, the Sunday issues of the *World* and *Journal* in New York published full-page pictures of the supposed mines, also of an imaginary race-course, smelter, and town, as well as of trains running on an imaginary railroad, all of which, as Mr. James W. Gerard, now at Berlin, would say, "originated in the fertile imagination of the boosters." Yet there was some fire to this smoke, for the Dolphin, the prospect that gave some color to the boom, is now shipping copper ore to the smelter at Grand Forks and numerous promising showings of ore are said to exist. Near Keremeos, six miles south, is the Horn Silver, a new mining enterprise that is shipping high-grade silver ore, also to Grand Forks, where is the smelter of the Granby Consolidated company. From Keremeos it is 18 miles to Hedley, up the valley of the Similkameen. The first sign of industry is the flume and power-house; then the Striped mountain, so named by Dawson, introduces the characteristic geology of the district—a series of limestone beds intercalated by sheets of eruptive rock.

The mine is 3700 ft. above the mill. It was a hot day—August 26—when I made my visit to the upper workings. In the No. 3 adit the ice of winter lingered, the door of the "tunnel" being kept closed so that the ice might be conserved for use in the boarding-house. The temperature was 40° F. On the porch of the storehouse it was 80° and at the mill it was 95°. Descending by the tramway, the air became sensibly hotter and during the last thousand feet of descent it seemed like the approach to Tophet. Concerning the geology and ore deposits I shall write separately. From the upper terminal of the tramway, one obtains a fine view of the region, the Boundary country, as it is called, for the international line is only 30 miles south. Incidentally, it may be remarked that if the line had been drawn one degree farther north, that is, the parallel of 50°, it would have excluded several rich Canadian mining districts, while if it had been placed one degree southward the extension would have included little valuable mineral territory, save Republic and a few prospects in the Cascades. Where we stood, at the head of the tramway, our western horizon was bounded by the Hope mountains, on the near side of the Fraser river. South-west the white summit of Mt. Baker stood sentinel. At our feet the winding valley of the Similkameen river lost itself in the maze of the Cascade range, westward, for its source is in the United States, while the chief tributary, the Tulameen, which starts in the Hope mountains, joins it at

Princeton. This is a promising mining district and is attracting attention just now.

In order to catch the train at Princeton, we had to motor thither between midnight and 1:40 a.m. To kill time Mr. Jones took us to the moving-picture show. While there the electric lights flickered three times, this being a signal, so I was told, that something was wrong at the power-plant. None of us guessed the cause of it, but when we emerged from the 'movie' hall, the sky was glorified with the *aurora borealis* or northern lights. The spectral streamers thrown to the zenith looked like ribbons of luminous gas issuing from a furnace beyond the dark rim of the northern mountains. The last time I had seen a good display of this magnetic phenomenon was at Rat Portage (now Kenora) in Manitoba in June 1897; while farther north, in the Yukon and Alaska, I was not so fortunate. The idea used to prevail that the aurora was caused by electrical discharges in a frosty atmosphere, that is, one containing multitudinous particles of ice, but recent scientific observation gives another and more satisfactory theory: "that electrified particles, shot out from the sun with great velocity, are drawn to the earth's magnetic poles along the lines of force. Striking the rarified gases of the upper atmosphere, they illuminate them, just as the electric discharge lights up a vacuum-tube."* The lowest height above the earth's surface at which the aurora has been observed is 25 miles, at which level the electrons from the sun would penetrate a nitrogen atmosphere, while at a height of 60 miles the atmosphere consists largely of rarified hydrogen. When sun-spots are numerous, the discharge of electrons is most violent and the most brilliant auroras are observed, but the night-sky is always illuminated in some degree owing to the penetration of the earth's atmosphere by these solar emanations. On the evening mentioned—August 26—the electricians were perplexed by the irregular behavior of their apparatus and we learned next day that telegraphic communication was interrupted for a period of 20 minutes while the earth was being bombarded by solar ions.

Leaving Vancouver at 9:15 a.m. on August 28 by the S. S. *Bellona*, I arrived at Britannia Beach at 12:30. The distance is only 28 miles, but the steamer makes several calls, two of them at different points on Bowen island, a holiday resort, where camping parties depend upon this vessel for mail and supplies. Bowen island is 14 miles from Vancouver, at the entrance to Howe sound, near the head of which is Britannia Beach.

The forest fires near Bellingham, in Washington, had blown smoke across the international boundary so as to make a murky atmosphere, through which the Cascade range loomed with magnified impressiveness. Emerging from Burrard inlet, on which Vancouver stands, and going around the Point Atkinson promontory into Howe sound, the traveler sees a railroad grade on which no trains are running. This extends from North Vancouver

*Birkeland's and Störmer's theory as stated by Ira Remsen before the National Academy of Sciences, at Washington, on April 22, 1913.

FARMS IN THE ENVIRONS OF VICTORIA, B. C.

THE QUARRY-GARDEN OF THE CEMENT WORKS, VICTORIA.

to Horeshoe bay, 9 miles, and will connect eventually with the Pacific Great Eastern railroad now running 120 miles from Squamish, at the head of Howe sound, to Lillooet, and 47 miles farther to railhead at Clinton, traversing a mining region of some promise, notably around Pemberton. The line is planned to reach Prince George, on the Grand Trunk Pacific. This part of British Columbia is the scene of railroad schemes that anticipate a traffic of continental proportions; indeed, much of this activity is founded on the expectation that the grain trade of the prairie provinces east of the Rocky mountains must find an outlet westward.

Entering Howe sound, the bluster outside gives place to quiet water and a summer air. Near Anvil island the scenery becomes Norwegian in its boldness. Snow-capped peaks overlook the inlet and steep forested slopes enclose it. As the little vessel ploughs her way through waters in which high mountains are reflected there comes that recurrent feeling that we are adventurers entering the unknown, voyagers with Vancouver or Wrangel into a new world. Headland after headland projects forward in fine perspective. The steamer turns a point, runs into a pretty bay, enclosed by cliffs above which the forest rises, tier on tier, up to the snow. This is Porteau, where a plant for exploiting the gravel and rock used by contractors in Vancouver is situated. Five miles more and the houses on the beach at Britannia emerge from the haze, along a wide bay indenting the eastern shore at a point six miles from the head of the sound. First the red roof of the old vamper-building appears, then the green roof of the big department-store, and finally the terraced building of the new mill and the reddish cutting of the tramway, with the ordered array of houses constituting the settlement tributary to this important copper mine. Concerning the mine and mill, I shall have a good deal to say in another and more technical article. I spent a couple of deeply interesting days at Britannia, returning late in the evening of August 29. By courtesy of an introduction to the captain, I was permitted to sit in the pilot-house, a position from which the charm of the scenery was intensified by detachment from the other passengers. It was interesting to watch the navigation. The flare of the Atkinson light was seen on the clouds long before the direct rays were visible and I noticed that when within the glare from the lighthouse it was extremely difficult to distinguish the lights of other vessels. The rule of the road at sea is to keep to the right. When approaching another vessel it is the custom to turn to starboard (right) and show your port (left) light, which is red. The Narrows, at the entry to Vancouver harbor, is being dredged, so that there is little room to spare. The bewildering effect of the many lights, fixed or moving, and the difficulty of distinguishing those that were meant to guide the navigator, gave me some idea of the alertness required in the pilot house. Undoubtedly the short voyage from Vancouver to Britannia is one of the most pleasant the technical traveler can make; the courtesy of Mr. J. W. D. Moodie and his staff made it memorable among my many journeys of observation.

Returning to Victoria, on the way home, we allowed ourselves a couple of days of rest. Meanwhile I went to the office of the Provincial Mineralogist for further information concerning some of the districts visited. Then, by courtesy of Mr. and Mrs. Robertson, we were shown some of the environs, including the cement works and gardens of Mr. R. P. Butchart, on Tod inlet. The manufacture of cement was highly profitable a few years ago, notably during 1910 and 1911, when railroad construction was active on the mainland and the building boom was at its height. In this locality, 12 miles north of Victoria, the limestone lies under clay and adjacent to tidal water. The plant has a capacity of 3000 barrels per day, the 'semi-wet' process being employed. After the limestone has been crushed it is mixed with clay in the proper proportions and 31% of water to the consistence of a rich cream. This mixture is then roasted in a 'kiln' with finely ground coal made from the screening known as 'washed pea' and 'washed slack,' the consumption of coal being in the proportion of 50 tons per 1000 barrels (a barrel weighing 350 pounds). The kiln is a rotating iron cylinder 170 ft. long, tapering in diameter from 10 to 9 ft. Three other kilns are smaller, from 125 to 150 ft. long, and with a minimum diameter of 7½ ft. From this the 'clinker' emerges in particles up to 1 inch in size, to which 3½% gypsum is added as a 'retarder,' that is, to prevent the cement from setting too quickly. Thence after passing through a cooler the new mixture goes to Sturtevant ring-rolls, by which it is pulverized, in two stages, to 20-mesh and then re-ground in 10 tube-mills (in several sizes, 6 by 22, 5 by 22, and 6 by 18 ft.) to a dust 88% of which will pass a 200-mesh sieve. In the tube-mills 4, 5, and 6-inch chrome-steel balls are used for preliminary reduction, then flint pebbles, then steel slugs. The sacking of the cement is done by tying the neck of the bag, but leaving a hole at one of the bottom corners with a flap inside so that it closes automatically when the bag is filled. This is called the Bates valve-bag.

So much for arid technology. This manufacture of cement furnishes a financial and physical background for a lovely pleasure. Walking with an eye on the chimneys of the cement works, the visitor passes through a cleft in the rock and suddenly finds himself looking down upon a sunken garden, the conversion of an abandoned quarry, the bottom of which has been leveled into velvet lawns while the loose stones have been piled into rockeries over which flowering plants are climbing in glad profusion. Wild duck—their wings clipped—swim on a little lake. Water runs amid the parterres and a waterfall adds sound to color. The masses of bloom gladden the rocky ramparts of the quarry and deepen the mystery of the untutored wilderness in the background.

Let that be the closing chord. In large measure it typifies British Columbia: the homes, the fields, and the gardens nestling amid the rugged mountains, the primal forests, and the wide waterways of a land rich in natural resources and richer still in a people that has responded to the call of an old tie and the impulse of a great devotion.

Potash-Bearing Minerals of California

By Herbert Lang

INTRODUCTION. The extreme scarcity and enormous rise in price of potash compounds incident upon the War and the shutting off of German importations have made the development of a domestic supply imperative. Every State in the Union possesses potential potash, either in the form of organic or inorganic reserves, but in no case can an adequate supply be obtained immediately, and a prolonged struggle will be required to overcome the evils of a situation brought about by the preceding years of free-trade in chemicals.

It goes almost without saying that California, so rich in varied mineral resources, possesses ample supplies of potash and in varied forms. Among vegetal substances her seaweeds are pre-eminent in their potash contents. In the Searles lake-bed she possesses perhaps the most extensive deposit of the kind on this continent. In her widely scattered feldspar formations she appears to have an inexhaustible reserve, which, when suitable methods of extraction are developed may displace all other sources of supply.

It was natural that when the dearth of potash was realized fully that men should turn with feverish energy to the task of utilizing the material most immediately available, and to which the simplest methods of extraction are applicable. Such are the dry lake-bed salts, and the ash of the kelp, from both of which the potash salts may be dissolved by water. The easy solubility of the chloride, the sulphate, and the carbonate of potash favors extraction and purification, but it so happens that corresponding salts of sodium, of equal or greater solubility, accompany the potash contained both in the lake-beds and in the seaweed, so that some embarrassment is felt and some inconvenience occasioned by their presence. The desert salts of the dry lakes contain, especially at Searles lake, at least four sodium compounds that inter-crystallize with the potash, which exists mainly as chloride, and prevent its easy separation. These are sodium chloride (common salt), the sulphate, the carbonate, and the borate—all valuable chemicals in their place, but not so valuable when in the wrong place. If it becomes necessary to transport, crystallize out, and throw away a ton of common salt and half a ton of sulphate of soda in order to obtain a hundred-weight of salable chloride of potassium, the operation may not prove lucrative.

A large number of native rocks contain potash, but those rich enough for making potash are not above three or four in number. At the head of these stands orthoclase—potash feldspar—a usual constituent of granite and gneiss, which are well distributed in many parts of the State. Granite and gneiss of themselves would not serve to make potash, but pegmatite, a related rock, in which the three constituents, mica, feldspar, and quartz

are segregated into comparatively coarse particles, is the usual source of feldspar, which is separated from the other two by cobbing. The mica, should it prove to be muscovite, the light-colored species, also contains potash and except for its slightly greater content of iron, is equally promising as a source of potash. Both are natural silicate minerals, composed chiefly of silica, alumina, and potash, along with various subordinate impurities, chiefly soda, lime, magnesia, and iron. Although the theoretical composition of orthoclase shows a content of 16% and above of potash, I have not found by actual analysis a greater proportion than 14.2% in the course of fifty or more determinations, on California feldspar. I think that the average cannot be far from the percentage stated above, namely 10%. The alumina runs invariably from 18 to 19%, the silica keeping close to 65%.

The average potash content of muscovite is about 10%, thus sensibly equaling orthoclase in this regard. It is less abundant, but perhaps more widely distributed. Viewed as a source of potash, mica would possess an advantage over orthoclase as containing less silica, but it contains more magnesia, which would prove objectionable as interfering with crystallization.

POTASH FELDSPAR is known to exist in many localities in California, several of which are easily accessible, lying upon or near important transportation lines. One of the best known of these deposits is near Chualar, in Monterey county, from which several shipments to the potteries have been made. The crude (unground) rock from this source commands about \$7 per short ton laid down in San Francisco. It is said a considerable exposure of good rock occurs there. Extensive deposits are reported from Kern county, but at some distance from the railroad. The best-appearing feldspar as yet offered on the market is that of the King quarry, in Inyo county, where large quantities are said to exist. This rock is remarkably white, clean and well crystallized, and should prove well adapted to the making of potash. It can be had at about the same price as above-mentioned. Probably twenty or more localities have been reported at one time or another, here and there throughout the State; so there seems to be no dearth of feldspar, at least.

Assuming a price of \$7 per ton at the factory, and an average content of 10%, or 200 lb. per ton, it appears that the raw material for one pound of K_2O would cost $3\frac{1}{2}$ cents. While K_2O is not a salable product, of course, KHO , the hydrate, called usually caustic potash, is sold in large quantities, commanding a price at ordinary times of 6 to 7c. per lb., but selling now for about 80c. Most potash salts are selling now for from ten to thirteen times their normal price. The native chloride from Stassfurt, that brought \$32 per ton before the War,

commands now \$425 per ton, and the sulphate is almost as dear. These, he it remarked, are impure commercial salts, containing from 10 to 20% impurities. Refined potash compounds are not quoted now in cents per pound—the quotations are in dollars. Nine-tenths of the potash came from Germany, and under the stimulus of free trade we paid the Teutons far more than a hundred million dollars for it in ten years, getting it so cheaply that all domestic supplies were cut off. But the loss and inconvenience arising from the interruption of imports during the past two years has more than offset the gain previously made, and we have neither potash nor a potash industry. I venture to say that if we had had a protective tariff stiff enough to have kept the German product out we could have saved the \$100,000,000 and built up an industry that would have protected us from the consequences of foreign wars. It is a great object-lesson in political economy.

ALUNITE. Next comes the mineral alunite, which is found in the arid parts of the West, and is undergoing exploitation for the same purpose. Alunite is a sulphate of potash and alumina, the former becoming soluble in water after heating. Here we find a decided difference, because neither mica nor feldspar are affected in the least by water, nor will they yield to even the strong acids. Since special measures are not necessary for rendering the valuable base soluble in case of alunite, this mineral becomes more immediately available for potash production than the silicates, and is leading them in exploitation. However, it seems to occur only in comparatively inaccessible situations, whence transportation becomes a ruling factor. We have to consider also the important fact that no useful by-products can be expected from alunite, whereas feldspar is capable of yielding two at least of these—precipitated silica and alumina sulphate, which may go far toward reimbursing the total cost of reduction. Such considerations must be had if we would found the manufacture on an enduring basis.

The deposits of alunite thus far reported do not seem to contain potash to so high an extent as ordinary orthoclase; in fact, they do not appear to average over 6 or 7%. But as the mode of extraction does not contemplate the decomposition of the whole mass, the remaining matters may be disregarded.

LEUCITE rock, another source of potash, is a complex lava, in which the potash exists in no less than three distinct silicate minerals, namely, leucite, feldspar, and phlogopite or magnesia mica. The leucite and the mica are soluble in sulphuric acid, but the feldspar is not; and acid treatment only avails to extract perhaps two-thirds of the total potash. Added to this, the accessory matters, of which the rock contains a great many, complicate the processes of separation. Chemists have found some 20 constituents, of which over a dozen are basic, there being iron in two forms, magnesia, and other troublesome matters, which makes the problem of separation one of great complexity. The average potash contents, as shown by the few analyses at hand, does not

exceed 10 or 11%, which puts leucite rock into the class with potash feldspar and potash mica. Perhaps the most serious objection to this rock, called occasionally *wyomingite*, is that it is found only in Wyoming, whence the transport of its products would be subjected to heavy charges.

ANALYSIS OF POTASH MINERALS. In this journal of August 5, 1916, W. B. Hicks describes some useful field-tests for potash in the common minerals, to be performed with a minimum of apparatus. Should the investigator be possessed of more facilities and skill, he may continue his researches farther. The estimation of the alkalis in complex minerals has always been held to be beyond the resources of ordinary chemical manipulators, but it has become a necessity to make the determinations rapidly and accurately. I shall describe my method, in which there is nothing especially new. As a rule it is not requisite to determine anything except the alkalis, nor would we desire to estimate the soda were it possible to escape doing so; but the determination of one alkali involves that of the other. As there is no proper precipitant for potash or soda, we are compelled to remove all the other bases from the solution before it becomes feasible to isolate and weigh the alkalis. I weigh out a gram of the finely powdered mineral, having first dried it at the boiling-point of water to eliminate moisture. I wish to emphasize the matter of pulverizing, since the success of such operations depends upon getting the substance into the finest possible condition at first. I mix the substance with about 5 cc. strong hydrofluoric acid (about 35%) in a lead dish of good size, and place on the water-bath. After the violence of the reaction has ceased, I add successive small amounts of hydrochloric acid and evaporate to dryness, when the residue, consisting of chlorides of the various bases, along with a small amount of gelatinous silica resulting from the decomposition of the silicon fluoride by the water brought in by the acid, will be found as a loose powder, provided that sufficient acid was used. The dried powder I then transfer to a porcelain crucible and heat to low redness, for the purpose of expelling as much as possible of the aluminum chloride which would otherwise afford a bulky and annoying precipitate at a later stage. The addition of a few drops of nitric acid during the evaporation has served to oxidize all the iron present to the ferric form, ferric chloride being somewhat volatile also. After taking up with water and boiling, the various remaining chlorides are dissolved, when, without stopping to filter the silica, etc., I immediately precipitate the iron, lime, alumina, and all other bases with a mixture of ammonium hydroxide and carbonate, added in excess, boil and filter, thus getting rid of everything except a part of the magnesia, which is somewhat soluble in ammoniacal compounds.

Evaporating the filtrate to dryness, igniting the residue to drive off all the ammoniacal compounds, and again dissolving and filtering, gives a solution containing the chlorides of the alkalis in a state of purity. It is often necessary to repeat the evaporation with the

addition of a little ammonium carbonate to get rid of final traces of magnesia. The chlorides are dried, ignited, and weighed together. From this point the processes diverge somewhat. We may precipitate potash next as chloro-platinate in the usual manner, but this involves the use of a weighed filter, since the salt decomposes on ignition and at a temperature as low as 150° C. Or, we may estimate the chlorine in the residue by precipitation with silver nitrate, calculating back to the combined weight; but this method, while rapid and easy, is indirect, and few operators feel like relying upon it. Reduction of the chloro-platinate by means of oxalic acid is recommended by some; but I have done the best by cupelling the burnt filter with the chloro-platinate with silver-free lead, and weighing the residue of metallic platinum. If the operator has an assay-furnace at command, I should say that this is the best and most accurate proceeding, and certainly not difficult. Experienced chemists will understand why the customary method of decomposing the silicates by fusion with alkaline carbonates are inapplicable here, and why hydrochloric is chosen instead of sulphuric in the preliminary decomposition. The object is, of course, to find a short method for determining the potash alone, although the discovery of the amount of sodium present is useful.

Treatment of Molybdenite

At Renfrew, Ontario, the International Molybdenum Co. recently started a new treatment plant of 50-ton capacity in 12 hours. From ore containing as low as under 1% molybdenum a 70 to 80% concentrate is obtained. Grinding is not done below 60-mesh. A gyratory-crusher and rolls are used for this. The crushed ore is fed dry to a drum revolving in water at the head of the flotation machine. A large quantity of the sulphides, including most of the molybdenite, is floated. The stream passes down a gently-inclined box 12 ft. long. The iron sulphides are carried along with the molybdenite until they strike baffle-boards, which help to sink them. The baffles are vertically placed boards, over the edge of which the water carries the molybdenite. They interfere little with this mineral, but cause sinking of the other minerals. At Orillia a refinery makes molybdic acid, ammonium molybdate, and ferro-molybdenum.

Near San Diego, California, a 50-ton flotation plant was recently started by Shinn & Shinn of Sacramento to treat a low-grade deposit of molybdenite. At present prices, \$1.50 to \$1.75 per lb. of 90% product, a good profit is made on 1% or under, ore.

BAUXITE, the oxide of alumina, occurs in considerable quantities in British Guiana, in South America, and Americans have secured leases on some of the deposits.

A NATURAL-DRAFT COOLING-TOWER, with a capacity of 7300 gal. per minute cooled from 115 to 85°, was recently erected at a steel plant at Anderson, Indiana.

Mark Twain as a Metallurgist

By G. H. Clevenger

Mark Twain had a brief but highly illuminating experience in metallurgy, to which he devotes some space in 'Roughing It.' After having ascertained how long and dismal a job it was to burrow into the bowels of the earth and get the coveted ore, he learned that this was but half the work, and that to get the silver and gold out of the ore was the other half of a dreary and laborious task. In the course of a vivid description of a pan-amalgamation mill of the period, he observes: "One would not suppose that atoms of gold and silver would float on top of six inches of water, but they did."

Mark stayed in the mill only one week, when he told his employer that, while thoroughly infatuated with the business, he felt constrained to ask for an increase in salary. Whereupon the superintendent replied that he was paying him \$10 per week, and that he thought it a good round sum: "How much did he want?" Mark replied that he wished \$400,000 per month and board, which was about all he could reasonably ask, considering the hard times. Needless to say, he was ordered off the premises, but later, when reflecting upon those days and the exceeding hardness of the labor, his only regret was that he had not asked for \$700,000.

All that would have been necessary to put flotation in operation in the early Comstock mills would have been to go to the adjoining hills, gather the sage-brush abundantly growing there, subject it to destructive distillation, and add the tar-oil thus produced to the rapidly revolving pans, which would have made splendid agitators. The chemicals generally used—mercury, bluestone (copper sulphate), and salt could, of course, have been omitted. True enough, as recorded by Dan De Quille, friend of Mark Twain and co-editor with him on the Virginia City *Enterprise*, in his humorous volume entitled 'The Big Bonanza,' pseudo-investigators had gone to the 'hills' and gathered the sage-brush, and from it steeped a tea, which had been added to the pans, but this had not proved efficacious, for not only the essential oil contained in the sage was present, but also the extract of the tannin, which is now known to be deadly to flotation.

Had Mark Twain but realized that the floating atoms of gold and silver that he and others so persistently tried to make sink were but the manifestation of a phenomenon that was later to revolutionize metallurgy, he might have remained a mill-man for the paltry \$10 per week. But if the world might have had another famous metallurgist, we would not have had Mark Twain; and after all, who would trade a Mark Twain for a prosaic metallurgist?

AIR-PRESSURE tanks carrying over 25 lb. per sq. in. are to be inspected biennially by the California Industrial Accident Commission. There was one fatal accident in 1915, 6 permanent and 343 temporary injuries.

Measuring With the Steel Tape in Mine-Surveying

By Walter Scott Weeks

In a previous article* I developed a graphic method for correcting in one operation a measurement by a steel tape, for sag stretch, temperature, and initial error in the tape. It is the purpose of this paper to present a few suggestions for increasing the accuracy of the field-work.

In mine-surveying the vertical angles are measured from the head of the instrument to some definite point

FIG. 1.

on the plumb-bob string—a bit of wax, a match, or a target. The target I use is a small brass cross that can be moved up and down the string and clamped in any position. The construction is shown in Fig. 1. At the lower end of the cross may be seen a hook. This hook, with a small ring on the string near the bob, forms a means for rapidly shortening the plumb-bob string when the station is in the back.

On the end of the plumb-bob string is a hook for attaching it to a spad.

If the station is in the floor the cross is moved down so that the distance from the end of the bob to the cross is the desired height of point.

If the station is in the back, the cross is moved up until the distance from the centre of the spad to the cross is the desired height. The ring on the plumb-bob string is then slipped over the hook on the cross and the plumb-bob string is thus shortened in a moment. The portion of the string above the cross has no loose ends to confuse in the sighting for horizontal angles. Fig. 2

FIG. 2.

*M. & S. P., October 28, 1916.

shows the plumb-bob hanging from a back-station.

Owing to the fact that it is necessary for the head chain-man to hold the tape at any point along its length, some sort of a grip is desirable. For holding the tape I

FIG. 3.

devised the grip shown in Fig. 3. It operates on the principle of the eccentric. It is cast in aluminum, and will grip a tape of any thickness or width.

If the station is in the back it is necessary only to

FIG. 4.

grip the tape and hold the proper foot-mark at the cross.

If the station is in the floor, the aid of this particular grip becomes more apparent.

With a station in the floor, the surveyor must keep the point of the bob touching the tack, and he must hold the

proper foot-mark of the tape at the cross. This is easily accomplished by the use of the grip. The cross is slipped into the bracket provided for it on the front end of the grip. See Fig. 4. The tape is placed in the grip with the proper foot-mark directly over the cross. The chain-man can now give his whole attention to keeping the point of the bob over and touching the station-point. See Fig. 5.

The tenths and hundredths are read at the instrument. Tapes can be obtained with an extra foot on the zero end graduated backward from the zero point. With

FIG. 5.

such a tape the tenths and hundredths are read directly and, added to the reading at the cross, give the measured distance. There should not be over two inches of blank tape at the end, because a longer strip throws the handle too far back for the operator to hold and read at the same time. Fig. 6 shows a tape of this description.

In order that the tape-correction chart¹ may be used it is necessary that the 'working-pull,' which is 2000 times the weight of one foot of tape, shall be exerted.

The spring-balance best adapted to this work is balance No. 633 of the Chatillon Co. It has a range of from 0 to 30 lb. This can be obtained from any instrument company. I have replaced the ring on the end by a bar and placed an adjustable stop so that the working-pull

¹'A Graphic Method for Correcting Steel Tapes.' M. & S. P., October 28, 1916.

FIG. 6.

may be exerted without looking at the balance. Fig. 6 illustrates the device. The stop is merely a collar that slips over the balance. It is held in place by a set-screw. See Fig. 7. The pin opposite the set-screw fits into the slot in the balance. This pin holds the slot open when the set-screw is tightened.

A weight equal to the working-pull should be hung on the balance and the stop put in place without regard to the numbering on the balance.

Of course, the character of the survey must determine the degree of accuracy to be sought, but in any event the engineer ought to know what degree of accuracy he is approaching. The spring-balance arranged as in Fig. 6 is just as convenient as an ordinary handle. If the

working-pull is exerted the engineer may be sure that the combined errors due to sag and stretch will not be greater than 1 part in 4000. This statement is true for a steel tape measuring 200 ft. or less and holds for all angles of inclination. If greater accuracy than this is desired the temperature must be noted and the corrections taken from the chart.

FIG. 7.

W. W. Johnstone, of the Bausch & Lomb Optical Co., 154 Sutter St., San Francisco, has consented to make a few grips and crosses, so that if my suggestions should appeal to anybody he may obtain these devices.

My thanks are due S. J. Ogilvie and E. W. D'Evelyn, students in the University of California, for the photographs.

THE METRIC SYSTEM of weights and measures was in September made law at Lima, Peru. There has been a "lame metric system" in the republic for some years, but now the law must be followed.

THE TOTAL VALUE of the mineral production of British Columbia up to the end of 1915 was \$516,270,253.

OIL PRODUCTION of Japan during 1915 totaled 3,015,327 bbl., an increase of 272,807 bbl. over that in 1914.

Dredging in Australia

During 1915 there were operated in Victoria, Australia, 42 dredges, 17 pump-hydraulic plants, and 9 jet elevators. The dredges dug a total of 9,727,975 cu. yd. of gravel, yielding an average of 6.4 cents per yard. The average depth worked was 18.7 ft., the deepest being 39 ft. There were 566 men employed. Dividends totaled \$120,000 from 15 companies. The buckets varied in capacity from 3 to 8 cu. ft.,

and discharged from 10 to 20 times per minute. These companies are only capitalized at from \$7500 to \$140,000, excluding the Briseis, which is a subsidiary of a large concern operating in Tasmania. Its four boats treated over 1,250,000 yards, for 5600 oz. The initial cost of Victorian dredges is low, being only \$60,000 for the largest, others being \$17,000 to \$35,000.

The jet elevators moved 152,172 cu. yd., yielding 14.4 cents per yard. They employed 43 men. The initial cost of plant is under \$5000, most of them being \$500 to \$2000. As the operations are private no profits were reported.

The pump-hydraulic sluice system moved 1,849,967 cu. yd., yielding 14.8 cents per yard. Cocks' Pioneer, the largest, declared a dividend of \$24,000.

Over 80 tons of black tin was recovered from these operations. From 1900 to 1915, inclusive, placer mining in the State has yielded 8.4 cents per yard from 231,640,195 cu. yd. treated. In 1915 the total gold won was just under 50,000 oz., and dividends amounted to \$145,000.

The Sludge Abatement Board regulates mining in Victoria with the object of preventing impure water, sludge, or mining debris from causing injury to water-courses or farming land. The volume of suspended solids, etc., carried by streams, also chemical analyses of mine waters are given in the Board's annual reports; also notes on restraining mill and dredge tailing.

INDICATIONS of petroleum were noted in South America as far back as 1788, when Humboldt described the oil seepages and mud volcanoes of northern Colombia, but little was done toward oil development until 1896 when active operations began in Peru. Even at the present time commercial production is confined to Peru and Argentina and the combined yield of the two countries in 1914 was only 2,500,000 bbl., or 0.6% of the world's production. Practically all the countries of South America afford oil indications of more or less importance, but principal attention is now being given to Colombia, Venezuela, Peru, and Argentina.

Mining in the Jerome District, Arizona

By Charles F. Willis

The Jerome district has been foremost in the progress of Arizona during the past month. Old mines have revealed new orebodies; new mines have found orebodies; and new organizations have been formed with great success. The Verde or Jerome district for many years has been a wonderful producer of wealth. The rich deposits of copper ore have made local shares exceptionally popular with the investing and speculating public. The United Verde Copper Co., with dividends aggregating upwards of \$38,000,000, is well known in the mining world. Fortunes were spent by other companies in the Verde district in an effort to open other fine orebodies, and it was through the persistent work of the United Verde Extension Co. that the secret of Jerome's rich bodies of copper ore was solved.

A few years ago Extension shares were quoted in cents, now they are selling at dollars each, over \$40. Its rise has been a great surprise, especially on the Stock Exchanges. The Jerome copper belt is benefiting therefrom, and issues of shares by new companies are eagerly snapped up.

It has been announced that steam-shovel operations are to be commenced at the United Verde within the next six months, as a means of increasing its ore supply. The low-grade surface ore around the old smelter at Jerome is to be so excavated and transported to the Clarkdale smelter for treatment. There are hundreds of thousands of tons of this ore, particularly in the hill just north-west of the site of the old plant. It is proposed to steam-shovel right down to the fire that has been burning for 14 years in the Hampton stope. The fire can then be extinguished from above, thus ending a famous mine fire. Only preliminary work is now being done preparatory to starting a large shovel digging surface ores. At the request of the United Verde management, Louis S. Cates, manager of the Ray Consolidated, paid a visit to Jerome last week and looked over the ground that is to be moved by this method. Mr. Cates is an authority on steam-shovel operations, having had much experience in Utah and other States. The resignation of Will L. Clark, manager of the United Verde Copper Co. since 1904, is generally regretted here. His work has been excellent, and he uplifted the tone of the district.

The United Verde Extension has declared No. 2 dividend, of 50c. per share. A large surplus is being accumulated for future needs. The monthly output from 8000 tons of ore is around 3,000,000 lb. of copper.

The Green Monster has been another attractive company. Shares were over-subscribed six times before put on the market. From this mine it is reported that an orebody has been cut averaging 17% copper. The company has taken over the Copper Chief group, which adds greatly to its value, as the latter is already a producer having shipped ore for several months.

The Dundee Arizona is attracting considerable attention, its shares having almost doubled in market value within the past two weeks. Co-operative mining has been started in the district, and recently a deal was consummated with the Extension for a joint adit that will develop both properties. The large shoot in the Extension has been found to be on the same fault, about 1000 ft. north-west of the Dundee. The new machinery for Dundee is at the mine, and includes a 60-hp. hoist, a 12 by 10-in. compressor, and a 3600-gal. Cameron sinking-pump.

The Verde Apex and the Venture Hill have completed a joint development scheme on an equal expense basis, with a view to opening each at depth and exploiting the orebody recently encountered in the Venture Hill adit. The Venture Hill has proved the presence of high-grade ore, having found native copper in the schist. The drift in which the metal was found is now in 520 feet.

Another company that is exciting much favorable comment is the Calumet & Jerome. This company has recently installed a 285-hp. Diesel engine, generator, exciter, 112-hp. hoist, and a compressor with a capacity of 513 cu. ft. per minute.

Verde Hercules has let a contract for diamond-drilling to N. Bertrand of Bisbee. This is not the first attempt at diamond-drilling as a method of prospecting in the Jerome district. It is said here that a Los Angeles company had a drill operating on the Harryhausen property some eight years ago, and cut a rich orebody at a depth of 1000 ft. The story is that at that time the company became involved in legal difficulties, due to speculation in Oklahoma oilfields, so the drill-hole that opened the ore was covered up. This story is believed by the old-timers of Jerome. The Verde Hercules is very favorably situated, being only a mile from Jerome and on the U. V. & P. railroad.

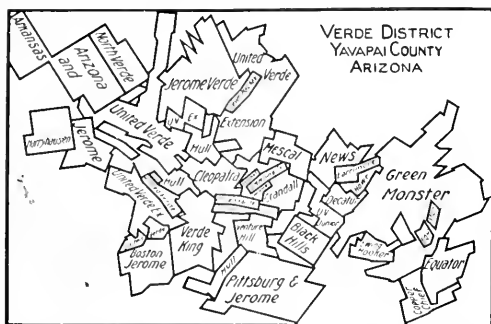

The settlement of the legal entanglements of the Hull Copper Co. has been one of the most important developments in the district, for the company has a mine of value. The new directors were selected at the annual meeting of the shareholders recently held, and include Will L. Clark, formerly manager of the United Verde, R. D. Tally, present manager, and Thos. Taylor, smelter superintendent for the same company. The Clark interests purchased a controlling share in the company a short time ago.

Jerome Superior is another one that borders on the United Verde, Verde Extension, Arkansas & Arizona, Jerome Daisy, Jerome Victor, and Verde Hercules. This property was recently sold to George Mitchell of Los Angeles for \$185,000.

Dave Morgan, superintendent of the United Verde Extension, has been appointed by the Verde Combination as its general manager. It is reported that George Kingdon, general manager of the Greene Cananea, will take charge of the Extension. The Verde Combination is well financed for an extensive campaign of development, having \$400,000 and 500,000 shares in the treasury.

The Arkansas & Arizona is a hive of activity. Recently L. D. Ricketts, John C. Greenway, general manager of the Calumet & Arizona, Ira Joralemon, and Philip D. Wilson, geologists for the Calumet & Arizona, and Will C. McKee, chief mechanical engineer for the same company, visited the A & A property. Although the object of their visit is unknown, there has been more activity at the A & A since that time, the force having been materially increased. This is one of the older mines of the district, having been worked extensively some years ago.

The Jerome Daisy Copper Co., which has been in existence only two weeks, was a sensational promotion. In nine days from the time of offering the reorganization stock, the secretary, A. J. Kisselburg, was returning

checks, drafts, and money orders, owing to over-subscription. Practically all of the shares were sold within Arizona.

The United Verde Consolidated has been another successful and rapid promotion. This company proposes to explore by diamond-drilling, and is about to let a contract for 20,000 ft. of work, with two drills.

A new promotion a day has been almost the rule for the Verde district, and local business men have organized to stop wild-eating before it starts. The idea is to use some sort of censorship over new mining schemes, and news of the district, to prevent, if possible, the public from being fleeced by promoters who are attracted merely by the prosperity of the district, and the ease with which Verde stocks are selling. While nothing will be done to discourage legitimate mining, everything possible will be done by this civic league to prevent wild-eats. A committee was appointed to formulate a working plan, consisting of Will L. Clark, Dave Morgan, and W. S. Humbert, managing director of the Green Monster, acting for the mining interests, and R. J. Stevenson, J. C. Scott, and Charles Du Bois acting for the business men.

Judging by the full-page advertisements in Arizona papers, urging people to buy shares in Jerome and other districts' new mines, promoters are exceptionally busy.

Jerome is full of activity, practically all of the companies operating having sufficient money in their treasuries to insure complete development. For many years this was thought to be a one-mine centre, but it is no longer considered in that light.

Mining in Cuba*

The prevailing high price of the base metals has given a great impetus to the mining industry of Cuba. In consequence, a large number of concessions has been granted by the Government; many of the old mines have been re-opened and much development work has been done; prospectors have uncovered numerous veins, some of which give promise of becoming productive mines.

Particular attention has been directed to the province of Pinar del Rio, in the extreme western part of the island. In 1915, no less than 95 concessions, to mine in this province, were granted by the Government. Of these, three were for the exploitation of iron deposits and the remainder for copper. Most of the mines are in the development stage, except the Matahambre mines and those of Asiento Viejo.

The Matahambre mines were opened in April 1913 and have been under continuous development since that date, producing a total of 90,000 tons of ore. At present 500 men are employed in mining 3000 tons of ore per month. The ore, chalcopyrite, is sorted at the mine into two grades; that containing more than 10% copper is shipped to the United States, while that assaying less than 10% is stored for future treatment. Average shipping ore contains 15% copper and one ounce of silver per ton. The ore is hauled by wagon 11 miles to the coast, where it is loaded on steamers. Negotiations are pending for the building of an aerial tramway, 7 miles long, to replace the haulage of ore with teams.

The Asiento Viejo mines have shipped some high-grade ore but are handicapped by the difficulty of transporting the ore to the coast. Many small mines are being developed but none has reached the stage of production. The eastern province is the oldest and most important mining district of the island. Here are mines of iron, ferro-manganese, and copper. At Santiago de Cuba is the mine of the Cuba Copper Co., formerly the El Cobre. This was the first copper mine worked by white men in the Western hemisphere, its history dating back to 1532, when it was opened by the Spaniards. Operations were intermittent until after the Spanish-American war, when it was acquired by American capital.

The Jaraguá Iron Co. and the Spanish-American Iron Co. are large producers of iron ore. Some ferro-manganese ore has been mined owing to its rapid increase in value in the United States. Practically no gold nor silver is mined on the island. Prospecting for oil has been done in La Habana province with encouraging results. A small amount of crude asphalt has been mined and exported. This industry gives promise of developing to considerable importance. The mining laws have been revised and made more favorable to the operator. With the increase of transportation facilities and the development work now in progress, Cuba should increase greatly in importance as a producer of metals within the next few years.

*Excerpt from 'Boletín de Minas' published by Secretaría de Agricultura, Comercio y Trabajo de Republica de Cuba.

Mining in Colorado

By George J. Bancroft

The advancement in mining in Colorado this fall has been steady and along well-worn grooves. Leadville is hoisting 2500 tons daily. Cripple Creek is producing over a million dollars per month. The northern counties are keeping up production and bringing in new or long idle districts. The San Juan is doing the same. The zinc centres, like Rico and Redcliff, are establishing a new high-water mark of production. The big drainage projects, such as the four Leadville pumping schemes and the Roosevelt tunnel at Cripple Creek, are reaping the reward of diligent industry, and ore from freshly-drained ground is now a material factor in the daily production.

There have been few new strikes on the surface this season, but there have been several ore discoveries in old-time producers this fall that are important. Among these the two most noteworthy are the strike at the Columbus in the La Plata mountains and the strike in the Capital Prize at Georgetown.

The La Plata mountains are in the south-west corner of the State. Georgetown is 50 miles west of Denver. Years ago [in 1896] the Columbus was developed under the direction of T. A. Rickard. Financial depression and the death of one of the owners caused a cessation of activities from 1898 till the spring of 1916, when work was resumed on a cross-cut tunnel. Late in August the vein was cut and was found to be 45 ft. wide, the entire width being ore of milling grade. The water in the old workings immediately began to drain into the adit; a raise was started, but progress was slow on account of the down-pour of water. High-grade ore was not anticipated in this enterprise, but some extremely high-grade streaks have been encountered in the raise. This discovery is important because it marks a new producer of substantial proportions.

The Capital-Prize strike is extremely important, for the reason that it has inspired the theory that all of the silver-bearing veins of that locality will become gold-bearing in depth. The strike was made 1700 ft. below the surface. The orebody is both large and rich. I hesitate to quote figures given me by those who have seen the vein or figures that have been published in the local press because they seem too good to be true, but it is sufficient for this review to state that this shoot of gold ore is far better than any discovery in higher levels in the same locality. Hence the theory that the top of the gold zone is, say, 1500 ft. below the surface. Whether this theory is true or not it has caused renewed activity in the vicinity of the Capital-Prize.

One of the praiseworthy lines of advancement that has made notable progress lately is that having to do with 'First Aid' organizations. To Joseph A. Holmes, the first director of the Bureau of Mines, belongs the credit of having started interest in first-aid work. He showed the miners and managers that, in cases of accident, immediate attention is necessary and that it is not safe nor

humane to rely on the delayed attendance of the company physician. The Colorado Fuel & Iron Co. at once adopted his ideas with enthusiasm. First-aid crews were organized and fully equipped, rescue-houses were built at all the mines of the company. A first-aid crew consists of four men and a captain. They are thoroughly trained in all sorts of rescue and first-aid work. A rescue-house consists of a small dispensary and a room so equipped that an operation may be performed, if necessary, before removing the patient to a hospital. Draeger oxygen-helmets are considered very important in rescue-work because the wearer can go into places where there is smoke or gas. The helmets, however, are expensive, and many mines cannot afford them. Following the initiative of the Colorado Fuel & Iron Co., coal

mine after coal mine organized first-aid crews and provided more or less equipment, until now 85% of all the coal mines in the State have first-aid organizations.

Following the lead of the coal mines the metal mines are organizing first-aid crews and providing equipment. The Smuggler at Aspen has a full outfit, including six Draeger helmets and an ex-Government man named Scofield in charge of the work. The Yak Tunnel at Leadville has four crews and a rescue-house. The work is in charge of a trained officer, A. L. Assig. The Smuggler Union at Telluride, the Newhouse Tunnel at Idaho Springs, the Vindicator and the Portland at Cripple Creek are among those that have some sort of a first-aid organization. John Cortellini, the famous lessee at Leadville, keeps a trained nurse named Helen Smith, at Garbut shaft. Miss Smith told me that her principal occupation was dressing cut fingers. "But," she added, "since I have been tying up the cut fingers, there hasn't been a man laid off on account of an infected wound, while before I came there were lots of them."

Colorado is fast becoming a financial centre for oil enterprises. There are now three producing oilfields in Wyoming; the Lost Soldier field is probably a fourth. All of these fields have been financed largely with Colorado capital. To the east of us are the new fields of Kansas, and Colorado men are heavily interested in them. The productive wells are getting closer and closer to the Colorado line. The sulphur deposits of Wyoming are also attracting attention.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

PROBABLE LABOR TROUBLES.—PROGRESS OF DRAINAGE SCHEMES.

The difficulty that has arisen between the local Miners' Union, which is a branch of the Western Federation of Miners, and the operators is rapidly assuming a serious aspect. The Union has demanded a wage increase to \$3.75 and \$4.25 per day and recognition throughout the district. The present uniform wage is \$3.30, but a number of companies operating in the outlying section are paying from \$3.50 to \$4. Mine-owners contend that the time is most inopportune for a wage increase, and they have openly and flatly stated that they will not treat with or in any way recognize the W. F. M. It is reported that the men will strike of their demands are not granted, but the Union leaders deny this by stating that they do not want to strike under any conditions. They are busy organizing the miners, and report that they are having great success, claiming to have secured 700 members within the past three weeks. This active campaign is looked on by operators and businessmen as a forerunner to a strike, should the majority of the miners become members. The situation has taken on such a seriousness that the Commercial Club has assumed an active part in trying to bring about a settlement before the matter reaches a crisis. The State Industrial Commission is also expected to take steps toward adjusting the situation during the week. Notice announcing the demands and intentions of the Union was filed with the Commission last month, and it is reported that the 30 days provided by law to govern the action of employees and employers in the matter of strikes and lock-outs, have nearly expired. After that time, it is feared the Union will call a strike and leave the matter in the hands of the Commission.

Just at this time a strike would mean great depression to the mining industry of the district. Within the year, several large companies have entered the district and have invested large sums re-claiming the flooded areas for development. Of these, two; the Down Town Mines Co., operating through the Penrose, and the Leadville Unit, operating on Fryer hill through the Harvard and Jamie Lee shafts, have practically completed the draining of their territory at heavy cost, and are just entering the prospecting and development stage. The Empire Zinc Co. and the Western Mining Co., who are draining the Pyrene basin through the Greenback and Wolfstone shafts are still pumping. George O. Argall, manager of the Iron Silver Mining Co., who has organized a new concern for unwatering the Mikado and other properties on Iron hill, is just completing re-timbering of the Mikado shaft, and the erection of new surface buildings at the property. Modern machinery for hoisting and pumping has been ordered. None of these enterprises has realized a dollar on the investment, and it is reported that it will be several months before any of them will be on a self-supporting basis. In case a strike is called, and it becomes impossible to secure men without increasing wages and recognizing the union, it is stated that these undertakings will be abandoned, a calamity, the greatness of which cannot be exaggerated.

Aside from these new undertakings, there are a number of companies operating in the district that are shipping such low-grade ore that they claim an increase in their pay-roll would force them to shut-down. Several large iron-manufacturers producers consider that the margin on their ore is less than 50¢ per ton, and in some cases as low as 25¢. These companies

employ several hundred men. A drop in the price of their product would be serious also.

The large companies of the district that are producing high-grade zinc, lead, copper, silver, and gold-bearing ores could afford the demanded increase in wages, and probably would consent to making some advances, but they absolutely refuse to treat with members of the W. F. M. The managers have consulted with the miners in their employ, and have made known their stand in the matter, stating their refusal to recognize the Union or to treat with professional agitators who have been imported to organize the miners, and their willingness to talk things over with their men if on their own responsibility. No promises of higher wages have been made, but it is believed that this stand on the part of the operators will tend to keep the substantial miners of the district—the old-timers—out of the Union.

A large number of the miners in the district consists of a foreign element that is more or less transient. Many of these men have come in from other sections where they belonged to the W. F. M. and have affiliated with the local Union. They are, in a great part, believed to be responsible for the present unrest. The majority of the members of the local Union are foreigners, and are the most enthusiastic over the question of striking. At present, the situation is veiled in uncertainty. No one outside of the Union knows what the intentions of the miners are, and the reports now being circulated throughout the district often prove contradictory. The general opinion is that the final decision will be made by the Union on October 26. In the meantime, many new enterprises that were about to be started have been held, those in charge stating that they will go no further with their plans until the labor question has been settled. Business shows a marked falling-off and money is tight, showing that the people are preparing against the possibility of a strike. Politics have also been dragged into the matter, and it is reported that no steps will be taken until after the elections. Candidates supposedly in sympathy with the Union are up for election to several of the important County offices.

The Down Town Mines Co. has opened a large body of iron-manufacturers ore in the drained area which is being developed through the Penrose shaft. Re-timbering in the shaft is now underway, and it is stated that as soon as this work is completed, a steady extraction of ore will proceed. The pumps installed at the bottom and intermediate stations continue to handle a heavy flow of water, but this is slowly decreasing in volume as the ground drains. The long drift connecting the Penrose with the Coronado is being cleaned-out and re-timbered, preparatory to carrying on extensive developments in that territory. It is reported that the management expects to uncover the important orebodies in that part.

The Wolfstone shaft of the Western Mining Co. has been drained to the bottom at a depth of 1120 ft. Draining of the Greenback shaft adjoining continues, and it is reported that it will be dry within the next two weeks. The Greenback is 1350 ft. deep. The water is now below the 1100-ft. level, and the old steam-pumping plant installed there is being cleaned-up and repaired for service. As soon as it is in operating condition, it will relieve the Layne-Bowler sinking pump now working in the shaft.

The Iron Silver Mining Co., in charge of George O. Argall, is making rapid progress in overhauling the Mikado shaft. The shaft has been fully re-timbered to water-level, just below

the 900-ft. station. A new station, 15 ft. wide, 18 ft. high, and 60 ft. long, is being cut at this point. On the surface improvements to buildings are going on rapidly. The new blacksmith and machine-shop have been erected and equipped. Foundations for a new hoist and compressor are being put in, the machinery being expected during the month. The hoist is the largest that has ever been brought into Colorado.

LORDSBURG, NEW MEXICO

GENERAL CONDITIONS.—CHINO, BURRO MOUNTAIN, BONNEY, OCTO, AND EIGHTY-FIVE COPPER MINES.—OTHER DISTRICTS.

During the recent impetus given new mining enterprises throughout the South-west the State of New Mexico has remained practically immune. There have been no booms of bonanza strikes to cause a rush. Mining in New Mexico is progressing along substantial and encouraging lines. The two

had been encountered. The Bonney is one of the promising mines in this district. The copper ore is the highest grade and of the best shipping quality, running well in gold and silver. About 20 men are on the pay-roll.

At the Lee's Peak mine of the Octo Mining & Milling Co. Wright brothers of Bisbee, Arizona, are engaged in sinking a 500-ft. shaft under contract. At a depth of 90 ft. water was struck, for which pumping machinery is now on the way. A new steam hoist has been received at the mine, and much new equipment is being purchased. California and West Virginia men are financing the Octo company.

The Eighty-Five Mining Co. is producing about 400 tons of ore daily, and has completed sinking to the 5th level, on which extensive development is being done. The company is installing the second unit of its power-plant, having received another 500-hp. Lyons-Atlas, crude-oil burning Diesel-type engine. Experiments are being made at El Paso by J. W.

HAULING ORE AT THE NIAGARA TUNNEL OF THE BURRO MOUNTAIN COPPER CO.

largest metal-mining companies in the State, Chino and Burro Mountain, are making good headway. Few new companies are entering the State, but old ones are returning to activity, while formerly dormant and operating companies are enlarging their outputs or developing capacities.

The Chino Copper Co. has appropriated \$1,250,000 for the enlargement of its mill, and constant changes and improvements are being made at the Hurley plant. The company is keeping its cost down to 7.25c. per lb. for copper, selling it for about 27c.

Construction is paramount at Tyrone, where the Burro Mountain company is mining and milling low-grade copper ore. The company store, which is one of the largest in the State, is nearing completion. The offices and handsome school building are indicative of big things to come at Tyrone. The 1000-ton capacity mill is being operated and ore is being hauled by way of the Niagara tunnel from the mines at Leopold and Tyrone.

In the Lordsburg district Chicago interests have taken hold of the Bonney mine, and preparations are being made for extensive operations in the near future. The indebtedness against the property has been extended, and the mine is substantially financed. During the past month the No. 3 shaft was unwatered, revealing high-grade ore on the 4th level, where operations were suspended some time ago after water

Crowdus, prior to making a decision on the erection of an ore treatment plant at the 85 mine.

Steeplerock is the scene of several new enterprises that are opening mines near the Carlisle. While activity is comparatively light, the centre promises to open on a large scale after the first of the new year.

The Phelps, Dodge & Co. continue development in the Organ district, east of Las Cruces. G. Fraser-Campbell is in charge of the work.

The Pintado Consolidated Copper Co. at Santa Rosa, Guadalupe county, is erecting a 50-ton experimental mill to try methods of treating the copper ore, including leaching.

The McGee company, operating a lead mine at Steins, is buying new machinery and doing considerable work.—The Volcano mine is under option to Cincinnati interests.

At Kingston, the Virginia, Sawpit, Snow Storm, and Lucky Strike mines are all being worked on a small scale. On the Bullion Hill property two adits are being driven.

Shipments of manganese ore continue from the mines at Boston hill, adjoining Silver City. The ore is sent to Chicago, Illinois.

The old Victorio mines at Gage are being opened again by El Paso capitalists. Andrew Bain is in charge of the work.

The Mogollon silver-gold district of Socorro county is regularly covered in the news section of the Press.

DEADWOOD, SOUTH DAKOTA

RESUMPTION AT THE PURITAN.—TUNGSTEN AND CYANIDING AT THE HOMESTAKE.—TROJAN, RELIANCE, HEIDELBERG, ORO HONDO, AND CUSTER PEAK MINES.

Work has been resumed at the Puritan mine, at the head of west Strawberry gulch. Operations are being undertaken by the New Puritan Mining Co., of which John McGoffin is general manager and John R. Russell secretary. Both are residents of Deadwood. Finances are coming from eastern South Dakota, where good crops and prosperous business conditions have been the rule for years past. The shaft has been sunk to a point below the quartzite, into the schists, and a cross-cut is being driven west to explore a mineralized territory disclosed in stopes above. The ore contains silver and lead—the latter in small quantities—and it is thought will make a good concentrate by flotation.

Tungsten production continues at the Homestake; in fact this company is the largest Black Hills producer of the black concentrate at present operating. The ore is hauled by teams from the workings on north Lead hill and delivered to a crusher near the Star shaft. After crushing, it passes to a belt-conveyor, from which the high-grade ore is hand-picked and the low-grade fed to a 5-stamp mill. In front of the battery is a short amalgamating-plate where some free gold is saved. Concentration is accomplished on a Willey sand-table and two Deister sliming tables. About 20 tons per day is treated. It is stated that the ore contains enough gold to reimburse the company for all expenditure of its milling and mining, thus leaving the tungsten concentrate as clear profit. A high saving of the gold-content is effected, as the tailing from the mill goes to the cyanide department.

Three additional tube-mills are to be installed in the fine-grinding plant at the Homestake. This will practically double the capacity of the unit, and permit of the grinding of all of the sand originating in the stamp-mills at Lead. Fine grinding has paid well at Homestake. In addition to the extra saving by amalgamation—the re-ground product passes over amalgamating plates—increased extraction has been noted at cyanide plant No. 1, where the sand is treated by leaching. The company's metallurgists endeavor to feed to this plant a sand product just as fine as it is possible to leach within reasonable time. The slime plant has long been noted for its high efficiency, so fine sand and slime are the products most sought for as feed for the cyanide department.

That the Trojan Mining Co. is going whole-heartedly into the treatment of custom ores is attested by the facilities being provided for their reduction. First is a three-rail railroad track convenient for either narrow or broad-gauge ore-cars of the C. & N. W. or C. B. & Q. On this track will be a scale for weighing the carload lots. From the cars the ore will drop to underground pockets and thence be led to a crusher, and next to a mechanical sampler; then will drop to underground bins—in reality old stopes—of several thousand tons' capacity. This equipment will cost somewhere between \$12,000 and \$15,000. This expenditure indicates that the company's officials have confidence in the district's ability to continue to produce ores amenable to cyanide treatment. At the mill, additional capacity will be secured by what will be almost a complete rehabilitation of the slime department. This will include a tube-mill, classifier, thickener, agitators, and a revolving-drum filter. The plant's daily duty is now about 350 ton.

M. C. Bowman, general manager of the Reliance up to the time of its closing in the middle of September, has gone to the Blsmarck mine, adjoining the Wasp No. 2, and hopes to be able to start that mill within a few months. The plant is well suited to the ores, i. e. conveniently situated to the mine, and it was demonstrated under former management that mining and milling could be conducted for a little under \$1.20 per ton. Thus a 75% recovery on \$3 ore, when 200 tons daily are treated, would result in a good profit being earned.

At the Heidelberg, what is probably the most important development yet recorded, was recently made when the west cross-cut encountered a vein assaying as high as \$40 to \$50 for about 18 in., and with wall rocks enriched to pay-ore for 5 or 6 ft. on each side. The cross-cut was continued through the ore and drifts driven a few feet in each direction. Effort is being made to find the vein on the surface. Eastern people have been given an option on 51% of the capital shares of the corporation, with the understanding that the entire amount of money will be spent under the supervision of the purchaser, in further development of the property. This is the ground that a few years ago was taken over by a syndicate of local people, encouraged by the Deadwood Business club, and on which something over \$15,000 of local money has been spent. Its success would do much to stimulate local interest in mining ventures.

Sinking is now under way at the Custer Peak copper mine, where at a depth of 250 ft. oxidized material was found in lateral work. The management intends to put the shaft down to the zone of secondary enrichment. Surface geology and mine developments to date seemingly indicate that a copper mine of merit will be uncovered. The company owns a large area, covering the vein for over 3 miles.

Sinking is again to be resumed at the Oro Hondo, this time with the 3500-ft. level as the objective point; the shaft is now 2000 ft. deep. In past months a great deal of diamond-drilling has been done. The additional sinking will make necessary the purchase of a large hoist, and in this connection it is expected that the top of the shaft, for 40 or 50 ft., will be concreted, and a new and higher head-frame, probably of steel, erected.

SUTTER CREEK, CALIFORNIA

THE STRIKE SITUATION AT THE END OF OCTOBER.

There appears to be little change in the strike situation (October 29), and with the exception of guards, pump-men, engineers, and a few shaft-men, all the large mines of the county, except the three who met the men's demands prior to the strike, are idle. The Northern Amador County Merchants Association has given its support to petitions now being circulated, by which many of the miners are expressing their willingness to return to work on the old basis. The local Union leaders declare that men returning to work or signing such petitions forfeit their Union membership, and reports are at variance as to whether any Union men are signing up. It was reported that 15 men returned to the South Eureka on Friday morning, and half as many to the Central Eureka, but this report proved untrue. Now, it is claimed that 30 or 40 men will resume work at the Bunker Hill mine on Monday morning, and that more are ready to return when satisfied that they will be unmolested by the strikers. It is claimed that so many men have left the county since the strike commenced on September 19, that all the mines will be short-handed even if a satisfactory settlement is arrived at. U. S. Deputy-Marshall Bohm is still here, and is said to have served at least fifty of the strikers with papers from the U. S. District Court restraining them from committing violence pending the hearing to be had in San Francisco on Monday, the 30th, when cause must be shown why permanent injunctions may not be issued. Some of the strikers have attempted to elude the Marshal and his deputies in the service of the papers, and others signify their contempt by tearing the documents to pieces as soon as served, but the Marshal appears tireless in his efforts to accomplish his purpose by use of both force and strategy, having for the men at unexpected places and even using "Jim Jones" once to "cock" a man to gather the fragments of the paper he had thrown to the ground and tramped upon. Denver officials of the Western Federation arrived here yesterday. Everybody is getting tired of the whole business and wishes that the strike were settled.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALABAMA

In Bulletin 640-1 of the U. S. Geological Survey, Edson S. Bastin describes the Gold Log mine near Talladega. The property had been worked intermittently for 70 years previous to the present owners acquiring it in June of 1915. E. A. Thomas is manager of the Gold Log Mining Co. The vein has been explored by an adit 250 ft. long, from which is an incline 320 ft. deep. Stopes average 6 ft. in width. The ore, in schist, consists of (1) irregularly interlocking white to light-gray quartz, white to pale-pink calcite, and minor quantities of sulphides and free gold; and (2) schist partly replaced by some or all of these minerals. The principal sulphide noted is chalcocite. A characteristic of the deposit is that wide shoots pinch out or decrease greatly within short distances. Water power drives the ten 750-lb. stamps, etc. Gold, averaging \$4 per ton, is saved on copper plates and blankets. Concentration is not attempted. The daily capacity is 25 tons.

ARIZONA

Some complaint has been made throughout Arizona mining districts to the effect that the smelters refuse to receive small ore shipments from the smaller shippers, says the Arizona State Bureau of Mines. There is a congestion of ore at all the smelting plants at present, which is the cause of the curtailment of shipments. However, many of the small operators, whose properties are under development, claim the smelters have not refused to treat the increased tonnage of the larger mines. The small operator, as a rule, depends on the sale of ore to enable him to advance his development, and when the only available markets are closed to him, he is severely handicapped. To make a prospect produce sufficient ore to pay for its development is a method that enhances the mining industry, and should be encouraged and not retarded. It would seem that some preference should be given those small producers whose output is incidental to development, and the marketing of which is essential to continuance of operations. The big producer is relied on to keep the smelter in operation, and it is easy to understand the good relations between the two; at the same time the growth of the mining industry depends on the coming-in of new producers, many of which have to pass through a difficult period of early development. To encourage the small ore shippers is to make possible the opening of new mines.

There is little doubt of the willingness of the larger mining companies to assist the small ore shippers in the development of their properties, but small shipments of ore, coming irregularly, so break up the routine of the smelter operation that naturally the smelters prefer large and regular shipments. The small shipment requires as much clerical work, computation, etc., to handle as does a large shipment, but nets the same margin. The fact that the smelters are already producing more metal than the refineries can handle practically allows them to choose, to some extent, their ores, but the Bureau has never yet seen the time when the smelters could possibly handle the ores of the smaller shippers, that they did not only throw open their doors, but came out and invited them to ship.

BISBEE. The Shattuck-Arizona mine is producing daily 550 tons of copper ore and 50 tons of lead ore. General conditions underground are good, with important developments on the west side. The output in September was 1,566,446 lb. of cop-

per, 26,928 oz. of silver, and 419 oz. of gold, giving a profit of \$260,028.

(Special Correspondence.)—Chloride is suffering from too much lot-jumping, the inevitable accompaniment of a rush into a new mining camp. Some of the choicest business property in town is being taken by the jumpers, and there seems to be no recourse except by violence. Gun-play is fairly frequent, but so far both parties to the dispute have refrained from making work for the coroner. It is feared that trouble will result unless some way is found to end the jumping. The trouble was invited by the high prices asked for town property, and the questionable title to much of it. Lots that sold for a few hundred dollars six months ago or less, are now held for several thousand dollars. One choice corner lot is being held for \$8000.

The local water company is preparing to make large extensions and improvements to take care of its rapidly-growing business. A new reservoir is to be built at the head of Tennessee avenue, overlooking the business section of the town, giving good pressure for fighting fires. The town is spreading in a southerly direction, and the water-mains have long since ceased to reach a large portion of the newly-built area, which has had to rely for its water supply on the time honored water-wagon.

The power-line being constructed is within five miles of Chloride and the gap is being reduced at the rate of about half a mile daily.

The Black Jack ore is now passing through the streets every day en route to the Needles smelter. An army of burros is engaged in packing this ore from the mine to what is known as Tramway Landing, where it is loaded on wagons that haul it to the railroad here.

Another property is to be started in the early part of this week; this is the Emerson, centrally situated and of considerable merit. E. M. Binds of Los Angeles recently reported favorably on it, and on his recommendation capitalists have taken it over.

Chloride, October 23.

GLOBE. Three blast-furnaces and two converters are working at the Old Dominion, yielding 40 to 50 tons of copper per day. As the International smelter at Miami cannot receive more concentrate at present, this product is stored at the mill. Several alterations are being made in the concentrating plant. A Diesel engine is to be erected near the A shaft. The daily output of ore is 1000 tons, one-third being smelted direct. The mine's flow of water is now under 6,000,000 gal. daily, a decrease due to the Arizona Commercial doing some pumping. The latter company has received a new pump for its 14th level, and another one is on its way. This will allow for sinking to No. 16. Monthly profits average \$47,000 from 420,000 lb. of copper.

MIAMI. The Porphyry Copper Co. has been organized by J. D. Coplen and others, with a capital of 1,500,000 \$1 shares, to develop 13 claims west of the Inspiration Consolidated mine. Some work has already opened carbonate ore.

At the Miami Consolidated, adjoining the Live Oak mine of the Inspiration Consolidated, a new two-compartment shaft is being sunk. Ore is also being extracted. The Star Drill Machine Co. of Akron, Ohio, is sending two large churn-drills for prospecting.

By improvements to its tailing ponds the Inspiration Consolidated will save a great deal of water.

ARKANSAS

EVERTON. Three or more good zinc mines have been opened in this district, a 150-ton mill is being constructed at the Marguerite mine, and a good future is expected for the area.

KINGDON SPRINGS. Erection records in mill building have been common of late, in the south-western zinc region, but the new 100-ton plant at the Beaty mine, owned by O. W. Killam of Locust Grove, Oklahoma, was put up in 18 days. The ore is high grade.

RUSH. At the Edith mine last week a 9-hour shift at the mill produced 31 tons of concentrate. The new 150-ton mill is working well.

CALIFORNIA

CERRO GORDO. Development of the rich lead-silver shoot in the Cerro Gordo Mining & Smelting Co.'s property continues, while zinc ore is being shipped to smelters.

IN THE SHADOW CREEK DISTRICT OF MADERA COUNTY, CALIFORNIA, 60 MILES FROM BISHOP, ALTITUDE FROM 8000 TO 10,000 FEET. THE WHITE ROCK IN THIS PICTURE IS THE MINERAL-BEARING ZONE, CONTAINING COPPER, LEAD, AND ZINC. TUNGSTEN (WOLFRAMITE) IS FOUND NEARBY.

GRASS VALLEY. Ten more stamps have been ordered for the Golden Center mine and twenty for the Allison Ranch mine, which is controlled by the former company. Erection of buildings is under way.

HEBOULT. At the electric smelter the Noble Electric Steel Co. has three furnaces in operation, making ferro-manganese, ferro-chrome, and ferro-silicon. The company receives its raw minerals from various parts of the State.

PLYMOUTH. The September output of the Plymouth Consolidated was as under:

Ore milled, tons	6,900
Value of gold	\$44,621
Working expenses	25,351
Development charges	6,717
Surplus	12,552
Other expenditure	8,628

The new hoist is almost in place. The club-house, which was presented to the town by the company, is proving of great social benefit to employees and others. Dwellings for the men have been built.

ST. LOUIS. For violation of the Caminetti act, which guards against depositing tailing from hydraulic operations in navigable streams, J. Conlan of St. Louis in Sierra county was fined \$50 last week by Federal Judge Dooling. Tailing from sluicing went into Slate creek, then to the Yuba and Sacramento rivers.

SOSORA. A cross-cut from a winze in the Omega mine has opened free gold and mineralized ore assaying from \$10 to

\$60 per ton. A wide shoot is expected, as above it was over 24 ft. across. Lange & Hussey are lessees from Ayers & Harter.

COLORADO

BOULDER. The Colorado Power Co. states that during September, Boulder and Gilpin county mines consumed 660,000 kw.-hr. of current, compared with 286,000 kw.-hr. in that month of 1915. Fully 68% of the increase is from the Boulder mines. The tungsten boom was mostly responsible, though gold and silver mines contributed.

For the sum of \$20,000, E. J. Lavino & Co. of Philadelphia bought four tungsten claims from R. Kermack and H. De Vries. The Tungsten Metals Co. has had a bond and lease on the property, and will continue to operate, and may eventually buy the ground from the new owners. New equipment is to be ordered.

LEADVILLE. An important discovery of gold-silver-copper ore is reported in the lower adit of the Fidelity Gold Mining Co. on Bull hill, in the Lackawanna district. The gold-content is 10 oz. per ton. A mill is to be erected in the spring.

Owners of the Tarsus mine on Yankee hill have opened on the 650-ft. level a shoot assaying 89 oz. silver, 14% lead, and 20% copper. Prospects for persistence are considered good.

PUEBLO. In its 24th annual report the Colorado Fuel & Iron Co. states that the gross revenue was \$25,626,606, an increase of \$9,018,566, or 54%. A good deal of mention is made of sociological relations of the employees.

IDAHO

ADAIR. Development of copper properties in the east Coeur d'Alene district continues unabated. Results at the Montana-Idaho and Richmond mines are satisfactory.

BURKE. The new east lead-silver vein in the Hecla mine has been opened for 850 ft. on No. 3 level. Above this a raise is up 600 ft. in ore. The grade is high, with only traces of zinc.

MURRAY. A trial of the re-modeled mill at the Golden Chest gold-tungsten mine proved satisfactory last week.

MICHIGAN

HOUGHTON. Nearly 1600 new men have been engaged by the Calumet & Hecla subsidiaries during the past summer, but it is said that the proportion of transient men is greater than before. Some Mexicans have been employed.

MISSOURI

JOLIEN. Prices for zinc and lead ores remained the same last week. The first cold spell of the season caught some producers unprepared, reducing the output. The yield of the Missouri-Kansas-Oklahoma region was 6125 tons of blende and 893 tons of lead, averaging \$65 and \$85 per ton respectively. The total value was \$479,732.

MONTANA

BUTTE. During the third quarter of 1916 the North Butte company produced 5,954,685 lb. of copper, 247,833 oz. of silver, and 1002 oz. of gold. The profit was \$587,424.

At a depth of 1000 ft. in the Butte & Zenith City a cross-cut has passed through two promising veins.

GRANT FALLS. Two of the five units at the Anaconda company's electrolytic zinc plant are yielding 60 tons of zinc daily, 10 tons above the calculated capacity. A bag-house, with 1440 bags, costing \$100,000, is being erected. This plant will collect lead fume from reverberatories.

SALTUS. At the beginning of next year the Tarbox company will commence ore shipments.

TROY. According to Robert Gregg, interviewed by the Northwestern Mining News Service, a brief review of activities around Troy will convince anyone that it is one of the coming important mining regions. There are hundreds of men em-

ployed at the different properties, and supplies and equipment are being sent in by the train-load. The attention of investors also is being attracted to the district, and engineers are scouring the country for miles around in search of promising holdings that are for sale.

NEVADA

BRISTOL. A number of Utah people are operating successfully at this place, which is 14 miles from Pioche. The ore contains lead, silver, and copper, and is oxidized to a considerable depth. J. M. Hill, of the U. S. Geological Survey, recently visited the district.

(Special Correspondence.)—Preparations have been completed for the building of a sampling plant at Jean, with a capacity of 200 tons per 10-hour day. It will be particularly devoted to sampling ore from Goodsprings and properties to the south along the Salt Lake Route. Utah people are financing the enterprise.

Operations have been resumed by the Dawn Mining Co., situated on the eastern slope of Potosi mountain. Some high-grade zinc ore has been uncovered, and developments will be pressed with an increased number of men. Albert Munzberock is superintendent.

The Boss Mining Co. is busy preparing plans for the new mill. The testing plant is operated steadily under management of M. Goodwin, and is making a satisfactory recovery of gold and platinum. The proposed mill will have a daily capacity of 10 tons. About 800 sacks of high-grade platinum ore is available for treatment, in addition to the regular mine product.

The Potosi is shipping approximately 1200 tons of lead and zinc ore per month, a considerable proportion of this being high grade. It is controlled by the Empire Zinc Co., and was inspected last week by the company's Western manager, C. J. Brown.

The Searchlight district is again receiving recognition from capital. At the Quartette much new work is going on, and it is reported that the New York owners are preparing to operate with 100 men. G. F. Cohan is preparing to resume at the Duplex.—The shaft of the Big Casino is being sunk an additional 100 ft. in concentrating ore of good grade.—Work is to be resumed at once by the Searchlight Mining & Milling Co.—Several other properties north and east of the camp are decidedly active.

A 42-in. vein of \$75 gold-silver ore has been encountered in the Carnation claim, El Dorado canyon, at a depth of 20 ft. Gold largely predominates. The Eldorado Empire, Wall Street, Eldorado Nevada, Cluff-Era, Enterprise-Rand, and a number of other claims are actively worked. A new camp, known as Nelson, is growing.

Goodsprings, October 24.

GOODSPRINGS. A dividend of 2c. per share will be paid on November 10 by the Boss company. Two shifts are working in the lower adit to get under the copper ore opened above.

SEARCHLIGHT. The Searchlight cyanide-plant in charge of N. H. Barton, is working to capacity, and making a good recovery on tailing from the Quartette stamp-mill.

TONOPAH. During the third week of October the district produced 9864 tons of ore valued at \$193,492. Some September yields were as follows:

Mine	Tons	Bullion, oz.	Profit
Belmont	11,904	201,474	\$93,936
Extension	9,545	171,179	64,896
Jim Butler	3,552	37,107
Tonopah	8,095	150,780	62,779

The yield for the week ended October 28 was 9959 tons valued at \$195,202. Development at the Belmont continues entirely satisfactory.—From 950 to 1540 ft. in the Extension's Victor mine results are good.—Improvement is reported from the Jim Butler.—For the quarter ended August

31, the Tonopah Mining Co.'s profit was \$122,713, plus \$44,604 from the Tonopah Placers Co. The dividend amounted to \$150,000. Cash on hand is \$36,172.

VIRGINIA CITY. The Mexican Gold & Silver Mining Co. has issued a circular in which it is stated that the last assessment levied on Mexican shares was nearly a year ago, on December 22, 1915. The discovery of ore in the Union Con., and the milling of the same in the Mexican mill, has netted the company a substantial profit, enough, in fact, to enable it to pay its pumping charges and explore the 2500 and 2700-ft. levels without calling on shareholders for funds during 1916. Exploration of the 2500-ft. level to the west has resulted in no discovery of importance. At 2700 ft. a well-defined formation has been exposed, showing every indication of being productive in depth. The pumps to lower the water from the present level (the 2700-ft.) to the 2900-ft. are now installed, and will start work probably about November 1, thus clearing the five north-end mines of the Comstock of water to the latter depth. The winze in the Mexican ground between the 2700 and 2900-ft. levels has been equipped with a hoist, and as the water-level is lowered exploration will be immediately commenced. It is firmly believed that something of importance will be discovered. Large quantities of mill supplies have been purchased and are now on hand, a single car of cyanide having been secured during the past week at a cost of over \$9000. In view of the steady increase of prices due to the War, and the difficulty of obtaining chemicals at all at critical times, this policy, it is considered, is fully justified, and will result in an ultimate saving to shareholders.

NEW MEXICO

On page 675 of this issue will be found a general review of mining in this State.

(Special Correspondence.)—Work has been resumed at the Gold Dust claims, situated in the south part of the district. The property has had 1800 ft. of adits driven, encountering

SCENE AT MOGOLLON, NEW MEXICO.

two orebodies. These are to be explored further and the main adit extended to the centre of the property.

Mr. Cockran, of A. Leschen & Sons Co., who is supplying material for an aerial wire-rope tram from the Pacific mine to the plant of Socorro Mining & Milling Co., is here, superintending installation. Rollers and rim work are being placed on standards and terminals; practically all the woodwork has been completed. The tram will have a length of one mile and a capacity of 10 tons per hour.

The Oaks Company is getting in supplies and other material preparatory to starting work on its drainage and transportation tunnel on Mineral creek. When completed it will be the largest and longest opening in the district, and will cut the principal orebodies at depths of 1400 to 1800 ft., and be the means of effecting a great economy in future operations.

It is planned to have a large capacity plant at the portal, and eventually centralize all metallurgical operations of the district at this point. The topography of the site is well adapted to the consummation of this scheme.

F. L. Ransome, of the U. S. Geological Survey, spent the week in camp checking geological work being done. An appreciable territory will have been covered when the area is completed.

Mogollon, October 17.

TENNESSEE

In the October 'Resources of Tennessee,' is a 23-page paper by W. C. Phalen, of the U. S. Geological Survey, on the conservation of phosphate rock in this State. Tennessee rock was first placed on the market in 1894. In 1914 Florida produced 78%, South Carolina 4%, and Tennessee 18% of the phosphate rock used in the United States and exported. The brown rock is the most important in Tennessee, occurring in Maury, Giles, Hickman, Lewis, and Sumner counties. The largest deposits are near Mount Pleasant in Maury county. They are termed 'blanket' and 'collar' deposits. Changes in methods of mining and preparation will leave little or no wasted rock in the ground. Clay, chert, and limestone must be removed before going to market. Overburden is removed by drag-line excavators and hydraulic lifting. Hand mining is much in vogue, due to the occurrence. The ore contains over 20% phosphoric acid and up to 70% phosphate of lime.

TEXAS

(Special Correspondence.)—Records of the Collector of Customs for the El Paso district show that there was a large falling-off in imports of ores and metals from Mexico through here during the first seven months of the current year, when compared with a corresponding period of last year. These imports for the period ended July 31, 1916, were as follows: January, gold ore \$2664, gold bullion \$17,827; February, ore \$2122, bullion \$10,705; March, ore \$10,631, bullion \$532; April, ore \$6857, bullion \$731; May, ore \$3250, bullion \$348; June, ore \$2348, bullion \$351. July, ore \$1029, bullion \$4116; making a total of \$28,931 gold ore and \$64,601 of gold bullion. During the same period of 1915 there was imported gold ore valued at \$69,950, and gold bullion worth \$1,188,305.

January silver ore imports were worth \$14,971, and silver bullion \$197,176; February, ore \$140,035, bullion \$1291; March, ore \$114,837, bullion \$20,300; April, ore \$45,607, bullion \$3790; May, ore \$29,041, bullion \$21,127; June, ore \$8445, bullion \$4222; July, ore \$11,186, bullion \$38,047; a total of \$361,423 of silver ore, and \$284,952 of silver bullion. During the first seven months of 1915 the silver ore imported had a value of \$472,172 and the silver bullion \$2,419,635.

Imports of copper ore amounted to 12,139 tons, valued at \$117,811. Last year, from January to July, inclusive, imports of the same product were 4995 tons worth \$86,395. Copper matte brought over this year was 683 tons, valued at \$12,021, while last year 798 tons was imported, worth \$35,642. This, the greatest movement of copper ores, took place in March, April, and May.

Imports of lead ores were as follows: January, 508 tons, value \$1753; February, 2212 tons, \$21,570; March, 6470 tons, \$36,512; April, 5948 tons, \$54,618; May, 3831 tons, \$19,843; June, 360 tons, \$1212; July, 812 tons \$4921; a total of 20,175 tons, valued at \$145,529. Last year from January to July, inclusive, imports of lead ores were 26,395 tons worth \$121,169.

Following is the record of zinc-ore importations by months: January, 30 tons, value \$972; February, 977 tons, \$4490; March, 3641 tons, \$122,096; April, 1349 tons, \$126,781; May, 2186 tons, \$55,578; and June, 5162 tons, \$110,766 (the figures for July are not available); total, 16,848 tons, worth \$450,892. During the same period of 1915 imports of zinc amounted to 12,699 tons, valued at \$182,218.

El Paso, October 23.

UTAH

ALTA. Progress in the Alta Tunnel & Transportation Co.'s tunnel is 8 ft. daily. Drilling in the limestone is a little easier lately. Results of this work are being watched with interest by the whole district.

MIDVALE. The new plant of the Midvale Minerals Co. costing \$100,000, to treat between 300 and 400 tons daily of lead-zinc tailing at the old U. S. smelter, has commenced treatment. Oil flotation is employed, using Janney cells.

PROMONTORY. At the United Promontory the shaft is down 128 ft. Samples of ore assayed 6% copper, 9 oz. silver, and 51% lead.

EUREKA. In our issue of October 14 we gave the total dividends of the Chief Consolidated Mining Co. at \$283,000; this should have been \$483,368. With the dividends that will be paid on November 2, of \$44,149, the total will then be \$527,518.

SALT LAKE CITY. Affairs of the Ohio Copper Co. are still in a tangle, resulting in much discussion as to its future, and proposed re-organization. On October 6 the International & Intercontinental Mining & Refining Corporation of 60 Wall Street, New York, sent a circular to shareholders. On August 30 the property was sold on foreclosure for \$750,000. The Corporation was unsuccessful in its application to postpone the sale, although the Ohio company was in a position to pay its debts and interest, and then have a substantial balance. The day following the sale the right to redeem the property was sold by the trustees in bankruptcy for \$40,000. Under the State laws the company had the right to redeem at any time within six months after the date of sale. The Stockholders' Protective Committee was being formed at the end of August and a re-organization plan was in preparation. Confirmation of sale in foreclosure and sale of the equity of redemption was adjourned to October 13, at which time the Court must be convinced that the stockholders intend to protect their own interests or the sale will doubtless be confirmed. At that date there would be the one chance for stockholders to save their property. On September 30, U. S. District Judge Manton granted the Corporation leave to intervene in the bankruptcy proceeding for protection of stockholders. The Judge pointed out that although the property sold for \$750,000, leaving an apparent deficiency of \$700,000, yet that deficiency has since been reduced to \$400,000 by royalties and rentals by lease of the property. He also commented on the non-paid stock, a valuable asset. Holders are urged to deposit their stock with the Central Trust Co. of 54 Wall street, New York.

WASHINGTON

REPUBLIC. Owing to the ore in the San Poil mine yielding only \$6.75 per ton, against \$8 expected, work has been suspended by the lessee, the West Hill Mining Co. of Spokane.

CANADA

BRITISH COLUMBIA

Silverton. The Standard Silver-Lead company pays 2½c. per share on November 10. The new orebody in the Alpha claim continues to open well. In No. 5 adit, 3 ft. of clean galena has been cut.

ONTARIO

COBALT. The Mining Corporation of Canada is operating its high-grade mill. It differs radically from the two other high-grade plants at Cobalt, in that amalgamation plays no part in the treatment, nor is the ore crushed in cyanide solution. The ore is first slined in tube-mill, and after a preliminary treatment in two stages is dewatered and washed on an Oliver filter, then given cyanide treatment, and again filtered and washed on a second Oliver filter. The silver is precipitated from the solution by sodium sulphide instead of aluminum dust, and the resulting silver sulphide precipitated, desulphurized, pumped to filter-presses, and refined in reverbera-

tory-furnaces to a high-grade bullion ready for shipment in bars to London.

LANGMUIR. The nickel deposits in this township have been optioned to the International Nickel Co., which will prospect by diamond-drilling.

PORCUPINE. During the quarter ended September 30, the McIntyre Porcupine Mines Co. made a profit of \$136,084. There was 35,810 tons of \$9.98 ore treated at a cost of \$4.93 per ton. Custom ore amounting to 6877 tons gave a profit of \$28,239, which is included above. Development covered 1062 ft. and 1302 ft. of drilling. At 1000 ft. depth the west drift on the boundary vein was advanced 300 ft. A stope above this level shows 8 to 30 ft. of \$15 ore. The present face is 18 ft. wide. Improvements at the main shaft will be complete early in January. Work from No. 4 and 5 shafts was satisfactory.

KOREA

The Oriental Consolidated reports the following returns for August: 200 stamps worked 29.9 days, crushing 26,895 tons. The gross receipts were \$132,660, and operating costs totaled \$76,722, and improvements, development, etc., cost \$1440, leaving a net profit of \$54,498.

MEXICO

CHIHUAHUA

(Special Correspondence).—At the Alvarado Mining & Milling Co.'s plant the labor is Mexican only. There are only two of the old American staff of the company at Parral, and they are operating five mines, and the plant of 400-ton daily capacity is working full time. The Mexican organization, however, is more efficient than was thought possible until the men were tried. All the staff left for El Paso in January last, after the Santa Isabel affair, and most of them returned in May, resumed operations in June, only to have to leave hurriedly again at the latter part of the month after the Carrizal affair. As the company did not desire to risk again the lives of its American employees, only the manager and another returned in July to resume operations. They found that the native help, after a period of near starvation, was willing to work, and the property has been running at full capacity ever since.

Villa has been active again in the vicinity of Chihuahua City, and there have been many rumors of his approach to attack Parral. It is hoped that he will confine his activities to the north and leave us in peace for a time at least. Conditions are bad, of course, and the entire State is under martial law, and executions are frequent. It seems that there is nothing to do but endure it until there is an end to the Wilson administration in the United States; that, more than any one thing, is considered to have caused these conditions to last as long as they have, with no hope for the future.

Parral, October 10.

The new mining and milling laboratory of the Haileybury School of Mines, Ontario, is nearing completion, and the institution is now getting its machinery and equipment. The laboratory will comprise a complete small-size concentrator, cyanide plant, flotation plant, assay-office, blacksmith, machine, and carpenter shops, and will contain most of the machines usually used in this work. The school has the co-operation of the companies in the Cobalt district and mining-machinery manufacturers, and is always pleased to make arrangements with manufacturers who wish to have their machinery represented in the plant.

The College of Mines and Engineering at the University of Arizona announces short courses for miners. Tuition is free to residents of the State, others pay \$1 per course. Prospectors have five weeks, starting on October 30, field geology two weeks from December 4, assaying ten days from January 3, metallurgists three weeks from January 15, flotation one week from February 5, and miners 6 weeks from February 12.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

DEANE P. MITCHELL is at the Palace.

WALTER STRACHE sailed for Chile on October 21.

GEO. WATKIN EVANS has returned to Seattle from Alaska.

PIERRE BOUCRY has left Alaska to give his services to France.

HALLET R. ROBBINS has returned from California to Vancouver.

WILLIAM DeL. BENEDICT has returned to New York, from California.

FORBES RICKARD has gone to Lovelock, Nevada, on his return from Arizona.

THEODORE HOOVER arrived in New York on the *Philadelphia*, on October 29.

PHILIP ARGALL passed through San Francisco from New Mexico to Denver.

DAVID T. DAY, of the U. S. Bureau of Mines, was in San Francisco this week.

FRED B. ELY has recently visited New York and has left for Vancouver, B. C., to remain indefinitely.

H. E. WEST has returned to San Francisco, and is with the firm of Hamilton, Beauchamp & Woodworth.

J. H. RICKARD is on his way back to Cornwall, from San Francisco, by way of Vancouver and New York.

EDWARD B. DUGHAM has been engaged as superintendent of construction for the Mammoth Copper Mining Co., Kennett, California.

J. N. BULKLEY, of New York, has been appointed consulting engineer to the Kaolin Products Corporation, and will design and supervise the erection of its new plant.

H. W. ALDRICH, superintendent of the leaching plant at Anaconda, has been promoted to superintendent of the blast-furnace and briquette plants; H. J. MAGUIRE succeeds Mr. Aldrich.

F. K. BRUNTON has resigned from the staff of the A. S. & R. Co. at Garfield, Utah, to accept a position as assistant superintendent of the Consolidated Arizona Smelting Co. at Humboldt, Arizona.

JOHN V. N. DORR has been awarded the John Scott medal by the City of Philadelphia, acting on the advice of the Franklin Institute, for the invention of his classifier, thickener, and agitator.

EDWARD A. STEINBERG, recent foreman of the United Comstock Pumping Association, who was injured July 4 in Virginia City, and has been confined to the hospital in Reno, has been removed to the Saint Francis hospital, in San Francisco, for treatment by a specialist.

GEORGE S. RICE, chief mining engineer, and H. M. WOLFLIN, mine-safety engineer, of the U. S. Bureau of Mines, were in San Francisco from October 25 to 28, for the purpose of arranging for a successor to EDWIN HIGGINS, who has resigned as the representative of the Bureau of Mines in the California co-operative work and as chief mine inspector of the Industrial Accident Commission. Mr. Wolflin was first assigned to this work in 1914, and he conducted the preliminary investigation that led up to the adoption of the Mine Safety Rules by the Industrial Accident Commission. Conferences were held with WILL J. FRENCH, commissioner, and Messrs. Rice, Wolflin, and Higgins, the result of which was a decision temporarily to assign Mr. Wolflin to succeed Mr. Higgins until such time as the plans discussed can be gone over with the Director of the Bureau and a permanent assignment made. Mr. Rice left for Los Angeles on the 28th and will return to Washington about November 15 stopping en route at various mining centres where the Bureau of Mines is conducting field investigations.

THE METAL MARKET

METAL PRICES

San Francisco, October 31.

Antimony, cents per pound.....	14.00
Electrolytic copper, cents per pound.....	29.25
Pig lead, cents per pound.....	7.25—8.50
Platinum: soft and hard metal, per ounce.....	\$90—94
Quicksilver, per flask of 75 lb.....	\$80
Spelter, cents per pound.....	12
Tin, cents per pound.....	43
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, October 31.

Antimony: 50% metal, per unit.....	\$1.25
Chromite: 40% and over, f.o.b. cars California, per ton.....	13.00—16.00
Magnetite: crude, per ton.....	8.00
Manganese: 50% (under 35% metal not desired).....	11.00 and up
Tungsten: 60% WO ₃ per unit.....	17.00

At Boulder, Colorado, the tungsten ore market is active, the price being steady at \$17 per unit for standard grades.

New York, October 25.

Antimony: Ore of good quality has sold at \$1.30 per unit in small quantities.

Tungsten: European consumers continue to inquire, but the market has been quieter in regard to actual sales, probably not more than 150 tons having been taken in the week. The nominal quotation is \$17 per unit.

Molybdenite: But little of this ore is available, and there is keen competition for what there is. Quotations are higher at \$1.70 to \$1.80 per lb. for molybdenum sulphide.

EASTERN METAL MARKET

(By wire from New York.)

October 31.—Copper producers are firmer and fairly active, near-by metal is scarce; lead is quiet and firm; dealers buying stragglers spelter.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
Oct. 25.....	67.37
" 26.....	67.37
" 27.....	67.37
" 28.....	67.62
" 29 Sunday.....	67.62
" 30.....	67.75
" 31.....	68.12

Monthly averages

June	56.43	49.03	65.04	Dec.	49.27	55.31

Steadiness and a slight rise is noticeable during the week, backed by a good undertone. The effect of selling from China is felt at times, although the actual amount of silver that changes hands may not be large, for there is always a possibility of the quantity increasing. The mere fact of China assisting with supplies influences other selling, speculators are disposed to take profits, and the Indian Bazaris, whose adverse views as to the future of silver are notorious, at once feel depressed. In these circumstances a certain retrogression in prices (as last week) is a natural outcome.

Silver worth \$125.100 was shipped from San Francisco to the Orient on October 28.

Silver stored by the Tonopah Mining Co. is worth \$131.011, calculating at 50c. per ounce.

June	13.60	19.75	27.47	Dec.	12.75	20.67

Thirty-cent copper is soon to be reported, according to some producers. Prices have stiffened of late. Smelting and refining companies are 600,000 lb. behind with deliveries of metal.

Dividends paid by 11 copper companies during October totaled \$5,772,181, on 3,233,117 shares. In September, 16 companies paid \$24,000,000 on 12,000,000 shares. Greene Cananea pays \$2 per share on November 27.

The American Brass Co., a large consumer (400,000,000 lb. annually) of copper is paying 10% for the last quarter of 1916, making 25% for the year, equal to \$3,750,000 on the capital. By the end of this year the surplus will probably be \$100 per share.

Eastern Metal Market

New York, October 25.

The feature in copper is a persistent and general rumor that a foreign country, presumably Italy, is negotiating for a large quantity. Meanwhile the undertone of the market is strong.

Zinc has reached and passed 10c., although the upward movement now appears to have halted. A heavy business has been done in the past few days, principally with the galvanizers.

Lead is stronger in the West, but obtainable at Eastern points at 7 cents.

Tin is higher despite a quiet market.

Antimony is dull again.

Iron and steel prices continue to advance. In a broad way it may be said that prices of semi-finished steel are \$15 to \$20 per ton higher than a year ago, and those of finished materials, \$20 to \$30 higher; and it is highly probable that higher levels will be reached.

The pig-iron market has been highly excited this past week, and quotations have jumped from \$1 to \$3 per ton. The coke market is even more agitated, sales of prompt foundry and furnace coke having been made at \$6 to \$7 per ton, with nearly \$8 asked. The car shortage has interfered with deliveries of contract coke, and consumers have been obliged to buy spot fuel. Thousands of tons of shell-steel are still under negotiation.

The metal-working machinery trade is near a normal basis in all save prices. The builders and dealers in machine-tools have been in convention in New York this week, devoting much discussion to *post-bellum* possibilities in their line. The dealers point out that prices must be lower if they are to successfully combat the flood of second-hand machines that the munitions' makers will place on the market, and compete with the new and cheaper machines which the War brought into being. It is estimated that 100 more firms are now making machine-tools than were in the business two years ago.

ZINC

Early last week it was remarked that the producers had set their minds on obtaining 10c. for spelter, and in the face of a fairly good demand they appeared unwilling to sell. However that may be, the fact is that the price has reached and exceeded 10c., also that in the past four or five days an extremely large tonnage has been bought, mostly of the galvanizing grades. The brass mills have shown little interest. Spot was quoted yesterday, the 24th, at 10.25c., New York, and 10c., St. Louis, November at 10.12½c., New York, and first quarter at 9.87½ to 10c. The market showed an advancing tendency until yesterday, when it halted, much to the disappointment of the sellers. The London spot quotation yesterday was £54, or £1 higher than a week previous. Exports continue on an enormous scale, those of the month up to the 25th, amounting to 7027 tons. Sheet zinc is unchanged at 15c., carload lots, f.o.b. mill, 8% off for cash.

LEAD

Considerable business has been done in what the trade terms chemical lead, in contra-distinction to desilverized lead in the St. Louis district. About October 18, when the St. Louis quotation of the independents was 6.85c., large quantities of chemical lead were taken at St. Louis, with the result that all grades advanced to 6.92½c. in that territory where they have since remained. In the East, however, good brands have been obtainable at 7c., New York, the quotation to which the A. S. & R. Co. has adhered. The big interest has been quoting 6.92½c., St. Louis, for some time. In New York dealers have quoted up to 7.25c., for strictly spot metal. It is reported, and the trade is puzzled thereat, that the A. S. & R. Co. has been a buyer of lead of late. Last week a good export busi-

ness was done, largely on Canadian account. Exports from the 1st to the 25th totaled 2871 tons. The London quotation yesterday stood at £30 10s.—unchanged from a week ago.

COPPER

Rumors are current that negotiations are under way which may lead to a large sale to one of the European nations, probably Italy. No details are available at this writing, but the rumor is so generally diffused that it probably has a basis of fact. It has given the market a better undertone, though prices have not actually advanced. Spot electrolytic is quoted from 28.75 to 29c., November at 28.50c., December at 28c., January at 27.50c., first quarter at 27.25c., and first half at 27c. The producers of choice Lake are said to be sold-up until next March, for which position they quote 27.37½c. Arsenical copper is obtainable for near-by delivery at 28.50c. Practically all of the spot metal is in the hands of second-hands. The general aspect of the market is one of quiet, verging on dullness, and not much change is expected until the political situation is somewhat cleared-up. The demand for brass and copper products continues extremely heavy. Large inquiries for copper shell rings are in the market, but none of the makers can take on any more of this kind of work. If they could they could easily get orders for millions of rings. The London market is stronger at £144 for spot electrolytic, against £143 a week ago. Exports from October 1 to 25 totaled 21,681 tons. For the first nine months of the year they were 245,002 tons, compared with 186,663 tons in the same period of 1915. In this period the exports were apportioned as follows in long tons, by Secretary Mayer of the New York Metal Exchange:

	1916	1915
United Kingdom	57,454	60,458
France	118,121	68,915
Holland	2,086	947
Italy	35,405	31,415
Denmark	2,704	1,711
Norway and Sweden	8,101	12,134
Russia	18,030	9,171
China and Japan	71	108
Sundries	3,030	1,804
Total	245,002	186,663
Total exports in 1915 amounted to 276,344 tons.		

TIN

At no time since the last report has there been any great activity in the market, although in the last half of last week buying was steady, if moderate in total volume. The quotation yesterday for spot Straits was 41.25c., with spot Banca at 40.87½ to 41c. Banca has been surprisingly steady, and has held close to the quotation for Straits. Permits to ship from England are again more difficult to secure, and this has had a stiffening effect on the market here. Arrivals this month total only 2065 tons, and it is felt that the monthly statistics will show a substantial reduction in stocks. The quantity afloat is 2025 tons. In August imports of tin at Pacific ports totaled 313,902 lb., valued at \$124,329 in the San Francisco district, and 941,321 lb. valued at \$378,373 in the Washington district.

ANTIMONY

Again the market can only be reported as dull, with Oriental grades at 13 to 13.50c., duty paid. Considerable business was done on Canadian account a few days ago in metal required for shrapnel bullets. Needle antimony is quoted at 11 to 11.50 cents.

Company Reports

ORIENTAL CONSOLIDATED MINING CO.

As usual, the 36-page report of this American company operating in Korea, contains much of interest. The following notes are from the remarks of the general manager, Alf Wellhaven:

From 309,730 tons of ore treated, total receipts were \$1,636,300, equal to \$5.28 per ton. All costs amounted to \$2.91 per ton. After paying for development and construction the profit was \$677,820. Three dividends of 50c. each absorbed \$644,080.

The following table gives some details of the mines:

Name	Development, feet	Production, tons	Average value	Reserves, tons
Tabowie	13,000	126,766	\$6.73	560,000
Taracol	12,798	104,957	4.64	210,000
Chintul	4,321	25,968	1.15	20,000
Tongkol	981	7,472	7.56	7,000
Charabowie	2,636	43,723	8.17	45,000
Candlestick	2,878	1,704	7.64

The average cost of mining was \$1.79 per ton, including development. Results of exploration were satisfactory in the Tabowie, Taracol, Tongkol, and Chintul mines. The future of the Charabowie and Candlestick is not bright. On outside properties a total of 3740 ft. of prospecting was done, with poor results.

Some mill details are as under:

Name	Stamps	Ore crushed, tons	Bullion, tons	Concentrate, tons
Tabowie	80	4.59	126,766	13,856
Taracol	80	4.97	137,537	294,309
Maibong	40	3.12	43,723	2,264
Candlestick	19	3.39	1,704	9,368

Cyanide plants gave the following:

Name	Concentrate treated, tons	Value	Recovery, %
Taracol	26,281	\$66,023	85.6
Candlestick	1,704	3,648	64.6
Maibong	2,264	51,136	91.2

The total extraction in bullion and concentrate was 90.2%. Milling expenses were 47c. per ton, a decrease of 1c. Recovery at the Taracol cyanide plant was 1.7% higher and cost 1c. lower; at the Maibong tube-mill plant the recovery gained 20.3% and the cost was lowered \$1.79 per ton. Some slag bullion was included, so the 94.2% may not be maintained. Concentrate treatment cost \$1.99 per ton of concentrate, or 19c. per ton of ore. The assay-office made 41,198 determinations at a cost of 13.16c. each.

The report contains notes on construction, cordwood railways, forestry, hydro-electric power developed (130 hp.), rainfall (76.1 in.) machine-shops, transportation, bullion expense, geological examination, medical, tree bath-house for native employees, and bonus of \$10,000 for white employees.

The output to date is \$25,743,213 from 4,141,397 tons of ore, and dividends totalling \$7,069,860, or \$10.50 per share.

The crest of a single anticlinal fold of a vein is held to be a sufficient apex to sustain an extra-lateral right thereon. A terminal edge on the vein held not to be necessary in order to constitute an apex.

Jlm Butler Tonopah Mining Co. v. West End Consolidated Mining Co. (Nevada), 158 Pacific, 876, July 3, 1916.

Note: This decision was discussed fully in our issue of July 22, 1916, and has since been taken on appeal to the United States Supreme Court.

Book Reviews

HANDBOOK OF ROCK EXCAVATION METHODS AND COST. By Halbert P. Gillette. P. 825. Ill., index. Clark Book Co., Inc., New York, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$5.

The author of this volume needs no introduction to the engineering profession, for his books on 'Cost Data' and 'Cost Keeping and Management Engineering' have long been standard works. This is the first of three books which are intended to cover the subjects of rock excavation, earth excavation, and tunnels and shafts. In the book under consideration there is much descriptive matter of the machines and devices employed, especially the different types of drills, steel, and bits. The subject has been divided under the general head of machinery, drilling operations, explosives, blasting methods, loading and transporting the broken rock. The application of methods and the cost are given with concrete examples of each type of work in mines, quarries, railroad cuts, canals, trenches, and sub-aqueous excavations. Considerable space has been given to the discussion of steam, compressed-air, and other power-plants, considering the cost of installation and relative efficiency of each type. There is described such a wide range of conditions of work that the engineer can scarcely fail to find in this book data on operations closely analogous to his own individual problem. The diversity of subjects treated makes it valuable to all branches of the engineering profession. The flexible leather binding and pocket size adds convenience to its usefulness.

THE MINERAL INDUSTRY, DURING 1915. Edited by G. A. Roush. Vol. XXIV. P. 941. Ill., index. McGraw-Hill Book Co., New York, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, \$10.

While appearing a little later than usual, and considering that the War has interfered with the collection of foreign data, those who make use of this annual compilation on the statistics, technology, and trade of the world's mineral industry will find that it is as valuable as ever. Forty-eight specialists covered 55 metals and minerals. Since the conflict in Europe started and the normal condition of the world's mineral business was greatly curtailed, American prospectors, engineers, metallurgists, and ore dealers have had a busy time on account of the shortage of many products, discoveries of important minerals, finding new markets, devising treatment, selling at high prices, and settling down to new conditions. Queries on all subjects have been sent, in great numbers, to the trade, technical journals, and others, the U. S. Geological Survey receiving up to 1000 a week. The changes in conditions in each important commercial mineral or metal are recorded in the work under review. The War created an enormous demand for base metals, for export, apart from better domestic demand; on the other hand, it prevented the importation of many vital minerals that enter into manufacture of special materials. Aluminum, antimony, chromium, copper, iron and steel, lead, manganese, nickel, oils, phosphates, potash, sulphuric acid, tin, tungsten, vanadium, zinc, and others are discussed from the trade's point of view and improvements in metallurgical practice. Abstracts are given of the important articles appearing in the technical press; in fact, there is so much information that it is impossible to attempt to go into detail. Progress in ore dressing is a valuable summary. A new chapter, and one demanded by its great importance, is that of 35 pages on concentration by flotation. The previous chapter on ore dressing also contains a good deal on flotation but the two writers do not overlap to any extent. We note on page 776 and 828 similar cuts of the Anaconda mill, also a few typographical errors on other pages, though not serious. Eighty-one pages of statistics complete a useful and well-prepared book of reference.

EDITORIAL

T. A. RICKARD, Editor

PLATINUM has risen to \$100 per ounce for soft metal, the rise caused by the War being accentuated by holiday requirements. This also is a factor in improving the demand for silver.

COST of living continues to increase and is now close to the 200-mark, as against 140 a year ago. National prosperity is being heavily discounted. The rise in the price of flour and potatoes is more real to most people than the soaring of stock quotations.

EIGHTY per cent of the copper to be produced in the United States during the first half of 1917 is said to be sold in advance. This would indicate that 900 million pounds of copper has been placed for delivery during the first six months of the coming year, the refinery yield being estimated at 185 million pounds per month. At 26 cents this half-yearly output of copper would be worth \$235,000,000. Even that does not cover all the business in the metal for forward delivery, some consumers looking even farther ahead.

MILLS and machinery are capable of expanding in capacity to a remarkable degree. At the Utah Copper plant formerly rated at a capacity of 20,000 to 22,000 tons is treating 36,000 tons daily. The stimulus of high prices has increased the output of men and machinery everywhere. The Utah Copper mine is credited now with an earning of \$1,000,000 per week, including its 51% interest in the Nevada Consolidated. Speaking in millions, it is interesting to note that the Anaconda has now attained a smelter capacity of 1,000,000 pounds of copper daily. There, as elsewhere, the hurry to make the most of the favorable market is tending continually to increase the cost of production. When the War ends, there will be a big readjustment in technical methods in the effort to return to a lower basis of cost.

GOOD news comes from the Mother Lode region. The strike is over. It appears that the action of the Federal Court and the importation of men from the outside proved decisive, but the basic reason for the collapse of the strike was the recognition of the fact that there was no real reason for it, none except the usual attempt of the Western Federation to incite trouble. We note that the dividend-paying condition of two large properties was held an excuse for demanding higher wages. The men do not know how much money has to be put into a mine before it becomes profitable, nor do they know how much is spent long after dividends have been

suspended. The failure to publish statistical information on these matters furnishes the labor agitator with the chance to tell yarns and to lay stress on the temporary richness of a mine. While the operators on the Mother Lode have made money, they have made no such clean-ups as those engaged in copper mining; many of them have taken the dividends from one mine to prospect or re-open another property in the same district. Just now gold is in a depreciated condition as measured in supplies and machinery; this is no time to harrass the owners and operators of gold mines.

WE note a change in the editorial control of our London contemporary *The Mining Magazine*, the October issue appearing under the flag of Mr. Edward Walker, formerly assistant-editor. He succeeds Mr. H. Foster Bain, whose short tenure of the editorship is ended by the acceptance of an appointment in China, whither he is now sailing. We congratulate Mr. Walker and the readers of the magazine. Mr. Walker has fully deserved his promotion, for he is responsible for much of the careful work that enabled our contemporary to achieve a rapid success when it was started seven years ago. We do not even demur to the remarks made by *The Financial Times* that "in these unprecedented times it is particularly appropriate and satisfactory that the editorship of such an important publication should revert to English hands and also that a well-known and highly respected London mining journalist of purely British antecedents should have become associated with the management." The concluding clause in this quotation refers to the transfer of Mr. Edgar Rickard's interest in the *Magazine* to Mr. W. F. White, who has been honorably identified with *The Mining News*, a small but clean commentator on mining affairs in London. We wish the new management every success.

MEXICAN affairs proceed in the usual way. Now that the presidential election is over, we may expect to hear from the Joint Convention, which has been holding lengthy conversations in the salubrious air of Atlantic City. We do not expect any practical result from these debates. The Mexican position cannot be remedied by talk. Meanwhile Villa, or the substantial ghost of that villain, has been making the *de facto* Government of Mexico look foolish, if it needed his depredations to do so. By the capture of Santa Rosalia and Parral, and by his incursion upon the city of Chihuahua, he has shown what a weak hold Carranza has on the northern region. Trustworthy news is hard to get, much of it having been manufactured recently in order

to influence our presidential election. So far as we can learn, the Carranza government is making no real progress in pacifying the country or in restoring the semblance of order. Despite the political chaos our operators and engineers are returning to their mines, hoping against hope that somehow they will be enabled to work their properties even though their own Government refuses to protect them.

THIS week discussion begins with a sensible letter from Mr. Joseph Ralph, a widely-traveled engineer, who lays stress on the fact that the nomadic professional man cannot take a big load of books with him and must perforce restrict his literary baggage to a few essential handbooks. Mr. Fred. B. Ely, a mining engineer that knows the economic value of geology, discourses on geologic theories and the danger of generalizations, giving specific examples of conditions modifying the distribution of ore in the rocks. Mr. Charles F. Willis, in his capacity as Director of the Arizona Bureau of Mines, takes objection to sundry remarks of ours, for which we do not apologize, but we are glad to give him the chance to explain his position. Finally we insert a note on the use of the Hardinge ball-mill at Miami.

Base Metals After the War

Discussion concerning things that will happen "after the War" is a pleasant pastime if for no other reason than that it permits us for a while to imagine the world normal again. Whether the wish be only father to the thought or whether the sizes multiply that there is to be an end shortly to "the pentecost of calamity" we cannot affirm, but we shall talk with our readers on a matter of commercial import, namely, the effect of peace on the price of the base metals. In doing so we accept the aid of an excellent address on the subject delivered by Mr. Charles S. Trench before the recent annual convention of the National Hardware Association. Mr. Trench acknowledges that no confident prediction is possible so long as there is uncertainty concerning the duration of the War and the nature of the ultimate decision, but he argues that we can assume that when the change to peace does come the United States will face it with an overflowing pocket book, that the recent advance in the price of the metals has not been the result of speculation, that we have accumulated no surplus stocks, and that while the War lasts both our domestic consumption and the demand for metals from Europe will continue. The chief danger is that peace will find us with a production in excess both of our own requirements and those of Europe. Any abnormal level of prices is sure to undergo unpleasant adjustment, as has been already foreseen as regards antimony and spelter, both of which have dropped far from the speculative price of a few months ago, the first falling from 15 cents per pound to 9 and the second from 27 cents per pound to 24. It is generally recognized that any metal that is doomed to the last lap will be in danger of a violent collapse when hostilities

cease. But while we may all agree that the first assurance of peace will upset the metal markets, as the declarations of war did in 1914, we have yet to consider what will happen when the shock is over and the so-called civilized world faces a new set of conditions. To that we now come. The Allies have been accumulating stocks of metal, and they are likely to continue the process of accumulation, largely by purchase from us. They realize the possibility that this source of supply may be cut off either by the United States becoming a belligerent, by an interruption to trans-Atlantic transport, or by the placing of an embargo on American exportation. Should the War cease soon these stocks would menace the market. The Central powers are believed to be short of some metals, notably copper, but large purchases of that metal are reported to have been made on German account for delivery after the War. We may expect a sudden halt in the European demand unless the cessation of hostilities is treated merely as an interval preparatory to a resumption of the conflict and the replenishment of munition supplies. Turning to the specific metals, it will be well to compare prices today with those just before the War, and with the average of the 30 years before that.

	Average of 30 years before the War	1912-1913	November 1, 1916
Copper	14.06	16.00	28.50
Lead	4.25	4.44	7.00
Zinc	5.36	6.45	10.27
Tin	27.63	45.37	41.00

Tin has suffered from the War, for it is an essentially peace metal; ocean transport has been so costly as to interfere with shipments, production is not increasing, stocks are low, and the end of the War will see a rise due to the need of the metal in Europe, as well as the increasing consumption in this country. The United States produces no tin worthy of statistical mention, and it is quite possible that England may place an export duty on the tin produced in her dominions. Lead has doubled in price since October 1914, this increase stimulating our domestic production. The use of it in munitions has played an important part. The protective tariff on this metal will not help the miner, as we are producing considerably more than we consume. Therefore a decline is certain, because export trade will diminish.

Zinc has had a good time during the War, rising from 4½ to 27 cents per pound during the first year of hostilities. The high price reflected the insufficiency of supplies, caused largely by the cessation of production in Australia, due to the loss of smelting facilities when the Belgian refineries were closed and the German plants became inaccessible. The price of 10 cents today represents not so much the scarcity of metal as the increased cost of production, which is probably about 7 cents, owing to higher wages and the greater expenditure for materials. Before the War, Europe smelted twice as much spelter as the United States, and three-quarters of the European output came from Belgium and Germany. Great Britain contributed only 55,000 tons, although

that country consumed 200,000 tons per annum, this being also the amount produced in Australia. During the current year the British government has awakened to the logic of the position and has taken steps to stimulate domestic smelting, so that plants capable of producing 100,000 tons per annum are now assured. Formerly our exports of spelter were negligible, being balanced by small imports of zinc ores from Mexico and elsewhere; therefore we had no say in the world's market for spelter, which was completely under the control of the German cartel. Since the War the domestic demand has been enormous, to make brass for binding shells and for other warlike purposes. The number of retorts in blast has been nearly doubled since the end of 1914, representing an increase of production equal to 350,000 tons of spelter per annum, as against an actual output of 346,676 tons in 1913. Besides this there is the production of electrolytic zinc, which is destined to prove an important factor in regulating the price. At the end of this year there will exist the plant for producing 900,000 tons of spelter per annum. The production in the first half of 1916 was 267,696 tons from domestic ores and 50,000 tons from imported ores, mostly Australian. Exportation will not cease when the War ends, but there is bound to be a severe decline, besides a heavy shrinkage of consumption by the brass trade in this country. A complete re-organization of the spelter business is inevitable. The high cost will compel many retort-plants to close-down as soon as the price of the metal responds to the slackened demand. Many of the existing smelters can go out of business cheerfully, having paid for themselves several times over, and the survivors among the retort-smelters will have to face the competition of the higher-grade electrolytic zinc, which will dominate the market. There lies the hope of the industry, for if electrolytic zinc of 99.98 purity can be made for 4 cents or thereabouts there will be a chance for the galvanized trade to expand and for the miner to make money out of zinc even after the War.

Copper is the most important of the base metals and the one playing the greatest part in the economies of war. The outlook for this metal is cheerful. Evidently the British and French governments believe that copper will be in great demand for some time to come, otherwise they would not have contracted for 448,000,000 pounds at 26 cents for delivery in 1917. Normal consumption in the world increases 7% per annum; that in itself is a potent factor. It is true our domestic production promises to be 900,000 tons this year, as against 600,000 tons in 1913, and within a few months we shall have a refinery capacity of 1,200,000 tons per annum, but even before the War our consumption was as high as 400,000 tons, and under prosperous conditions we could now consume fully 500,000. Our export for several years before the War averaged 350,000 tons annually, of which 100,000 went to Germany. In 1913 the preparation for war caused Germany to import 153,500 tons from us. There is reason to believe that in that country all the stocks of copper have been used and that the Central powers will

be bare of the metal when peace supervenes, despite the saving and re-using of the reject from munitions. All the copper utensils, roofing, and wire that have been melted will not be replaced at once, of course, but there should be a heavy demand for our copper from that part of Europe. A decline, of course, there will be, and the first effect will be to curtail production automatically, the copper of many mines being won at a cost that will prove in excess of the market price. If the average cost of American production was 10 cents per pound before the War, it is now probably about 12 cents. Even the big low-grade properties are being worked extravagantly in order to make the most of the extraordinary market; in a sense they are being 'gutted' to make the most of an unexampled opportunity; so that when this orgy of production is over there will come the day of reckoning. Much cream will have been gathered and much blue milk will remain. But the reduction in price will be less violent than in the case of zinc or lead, because of the industrial demand for re-constructive work in Europe, including the ship-building that must follow the general resumption of peaceful traffic overseas. The drop in copper will not hurt the mining of the metal so much as it will deflate the balloon of speculation that is now being blown so assiduously by the forced production of the mines and the cheerful optimism of the brokers. There lies a real danger, as great as that of peace. And what a pitiable thing it is that Peace should be regarded as a menace to the welfare of any of us. Let us look forward to the day when our prosperity will not be built on the misery of others and the degradation of the human ideal.

The Mining Law

We note that the revision of the mining law is one of the many subjects to be discussed before the American Mining Congress at Chicago next week. On another page we publish part of a careful article on the mining regulations of various countries by Mr. William E. Colby, a distinguished Californian lawyer deeply versed in the complexities of the subject. It is a subject that will continue to vex us until either the present law is changed radically or we agree to let it alone for fear of worse. So far the attempts to introduce remedial legislation before Congress have met with disapproval even from those that insist on the necessity for sundry changes. For instance, the chairman at a recent meeting of the New York section of the Mining and Metallurgical Society of America, a technical organization that, despite its pretentiousness, has done real service to the mining public by a propaganda for the revision of the law, was constrained to say that Mr. Foster's bill "makes the situation, if possible, worse than under the present laws, and is not worth discussing." So bad are considered the various bills now before Congress for amending the mining law that Mr. W. R. Ingalls, aided by other members of the Society mentioned, has drafted a number of provisions meant to express the purpose

and desire of a group of mining engineers that has worked hard for several years to bring about some sort of reform. It is important to note that the idea of legislating for the appointment of a commission to revise the whole mining code has been abandoned by these gentlemen, who, after many consultations, have concluded that while one or two radical alterations are required it is best to change the existing regulations as little as possible, in order to retain the language of a law that has been tested and interpreted in a multitude of court decisions. This, it will be noted, is also the view urged by Mr. Falcon Joslin, an Alaskan engineer for whom we have much respect, in a letter published on another page, although he goes farther and opposes any tinkering whatever with the regulations now in force. Such of our readers as have taken the trouble to read the various articles on the subject and to attend conventions or other meetings at which the mining law has been discussed will realize that while there is a preponderance of opinion in favor of making changes, more particularly the abrogation of the extra-lateral right, nevertheless when it comes to devising a new law the enthusiasm of reform is dissipated in a dust-storm of inchoate ideas and half-baked proposals. For example, the protracted discussion before the New York section of the Mining and Metallurgical Society as printed in its bulletins gives a fair measure of the divergence of opinion even among a group of men having much in common, but if the suggestions made by these engineers were to be presented to a similar group of prospectors and small operators, people vitally affected by the law, the New York proposals would be met with howls of disapproval. For instance, the substitution of a cash payment in lieu of the \$100 worth of assessment work or the permission to locate claims without restriction of number or the locating of them along north-south lines would evoke lively objection; so would the idea of making it a misdemeanor for anybody to re-locate a claim. Behind these simpler, but important, matters there looms a number of bigger problems: the classification of the public lands into mineral and non-mineral, the right to mine on private land, the distinction between surface rights and mining rights, and the existence of State laws conflicting with any Congressional legislation. If the killing of the extra-lateral right goes with the abolition of the demand for a discovery of ore, is the locator to be allowed only a possessory title without discovery or is he to be granted a title in fee before he proves the existence of ore within his claim? If the latter proviso is to become a part of the new law, then again the Western miner will be up in arms against a reform so prejudicial to the prospector or locator without much money. The problem bristles with trouble. Such a bill as Senator Smoot's, supported as it appears to be by many of the mining engineers, because it is simple and drastic, without any effort to revise the whole system of land laws, would make confusion worse confounded. Nor have we much confidence in the provisions for a new mineral land law as outlined by the gentlemen in New York because,

whether we engineers like it or not, the formulation of laws must be done, in the last resort, by lawyers; at least, the codification of the geologists and engineers must be revised severely by men specially trained in such work before we can phrase a bill that will stand the test of the courts. Moreover, applaud as we may the public spirit of our reformer friends and sympathize as we do with their earnest desire to clear the complexities arising from the existing law, we do not believe that the changes suggested by them, in consultation with the big operators and financiers directly engaged in mining, will escape the sharp criticism and probably stalwart opposition of the men at the other end of the mining business, namely, the prospector, the day's pay miner, and the local operator, all of whom look for protection against the power of great wealth. If any change is to be made in the mining law it will have to be in a spirit similar to that prompting and underlying the first codifications of 1866 and 1872. Most engineers are accustomed to looking upon the existing law, associated with the name of Senator Stewart of Nevada, as the work of a few unscientific men, if not the production of a group of provincial lawyers. On the contrary, it embodies the experience of the mining communities in the West, primarily in California, and was based on the earlier mining traditions of Derbyshire and Cornwall, of the Hartz and Joachimsthal. It was a sublimate of human experience first in Europe and then in the new mining districts of Western America. The language of the existing law contains the words and the phrases taken from the miners' rules and regulations as adopted in scores of localities and modified during the period when the mining industry was in its vigorous infancy. The law has proved incomplete and inadequate because the wonderful variety of form assumed by ore deposits was not foreseen forty years ago, but it has been subjected to the hot fire of litigation so often and for so long that much of its refractory elements have been removed and it is today a workable body of regulations that is so well understood and so well supplemented by the decisions of the courts that the average man knows what to do in order to protect himself in his work of exploiting mineral. It appears to us therefore that the only alternative to the retention of the existing law is a total revision of the land laws of the United States. That is a task involving years of investigation by a commission of men specially qualified in the knowledge of the law and of mining. Any radical changes made now without exhaustive enquiry will entail hardship and confusion for a time, and we doubt if they are worth the price, believing that nothing short of fundamental revision will be satisfactory in the long run. We hope that our friends in New York will revert to their former idea of urging the appointment of a commission of five members, to include at least one lawyer and one representative of the Department of the Interior, besides others having experience in mining and in the acquisition of mineral lands, such a commission to be selected and appointed by the President of the United States.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

A Traveler's Library

The Editor:

Sir—If the engineer is 'traveling' on a fee with instructions to report the prospects for exploiting a mining property profitably, I would say that his sole library should consist of about 17 blank note-books and a gross of lead pencils. On the other hand, if he has inveigled someone into paying him money to take a post-graduate course in economic geology, then why stop at the index to the Transactions of the American Institute of Mining Engineers? Why not load the whole series on a pack-mule, and then utilize Dana, Lindgren, Spurr, Stretch, Pirsson, Kemp, Miller, Gunther, Kraus & Hunt, and a few others, to balance the load.

Books are media for conserving and distributing knowledge. They constitute the basis of education and are a 'loose-leaf' system for mental refreshment. But, after all, knowledge is based upon the principles postulated by Locke, to wit, perception and reflection. If an engineer has had the 'nerve' to pocket a fat fee to report upon a set of conditions coming within his supposed sphere, and relies on tabloid doses from his favorite author for inspiration in writing his 'report,' then he has missed his vocation. He should specialize as a parson or preacher, for example, for I have been informed that passable sermons can be purchased 'ready-made' to cover any conceivable topic.

Brother Spurr is good, for example. He is so good that I bought several copies to present to my attorneys, so that they could get the rudiments of physical and economic geology into their heads instead of taking their ideas on the installment plan and 'second-hand' from myself. This procedure saved me much trouble and at the same time insured to them a clarified instead of a muddled transmission of ideas. Furthermore, every engineer should have the standard works at hand for his 'brain-food,' because the whole of life's experience is but a tuition process. Any book can do no more than enable the student to think; and when Mr. Engineer goes into the field for a patron he has no time for anything else but to observe, correlate, estimate, and deduce, that is, to observe and think. The only book which might help him at that time has not yet been written; in fact the title has not been chosen, but it deals with 'How to Make Notes.' Hence the note-book and the pencil suggestion in my opening paragraph.

Knowledge is a synthesis, and its rightful application is an art. Its various elements cannot be aligned by manipulation of a slide-rule, neither can the processes

of wisdom be resolved into a system of tables. They are not transmissible or hereditary. Ability, or capacity, consists in being able to apply this psychological synthesis to new conditions and to formulate explanations for fresh phenomena. And seeing that all of our standard textbooks have spent their value when they have enabled us to think along some particular line, they are as much out of place to an engineer in the field as a 'eribbed' sermon would be to an evangelist. Of course this does not apply to a collation of formulæ, because the place for formulæ is between covers, as I hold to the theory that the only things with which to burden the memory are the multiplication table and "Thirty days has September," etc. I am particularly dogmatic upon this last point, as my own faculty in this respect is atrociously defective.

If an engineer goes into the field with any particular author or book fresh upon his mind, he is disqualified from rightly cognizing and estimating conditions, because he is likely to be looking for a condition to fit a theory instead of being technically receptive.

JOSEPH RALPH.

Salt Lake City, October 26.

On Ore Deposits

The Editor:

Sir—To generalize on the theories of ore deposition will no doubt advance our knowledge of the science and lead to valuable economic results. However, it is also productive of much harm. Indulgence in glittering generalities is too often a habit of the charlatan who wishes to impress the layman with his general and inexhaustible fund of knowledge. There is a peculiar fascination to people at a distance in phrases such as the following: "The prospect is situated in the great schist belt of Arizona which extends from Jerome to Ray and in which are found some of the greatest producing copper mines of the world." Such statements are not by any means uncommon especially in these boom times, and the circulation of them hurts the mining profession.

It would seem as though all that was necessary for one to assume the responsibility of advising the expenditure of money on mining projects is to have a natural facility for assimilating scientific expressions and the cultivation of this faculty by scattered reading of geological literature.

The cart-before-the-horse method in any branch of science does not promote progress. If we could have a

general house-cleaning in mining phraseology and get rid of some expressions like: "One man can see as far as another in the ground;" "No man can see beyond the end of his pick;" "A man is no good until he has had *n*-years of experience;" "Yellow-legged experts," etc., there would be a real chance for placing the mining profession on a dignified basis. Any number of academic degrees will not put an engineer beyond the reach of criticism but a proper mental attitude and feeling of respect among the men in the different branches of mining will do a great deal for the profession.

It appears that we are drifting away from the main argument. Your attention was called to glittering generalities as applied to geological theories. This also might be called the cart-before-the-horse method, which requires no laborious study of surface geology and underground conditions. All that is necessary is to allow the mind to "summon up the remembrance of things past" and build up a beautiful theory (with the aid of U. S. G. S. reports), then with a few alterations here and there (after a trip to the prospect) fit the theory to the ground. It makes excellent reading and if placed in the hands of the right people is sure to gain financial support.

To generalize in any science is to employ legitimate and correct methods for advancing that particular science. Also it is certainly proper to use a goodly supply of imagination. As Professor Daly says, "Geology is an exact science in the sense that a countless number of its observations are quantitative, with limits of error so small as to permit absolutely rigorous deductions." And again, "What Geology needs today is a frank recognition that imaginative thought is not dangerous to science but is the life blood of science." Obviously we must first stand on the solid ground of facts in so far as they can be observed and then build our theories from these facts. In addition to this the mining geologist must continually adjust his theories to harmonize with economic conditions.

It is indeed a pleasure to read articles such as Probert's 'Surficial Indications of Copper,' appearing recently in the pages of your paper. This kind of generalization is bound to advance the science of mining geology. Considering the amount of high-class scientific literature available it is regrettable that more of this work is not done. Consider Arizona as an illustration. Almost every mining district is described by a competent person, still it is extremely difficult to correlate the mass of data. Some of the publications are out of print or else are difficult to obtain and only a few libraries contain a complete list. Therefore, only a few men have the time and means to dig up this information and put it in compact form. Two of the most useful books we have are Lindgren's 'Mineral Deposits' and Wood's 'Copper Mines of the World,' but these books cover too wide a field to be entirely satisfactory.

It is interesting to speculate on the value of certain

general deductions that would naturally arise from such a correlation of material, for instance, in Arizona. It could probably be shown that there are well defined and definite mineralogical provinces each one of which has characteristics peculiar to itself and related to rock associations of definite geological age and kind. It is evident that a study of any one mine in each mineralogical province would give a basis upon which to determine the relative value of a given prospect. This would be a scientific basis upon which to generalize, besides being a valuable contribution to our general knowledge of mineral deposits.

It is not safe to generalize on the similarity of types. For example, the Paleozoic sediments are represented in widely separated areas in Arizona, but in almost each locality there are fundamental differences in structure and rock association. Therefore, the fact that a copper deposit occurs in Devonian and Carboniferous limestone near to, or associated with, acid intrusives is of no value as a general statement in spite of the fact that it is so often used as a favorable feature in exploiting prospects. To illustrate: The Bisbee deposits occur in Paleozoic limestone cut by intrusions of granitic porphyry. The copper deposits occur in the limestone and appear as irregular or rudely tabular masses, sometimes following the stratification. They are almost entirely oxidized, even down to depths of 1400 ft. below the surface. A large proportion of the total copper produced comes from the enriched chalcocite ores. Another prominent feature of these deposits is the close relation to structural conditions, such as the northwest-southeast Dividend fault, a small stock of granite-porphry intruded on the line of the fault, an open synclinal structure in the down-faulted Paleozoic beds, which is such that they dip in part toward the porphyry stock and in conjunction with the fault-plane form a trough pitching southeast. These deposits are classed as contact-metamorphic replacements in limestone. It is well known that this type of deposit occurs in a number of localities in Arizona. However, it is apparent that as a guide to prospecting or in fact as a basis for speculating on a particular district, even though there is evidence of mineralization in limestone in the vicinity of acid intrusions, the analogy is of little value. It is only by carrying the comparison down to minute details that we can make any really scientific deductions.

At Duenesne, also in Arizona, the ore occurs as a replacement in limestone mainly in or near the metamorphic zone along the limestone and quartz-monzonite contact. However, in contrast to Bisbee: (1) There is very little oxidation. (2) The ore as mined consists almost entirely of primary complex sulphides. (3) Thus far the profitable ore has not been found to extend to any great depth. The ore on the 500-ft. level of the Bonanza mine being low grade and the bodies irregular and small. (4) The metallization is not related to any strong or persistent faulting. There is however, a marked jointing and fissuring, which possibly has a direct bearing on the ore occurrence.

At Twin Buttes, south of Tucson, large bodies of primary ore occur below a garnetized bed containing but little copper. The ore consists of actinolite, magnetite, pyrite, and chalcopyrite. It is a replacement deposit in Paleozoic limestone at or near the contact of granite-porphry.

It will be observed that in the three localities cited, there are copper deposits occurring in Paleozoic limestone associated with acid intrusions, but in each case there are fundamental differences that must prevent any generalization of practical value. However, each district should be considered as a distinct mineralogical province and the boundaries for each district definitely ascertained in so far as it is possible from geological studies. When this has been done any group of people wishing to spend money on a prospect in any one of these districts would have scientific data of inestimable value.

This line of study applied to the State as a whole would permit of a number of valuable deductions, which would doubtless show similarities in certain localities. With such information it would be logical and scientific to form generalizations that would help in prospecting a new or partly developed property. It is surprising that Arizona has not a competent State Geologist to carry on this work, supplementing the special studies of individual mining districts by the U. S. Geological Survey.

FRED. B. ELY.

Superior, Arizona, October 28.

Arizona Bureau of Mines

The Editor:

Sir—I note on your first editorial page a very complete 'bawling out' for the Arizona State Bureau of Mines, and would suggest that your reader of press-letters read them a little more carefully. On the press-letter to which you refer, you quote us, and we quoted the *Mohave Daily Miner*. If you will notice where the quotation marks stop, you will note that only the last paragraph of the press-letter came from the Arizona State Bureau of Mines.

You will also note in the last paragraph, the only one which we wrote, that we have issued a booklet on the subject of the selling of copper, which booklet takes precisely the opposite view from that of the *Mohave Daily Miner*. I am sending you a copy of the booklet.

Probably one of the most important parts of our work is to secure co-operation and good feeling between the large and small operators in the State, and between the laboring man and the mine operators, and your editorial, which will be read by many of the operators and misinterpreted by them as you misinterpreted us, will do us much harm. We quoted the *Daily Miner* in order to get the people of the State to send for our bulletin, which goes into much more detail than a press-letter could. I wish to assure you that we do not in any way agree with the *Daily Miner*.

I am sending you an additional copy of the press let-

ter, and a copy of our Bulletin No. 36. I sincerely hope that you will make an effort to set us right.

CHARLES F. WILLIS,

Tucson, October 30.

Director.

[The press-letter came under the heading of 'Arizona State Bureau of Mines.' In this circular the quotation marks were used confusingly, being attached, within the quotation, to the word "independent" at the beginning of the second paragraph. The press-letter contained 38 lines from the *Mohave Daily Miner* and only 7 of the Director's own comment, in the course of which he expressed no criticism or disagreement with the long quotation preceding. We inferred, as any other careful reader of the press-letter would have done, that the Director of the Bureau endorsed the Mohave paper; if he did not, he should have said so; to quote another man at length without criticism is usually deemed a mark of approval.—EDITOR.]

Hardinge Mill at Inspiration

We have received the following telegram from Mr. H. W. Hardinge:

On page 636 your report regarding trial of Hardinge ball-mill at Inspiration reverses the statement made and should read the Hardinge mill did not receive a trial as a ball-mill. The report as published by you is an injustice to the Inspiration management the metallurgical fraternity and my company and places an authenticated misstatement in the hands of our competitors. The only competitive Hardinge ball-mills for the Inspiration company are now en route for Miami. The circumstances justify your correcting the mistake far as possible.

This refers to a statement made by Mr. David Cole, in a discussion on flotation in the course of which he dismissed the experiments made with various grinding machines. He states that only the Hardinge pebble-mill was tested and the inference is clear that the Hardinge ball-mill did *not* undergo trial at the time to which he refers, although we understand that since then the work done in the Miami mill has indicated that the Hardinge ball-mill is most effective, hence the sending of similar machines now to the Inspiration. On comparing Mr. Cole's final statement with what he had previously said, it is clear that a typographical error was made in the stenographic record of his remarks and that this error was inadvertently repeated by us. The statement should read: "Contrary to what I think is the popular impression, the conical type of ball-mill did *not* receive a trial at the Inspiration." In the same report of the Institute meeting, Dr. Gahl's reference to Mr. Laist's remarks should have read—so he informs us: "I believe fully everything that Mr. Laist says, except his compliments," *not* "conclusions." These gentlemen were on the most friendly terms, and not sparring, as the report might suggest. We obtained a revised version of his remarks from Dr. Gahl, but this detail was not corrected.

AN EIGHT-HOUR LAW for all employees has been passed in Ecuador, South America.

Revision of the Mining Law

By courtesy of Mr. Falcon Joslin we are enabled to publish a copy of his letter to the Chairman of the Committee on Mines.

Fairbanks, October 9, 1916.

Hon. M. D. Foster, Chairman Committee on Mines,
House Representatives, Washington, D. C.

Dear Sir: I have your circular letter of March 25 enclosing copy of H. R. 12275 relating to the revision of the metal-mining laws. I note that you invite criticism.

I am very firmly against any revision of the mining laws. I know there are many excellent men who advocate a revision and some of them are my friends, but I cannot agree with them. I think they are mistaken.

The existing law is the growth of years. It began with a skeleton law passed in 1866. It was extensively amended in 1872. In the forty years and more since then it has been interpreted by the courts in thousands of decisions and amended many times by Congress and by the local legislatures. Defects revealed by time or by the decisions have been dealt with as they appeared. In this respect the growth of the mining law has not been different from the growth of our constitution, our banking laws, or indeed any of our laws. All laws are the result of such growth. They are never made perfect and complete. Perfect mining laws are only an ideal which can never be attained. Many of those who now so eagerly advocate revision are thinking of perfection and forget the difficulties of its attainment.

Our mining law has some defects but not nearly as many as some would claim. It is a liberal law and one of the best in the world.

It is familiar to the prospectors and mining people and nearly all its provisions have had judicial interpretation. It is therefore definite and certain; if subjected to any changes, they will have to go through a long process of litigation before it will be as definite as the law now is. I say "any change," for practically every word and phrase must be tested by lawsuits sooner or later. It will take forty years of litigation to produce the certainty under the new revision that we have now. This would be so even if the revision were drawn by experts and passed as drawn. But our law-making machinery is more imperfect than the law. Congress is sure to turn out a botched up measure at best as full of defects as the present law. A Commission of experts might prepare an excellent Bill, but I venture to say its authors would not recognize it by the time it got through the first committee. By the time it left the Conference Committee it would be a conglomerate of farm-land law, conservation, labor-unionism, politics, and demagoguery that would drive the mining population to despair. Then would follow the long period of litigation and amendment. In my humble judgment we had better bear the ills we have.

In Alaska we have had some sad experience with revisions. There was a good coal land law, but the restless uplifters thought we could get a much better one. The

people in Alaska did not request it. They proposed to force it on us whether we liked it or not. And they did. The result is that our old law is repealed and we have an abortion of a coal-land leasing law wholly unworkable. We need coal up here. It is a cold country, but we can't get it, though we have been trying for twenty years.

The same thing with reference to the oil law. The placer law was not exactly designed for the development of the oilfields but it worked. I think it worked well. But up here they propose to revise it. In order to make sure it should be revised, they abrogated the existing law without substituting any other. So we have no oil-land law in Alaska at all. The revisers are busy and have been for six or seven years revising the oil laws; during all this time we have had no oil law at all. When their revised oil law is passed, if it ever is, it will probably be as unworkable as the coal law. They say it is progressive legislation. We think it is medieval, for it proposes to return to the feudal system of the dark ages; The Government, the landlord, and the citizens as tenants. We have had too much experience of revision to favor any more of it. With the prevailing sentiment in favor of conservation and restriction any new law would probably be far less liberal than the existing law. The draft you send proves this.

It contains restriction after restriction. It even threatens the poor devil of a prospector with criminal prosecution if he locates a claim without pure intentions. See Sec. 2346j. The number of claims a man may locate or even hold is limited to five quartz claims or one placer claim. The present law permits a man to locate or hold as many claims as he wants as long as he does the amount of work on each required by law. This is sensible and right. There might be more labor required to hold a claim, but there is no sense whatever in otherwise limiting the number one may locate or hold. I will not attempt to discuss other details of the Bill. I am against the whole project of a general revision. There is one feature of the Bill however which I favor. That is the provision for the appeal from the decision of the Land Office to the Courts in matters arising between the Government and the citizen.

The Land Department has committed some of the most highhanded and tyrannous doings in the administration of our coal and oil lands. The acts were oppressive and illegal, but by the present law a citizen has no redress even from the most shameful and flagrant conduct of the executive departments. If there had been the right of appeal from the decision of the executive departments to the courts our coal lands would not have been tied up for twenty years as they have been. In this amazing revision of the coal-land law for Alaska it is expressly and cunningly provided that a citizen wronged by the decisions of the Land Department shall not have the right of appeal to the courts. The revisers were afraid to have their doings reviewed by the courts and we American citizens must submit to that outrage. I certainly would favor these sections if they could be passed as a separate Act.

FALCON JOSLIN.

THE STEAMER 'AMUR' LOADING CONCENTRATE AT THE BRITANNIA WHARF.

The Britannia Mine and Mill

By T. A. Richard

During August I availed myself of an opportunity to visit the biggest copper mine in the British empire: the Britannia, on Howe sound, near Vancouver, British Columbia.

This is not a fresh discovery, nor is it a new enterprise. Like many other successful undertakings it was built on the stepping-stones of earlier failures. The first finding of copper in the district was reported in 1888, but no work was done until ten years later when Oliver Furry stumbled upon the same outcrop, a bluff of copper-bearing schist on the Jane claim, which he located. Several other claims were staked and a number of samples, averaging 7% copper, were taken.* Furry interested F. Turner, of Vancouver, and Leo Boscowitz, of Victoria, in the prospect. A trail was made and a camp was established; an adit also was started and driven for 150 ft., but, failing to cut ore, it was discontinued. Work was stopped. In February 1900, nearly two years later, Joseph Adams inspected the prospect and reported enthusiastically to H. C. Walters. The latter had just made some money out of a deal involving the Snowshoe mine, near Libby, Montana, and came at once to Vancouver, going thence to the Britannia, where he joined Adams in making a further investigation. The result was the organization of the Britannia Syndicate, which purchased seven-tenths of the Turner and Boscowitz hold-

ings for \$35,000. H. L. Van Wyck became superintendent. Another large outcrop was discovered on the Fairview claim and some development work was done.

The syndicate put the property on the market. In 1901 an examination was made by W. Yolen Williams, consulting engineer to the Granby Consolidated, but no business resulted. Walters went to London and aroused the interest of a capitalist named Valentine, who took a bond on the property for \$750,000 and made two payments of \$5000 per month before he had the mine examined by J. D. Kendall, who reported favorably. Then Valentine died and his executors relinquished the bond. Mr. Kendall's report, dated April 11, 1901, speaks of the 'ore-zone' as "over 100 ft. wide in one part and more than 2000 ft. in length." He estimated the ore 'in sight'—a term now taboo—at 850,000 tons assaying 0.083 oz. in gold and 0.19 oz. silver per ton, with 2.16% copper. He suggested the use of the Elmore bulk-oil process, believing that this would save 11.6% more than ordinary concentration by water. He estimated the cost of mining at 95 cents and that of milling at 50 cents per ton. Later knowledge indicates that Mr. Kendall's estimate of the average contents of the ore was correct; his forecast of cost is confirmed; and his suggestion to use the flotation process has been put into effect, although at the date of his report the radical changes to be made in Elmore's process were too far in the future to be anticipated by him, or anybody else. Mr. Kendall may well be proud of the report he made on the Britannia mine 15 years ago. That the report failed to stimu-

*For data concerning the history of the mine I am indebted largely to 'The Copper Handbook,' by the late Horace J. Stevens, and to an excellent article by E. A. Haggren in the *Mining, Engineering and Electrical Record* of August 1915.

late the exploitation of the deposit was due to the almanac: in 1901 the economic value of 2% copper ore was not understood.

Another start was made at the end of 1901, when George H. Robinson, an engineer of high rank, associated with important mining operations in Montana and Utah, bought the controlling interest in the Britannia Syndicate, on a report by James W. Neill, at a price of \$400,000. Evidently the syndicate made a reasonable profit. Later Robinson bought the three-tenths held by Turner and Boscowitz for \$53,000. He organized a new company called the Britannia Copper Syndicate, with the late Edgar E. Dewdney as president and himself as managing director. Another director was H. C. Bellinger. The capitalization was \$937,500 and the new stock was underwritten by Henry Stern, who had the financial aid of Grant B. Schley, of the firm of Moore & Schley, in the flotation of the issue.

Robinson started to develop and equip the mine systematically. An aerial tramway was erected, a concentrating mill was built, and new adits were started. The ore and concentrate were shipped to a smelter at Crofton, on the opposite coast of Vancouver island, 60 miles west. This plant included two blast-furnaces and one converter-stand, producing blister copper that was sent to Chrome, New Jersey, for electrolytic refining. A briquetting plant was used to prepare the copper concentrate for blast-furnace treatment. This smelter had been operated by the Southwestern Smelting & Refining Co., a local enterprise operating a copper mine on Mt. Sicker. In 1905 the Britannia Smelting Co., with a capital of \$625,000, acquired this metallurgical plant together with the Mt. Andrew mine on Prince of Wales island. But the Crofton smelter was not a success; it was closed down in 1910, and has been dismantled, the useful portions of the equipment being transferred to the Britannia mine. When Robinson died, in 1905, he was succeeded, as manager, by M. T. Adams.

In 1908 the Britannia Mining & Smelting Co. was organized with a capital of \$2,500,000, absorbing both the Copper Syndicate and the Smelting Company of the same name. At this time Mr. Schley came into personal control of the enterprise and R. H. Leach was appointed manager with H. C. Bellinger as consulting engineer. But Horace J. Stevens said truly and gently in 1909, "The Britannia to date has proven somewhat disappointing." This qualified statement was correct at that time; it was not until nearly five years later that the mine, then 14 years of age, began to give signs of real vitality. In 1912 Mr. Schley placed J. W. D. Moodie in charge and under his management the enterprise has been developed to fruition. The method of milling has been changed, a new mill has been built, also an incline tramway capable of transporting a large tonnage of ore, vigorous exploration has uncovered ever increasing ore-reserves, and the property has been enlarged from 1500 acres to 20,000 acres. However, the resources of a mine are not measured in acreage; the comparison simply serves to indicate that exploratory work has proved the extension of the ore-bearing belt for miles and furnished

the basis for large-scale operations of a most successful and systematic kind, under the direction of two men, a sagacious financier and a capable engineer.

In an earlier article I have described the short voyage from Vancouver to Britannia Beach, as the settlement on the shore of Howe sound is called. The distance by water is 30 miles; overland from North Vancouver it is about 22 miles; eventually the coast railway, now terminating at Horse-Shoe bay, just around the corner into Howe sound, will be extended to Britannia Beach, but the present method of transport by water is convenient and cheap.

On landing the visitor finds a clean and well organized settlement. The population on the beach, near the mill, is 1000; on the hill, near the mine, it is 800 more. The pay-roll shows 1225 employees, of 20 different nationalities. The company maintains a four-story, 60 by 132 ft., department store in which an abundant variety of supplies is displayed. Construction work is still in progress and will continue for many years, as the mine and mill grow in size. Three mill-buildings are to be seen; first, the old zinc-concentrating plant, built in 1908, which was never operated; second, the concentrator, remodeled in 1912, enlarging its capacity from 500 tons to 850 tons daily, using both water and oil concentration; third, the new mill of 2500-ton capacity, begun in 1913, employing the old and new processes in sequel.

Let us visit this new mill, which is built on a side-hill site, in six floors, having a total height of 191 ft., or 216 ft. to the top of the receiving-bins. Of the four units into which this plant is divided, three were in gear on August 27, treating 1700 tons daily. The mill-crew numbers 83 men, of whom 25 are Japanese. The building is airy, light, and spacious. The floor-space is ample, facilitating alterations. The walls are white-washed. The frame and housing are made of wood, on concrete foundations resting in solid rock. Each section of the mill has two angle-bottom ore-bins each of 500 tons capacity, so that the two sections already built have a storage capacity of 2000 tons. In addition, a stock-pile is maintained on the side-hill giving 25,000 tons more in reserve. This is fed by the aerial tramway, built originally for the old mill, and passing to one side of the new mill, so as to permit the accumulation of ore on a rocky platform cut into the ground just above the bins. The stock-pile is drawn onto a belt-conveyor that delivers into the mill bins. In front of these passes a chain-bucket sampler. Three 12 by 24-in. plunger feeders deliver the ore (broken at the mine to 3½-in. ring) to three 4 by 8 ft. trommels having 1½-in. round holes. My description will now concern itself with one unit of the mill, the other being an exact duplicate. The undersize from the trommel goes direct to the coarse rolls, the oversize to two picking-belts.

Here the ore can be examined. It consists of copper pyrite in chloritic schist. The ore picked from the belt

3A composite analysis of the mill-feed in September showed 2.74% copper, 7.95% iron, 1.5% zinc, 6% sulphur, and 71.25% silica, besides a trace of gold and 25 cents worth of silver per ton.

contains from 10 to 18% copper and represents about one-tenth of the entire mill output, which averages 15 to 16% as shipped, ore and concentrate, to the smelter at Tacoma. The ore is of medium hardness and breaks readily, loosening the chalcopyrite; it is of simple type; with the chalcopyrite there is twice as much iron pyrite, besides a little zinc-blende and galena. Associated with these sulphides is quartz.† The proportion of picked ore varies in accordance with the smelter requirement of silicious material.

Two men work at each picking-belt; they remove the

after passing through the sampler, goes direct to the bins, where it is allowed to drain before being shipped. The middling from the tables goes to a 7 by 10-in. bucket-elevator for re-treatment by one of the tables. The tailing from these runs to a two-compartment dewatering tank, the overflow from which is delivered to the final slime-tanks. The sediment from the dewatering tank is used as part of the feed to the tube-mills.

The tailing from the jigs is fed to the 'fine' rolls; the middling goes in close circuit back to the jigs; while the concentrate is transferred to the shipment-bins.

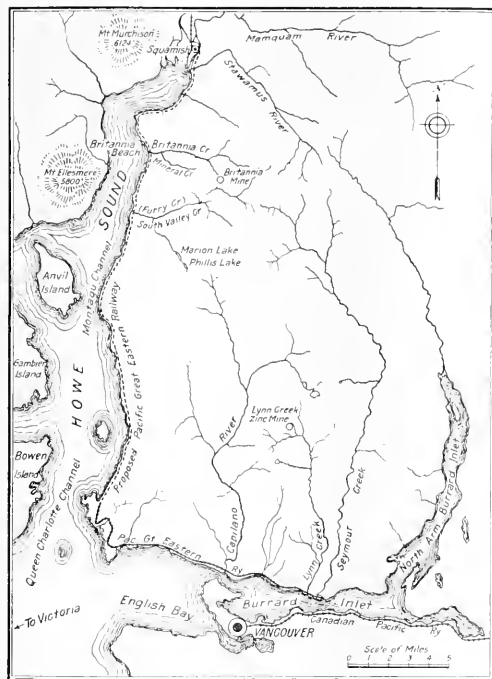

The oversize and undersize of the first set of trommels unite at the 'coarse' rolls.

The jig-tailing goes to the four 'fine' rolls, as already stated; these rolls are 36 by 15 in., style A, Allis-Chalmers, crushing from $\frac{1}{4}$ inch to 2 mm. and delivering to eight tube-mills or 'granulators,' each 7 by 12 ft. and direct-driven by a 100-hp. slip-ring motor. These tube-mills are given a retarded discharge by means of a back-worm. The lining is made of rail-sections (5 in. long) set on end in neat cement, with short pieces of worn-out drill-steel in the interstices. This affords excellent service; it is called the 'Britannia' lining and deserves to be well-known. The secret of the success of this lining is that the neat cement is placed on the smooth clean surface of the tube-mill, and in this cement are imbedded the ends of the rails, grouting them with more neat cement as the tube is turned gradually until a half-circuit has been made, by which time (three to five days) the cement has set so firmly that the rails do not fall out. The grinding-stones, selected from the picking-belts, as we have seen, are delivered through chutes in the bed-rock under the mill and taken by a belt-conveyor to a bin on the tube-mill floor, where they are fed into a bucket hung on a rail and pushed by hand. These grinding-stones, or 'pebbles,' are fed by hand into the discharge end of the tube. At the feed end there is a three-spout feeder. The discharge from the tube-mills goes to the boot of a 72-ft. elevator with 16-in. buckets that deliver to three hydraulic classifiers, the overflow from which passes to the flotation machines while the oversize is returned to the tube-mills.

The various products of the mill are divided thus:

	Proportion %	Copper content %
Picked ore	10	10 to 18
Jig concentrate	25	16 to 17
Table concentrate	25	14 to 15
Flotation concentrate	40	14 to 15

The flotation plant consists of two Minerals Separation machines of the blade-impeller type, each divided into 14 cells, operated by a 250-hp. Pelton wheel. In this mill the impeller or agitator makes 180 r.p.m.; in the old mill, 215 r.p.m. The oil is introduced as a continuous thin stream into the feed-launders. The quantity used is 42 gal. per 1000 tons of ore, a British gallon weighing 9 $\frac{1}{2}$ lb., so the consumption is equal to $\frac{2}{3}$ pound per ton of ore. The oil now being used is pine-oil, the variety known as No. 350 made by the Pensacola Tar & Turpentine Co. in Florida. Recent experiments with fir-oil, a

MAP SHOWING POSITION OF THE BRITANNIA MINE.

pieces of high-grade ore to one side and also select hard pieces of country-rock for use as grinders in the tube-mills. A chute for waste is available, but it is not in use now. The picking-belt delivers to three 10 by 20-in. Blake jaw-crushers, which reduce the ore to 2-in. size before passing it to two 16 by 48-in. extra-heavy spring-rolls. The product from these goes to three 15 by 40-in. Anaconda type of spring-rolls. The first set of rolls reduces from 2 to $\frac{1}{2}$ inch, and the next to $\frac{1}{4}$ -in. size. These deliver to five trommels, 3 by 6 ft., having $\frac{1}{4}$ -in. holes, the oversize passing to two 10-in. bucket-elevators that return this product to the second set of rolls, while the undersize from the trommels is delivered to five 3 by 6-ft. trommels with 1.5 mm. screen. The oversize from these is passed to two 14-in. bucket-elevators, which feed two Hancock jigs, while the undersize from the last trommels goes to five tables of the Overstrom type with plain riffles lengthwise. The concentrate from the tables,

product from the distillation of Douglas fir, by use of the Cottrell process, has been tried successfully. No acid is used. Out of the 14 cells, four are used for making a concentrate and the other ten for re-treating or cleaning. In the lower ten cells the froth is drab in color, dense in texture, and well pitted with the breaking bubbles. When discharging over the edge by impulsion of the scrapers it shows blotches of foam, the lighter tint of which is due to the silicious gangue. In the upper cells the froth is more uniform in texture, it shows dark greenish-gray where the scraper sends it over the edge. A revolving scraper moves the froth forward in the re-treatment or 'cleaning' cells. A trowel-scraper extends over the entire surface of the outer frothing-cell.

The aromatic smell of the pine-oil is strong in the mill, but this smell is not detectable when rubbing the concentrate between the fingers nor does the concentrate show any oily streak. The tailing discharge, on the beach, gives forth a strong smell of pine-oil, suggesting that some of it is dissolved by the water.

On the day of my visit the flotation record showed:

	Copper %
Feed	1.90
Concentrate	14.0
Tailing	0.12

The concentrate contained 26.8% iron and 20.8% silica. This concentrate goes directly to a drag-elevator that delivers it to the shipment-bins. The moisture in the concentrate is fully 20% and is reduced by draining to 8% before being loaded on board ship. The smelter at Tacoma draws the line at 10% moisture. Two 50 by 14-ft. Dorr thickeners are being erected to take the overflow from the slime-tanks, the sediment to be returned for treatment in the flotation machines, while the overflow empties into the tailing-launders.

Experience has shown that the poorer the feed the better the recovery, so that a point is reached where the flotation machine loses in relative efficiency; hence the picking-belts, the jigs, and tables. There is also the question of royalty, into which I shall not go, although local gossip is alive with interesting stories.

Between the shipment-bins there are tanks that receive the overflow from the concentrate, the sediment accumulated from this overflow going to the flotation machines, while the rest of the overflow passes to the Dorr thickeners.

By way of comment it may be suggested that the chloritic character of the schist serves to explain the ease with which the chalcopyrite is detached and concentrated. The only chemical or nostrum used is the oil. No acid is needed; it may be that the slight oxidation of the pyrite is accelerated by friction during the crushing of the ore sufficiently to produce enough sulphate to furnish acidity automatically. The proportion of iron to silica in the concentrate makes a self-fluxing mixture and suggests that the degree of concentration is determined, or might well be determined, by friendly consultation with the smelter management. The smelter allows a minimum payment of 25c. per ton on the gold

and \$20 per ounce on all above 0.03 oz. per ton. For silver 95% of the market price on the day of arrival at Tacoma is paid. The concentrate averages 0.0225 oz. gold, 1.65 oz. silver, and 15% copper. The recovery on August 28, as indicated, was 94%; it is said to average 95%, while the extraction over all, after smelting of the concentrate, is 93% of the copper in the ore as recovered from the mine. This is splendid work, of course. The cost of hydro-electric power is \$10 per hp.-year, allowing 10% for depreciation of plant. The cost of milling is 56 cents, but this it is expected to reduce to 30 cents when the plant is completed. The cost of transport to the smelter is 66c. per ton dry. For the removal of the mill-products, a tunnel has been driven through the rock beneath both mills. This is ingenious and convenient.

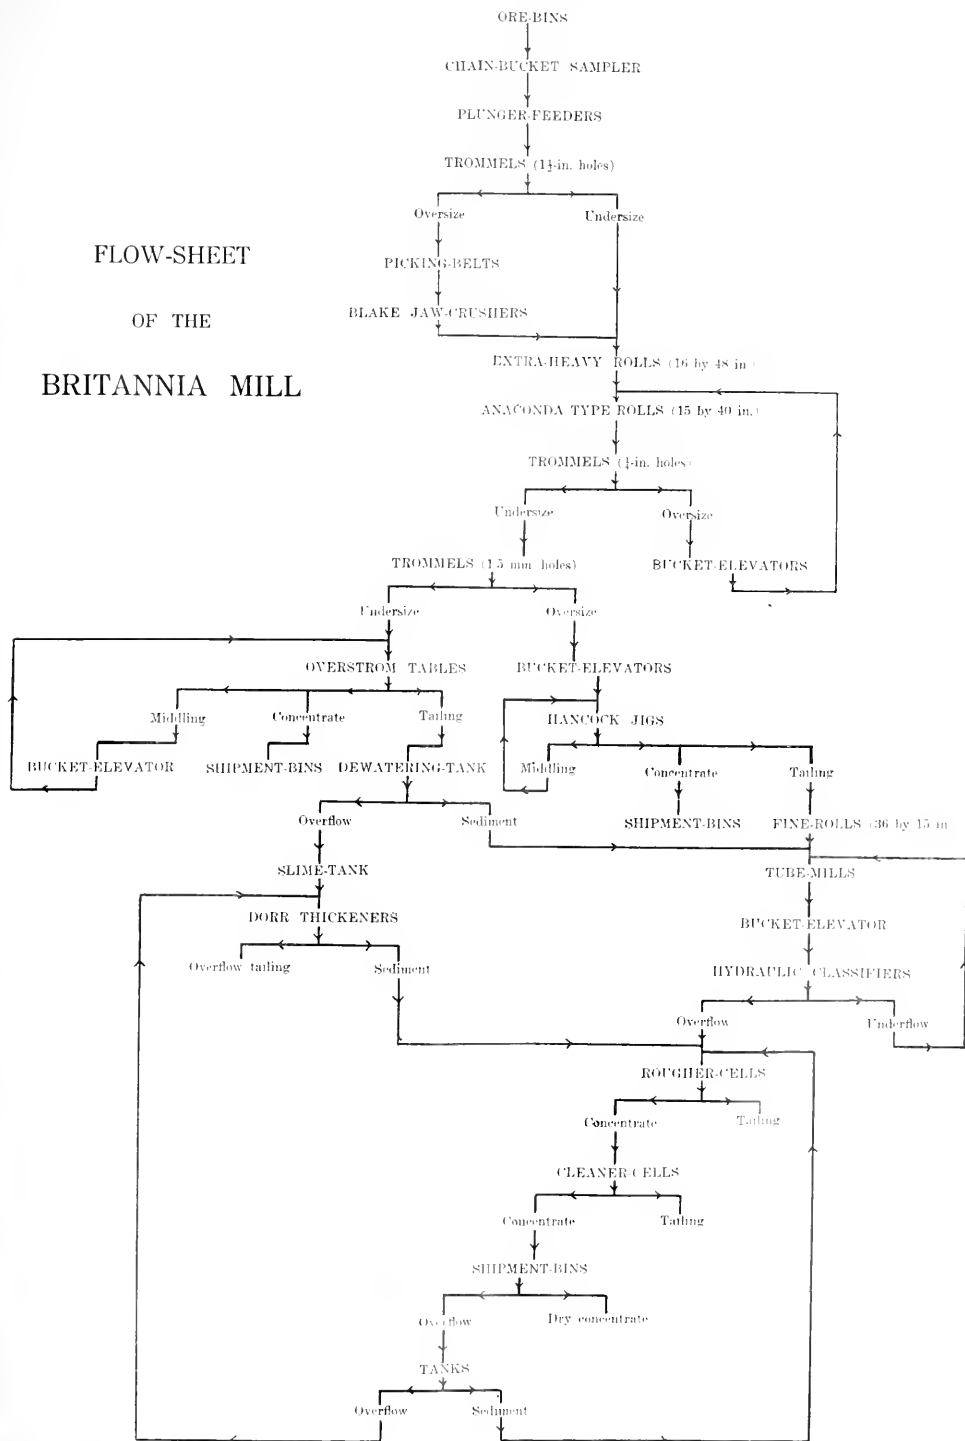

The magnetic zinc-concentrating mill, with its McDougall roaster, stands between the manager's house and the old vanner building. This plant was never started, having been recognized as useless, and is now being dismantled. One part, the old Jane workings, of the mine contained zinky ore with enough gold and silver to prompt the attempt to separate the zinc and precious metals from the copper.

On the day following my visit to the mill I was taken by C. P. Browning (Columbia, class of '13), the general superintendent, to the mine on the mountain, which rises to a height of 4300 ft. above the water.

While waiting for the car at the mill-terminal of the incline-tramway I had a look over the settlement outspread on the beach below; the little houses with their red or green roofs; the big department store and office-buildings, and beyond them the wharf projecting into the calm waters of the inlet, its rim marked by the white line of high water, where the rock is bared and bleached; the boats and their reflections; the successive headlands; the high cliffs and wooded hills culminating far away in the snowfields of Mt. Sir Roderick, named after one of the worthies of geology, Sir Roderick Murchison. Across the sound a paper-mill had the look of a chateau and recalled memories of the Dauphiné that were broken by the dumping of 20 tons of ore, the noise of which reverberates among the hills.

Sitting in front of an open-front skip, which weighed 13 tons when empty, we ascended the incline. The grade is undulating; it averages 30%, with a maximum of 33% and a minimum of 12%. The road-bed, 5500 ft. long, is 18 ft. wide and is laid with two standard-gauge (4 ft. 8½ in.) tracks of 56-lb. rail, passing through several cuts, as much as 55 ft. deep. The absence of trestles, except at the terminals, gives the tramway a solidity that is enhanced by the method of anchorage. The top of each rail is anchored to the tie by two ¾-in. slots cut in the bottom of the rail, to receive the spikes holding the rail to the ties. These are securely imbedded, thus enabling each length of rail to expand and contract independently of the track as a whole. To further this result, special attention was given to the tightening of the fish-plates and the spacing between rail-ends, with proper regard for the temperature at the time of laying. At intervals

FLOW-SHEET OF THE BRITANNIA MILL

of 1000 ft. firm anchorages were made in solid rock under the road-bed; to these were attached turn-buckles connected to the base of the four rails, so that, in the event of the track being pushed down-hill, the creep would be arrested by these extraordinarily strong anchorages. The wisdom of this precaution has been proved, no downward movement of the track having taken place.

From the car we could see the water-line descending the mountain. This consists of 7800 ft. of 36-inch wood-stave pipe reduced to 30 and 28 inches successively, then 3700 ft. of 28 and 26-in. steel pipe, delivering to two 20-in. pipes, 3150 ft. long, reducing to 18 inches. Thus the total length is 14,650 ft. The cost of flanges under a head of over 1000 ft. would be excessive if a single line of pipe were used with thread and couple; therefore the double pipe. The wooden stave is used up to a head of 500 feet.

The cable of the tramway is $1\frac{1}{2}$ inches of plough-steel. The skip has a false bottom of wood two inches thick enclosed in $\frac{5}{16}$ -inch steel plate. The wooden filler acts as a cushion. Each side of the skip consists of two steel plates. The loading-bins at the upper terminal have a capacity of 3000 tons. The engineer in charge of the lowering-engine is placed in an upper chamber above the concrete arch covering the machinery, so that while he cannot see the mechanism he has an uninterrupted view of the incline. The loading-bins of this tramway-terminal are fed by an electric train running on a track of 3-ft. gauge laid with 45-lb. rail and $3\frac{1}{2}$ miles long. The maximum gradient is 3% and the difference of elevation between the terminal points is 500 ft. A 15-ton electric locomotive pulls 4 cars, each of 20-ton capacity. These are U-shaped; the whole bottom is on end-rollers so that the car tips sideways. A tight bottom is necessary to prevent leakage of the fine, which is the richest portion of the ore.

The joint tramway and railroad terminal is level with Adit 27, so-called because it is 2700 ft. below the summit of the mountain. This will become eventually the base entry of the mine. Behind the mill is the entry of Adit 41, similarly 4100 ft. below datum. This adit will become the base exit for ore, it is only 1100 ft. long as yet, but it will be extended three miles to the ore-belt and at a mile from daylight it will connect by a raise, or shaft, with the upper adits, called 31, 27, and the present main entry, called The Tunnel, which is 1900 ft. above 41 and 2100 ft. above sea-level. The sizes of these new adits are

41	9 by 13 ft.
31	8 " 8 "
27	9 " 13 "

We went to Adit 27, a short distance south of the incline-terminal. This level was 900 ft. long and is expected to tap ore at a distance of 10,000 ft., but it will get under the old Daisy workings at a distance of only 2000 ft. from daylight. The cost of the work is \$13 per foot, the contractor paying for supplies and laying a temporary track. The ground breaks well, but is hard enough to stand without timbering. Two Ingersoll-Rand

drills, 43 $\frac{1}{2}$ B. with 3 $\frac{1}{2}$ -in. cylinder, are used on a 12-ft. bar, which is steadied by a right-angle bar against the face.

The electric train took us up the mountain, along two sharp curves and one switch-back, past the powder-magazine, to the Tunnel Camp, as the upper settlement is called. Here is to be seen some of the wreckage left from the big snow-slide that killed 55 persons, including some women and children, in March 1915. On this gruesome subject I shall not linger, remarking only that it distressed Mr. Schley and the management exceedingly, and that everything was done generously that could be done for the victims and their dependents. The settlement stands in a clearing made in a dense forest of young pine, overlooked by high peaks. The Tunnel, or present haulage-adit, is 2100 ft. above sea-level, 9 by 13 ft. in cross-section, and 4336 ft. long. Eventually it will be extended through the mountain, right across the fairview ore-belt, and will then become truly a 'tunnel.' Alongside the track I noted the 12-in. air-pipe and the high-tension transmission line, carrying 6600 volts. At 4100 ft. this adit connects with the main ore-chute, 8 by 12 ft., extending for 1272 ft. between levels. We watched the loading of four cars, of 20 tons each, in four minutes. Ordinary are-gates, 39 in. wide, are used. There are two gates, so that one can be in service when the other happens to be blocked. A vertical board levels the load in the car and prevents contact with the trolley-wire. The ore is broken by a gyratory crusher in a chamber 400 ft. above the adit and the chute is fed 800 ft. higher above the crusher, so that a storage capacity of 2000 tons of crushed ore is obtained, besides 4000 tons uncrushed ore between the 1800 and 1000-ft. levels. Above the top of this chute, on the 1000-ft. level, there is 4000 tons more ore stored in similar raises.

On the 1800-ft. level, 400 ft. above the haulage-adit, is the gyratory crusher, where the ore is by-passed from the main chute over a grizzly made of wedge-shaped manganese-steel bars $3\frac{1}{2}$ in. apart. The ore passing through the grizzly joins the crushed product and falls back into the chute.

Ascending on the cage of the interior shaft, 10 by 20 ft., we reached the 1600-ft. level, which is 600 ft. above the haulage-adit. This shaft was made by raising 1275 ft. from top to bottom, 75 ft. being required for head-room above the hoist. There I saw the ore being dumped into the chute and also had my first look at ore in place. This level will be connected with an adit advancing from Furry creek, which parallels Britannia creek in the next valley southward. On the 1200-ft. level I saw a cross-cut that was intersecting the Third vein, and then rising to the 1000-ft. level I saw the hoisting-engine and the top of the big chute. The seven side-dumping cars emptied themselves automatically as they passed the opening, the wheels on one side running over a dumping bar so as to tilt the car. These cars are modeled on the design originated at the Phoenix mines of the Granby Consolidated. Listening to the ore as it

THE BRITANNIA MILLS. THE NEW ONE, ON THE LEFT, IS SHOWN IN COURSE OF CONSTRUCTION.

fell down the chute there came the suggestion that the drop must shatter the ore to pieces so that half of it passes through the grizzly above the crusher.

From the top of the chute it is only 1300 ft. to daylight, so we made our exit and saw the old camp and more traces of the big snow-slide. At the portal is the outcrop called the Bluff, which has been photographed often to suggest the bigness of the lode-channel, here fully 300 ft. wide of 1.8% copper. On the west side of the ravine is a glory hole on the Jane claim and the entrance of an adit 1000 ft. long, all part of the work done originally under Robinson's direction. But none of this early development sufficed to expose the real dimensions of the ore-belt. It is not a single vein nor even a series of them but a big width of schist enriched by seams of chalcopryrite. As yet 11 veins have been labeled in a belt 800 ft. wide; the average stopping-width of each vein is put at 30 ft. and the maximum at 80 ft.; but such measurements are only suggestive, the actual width of ground to be stoped is yet to be determined by further operations. In length the separate orebodies have been proved for 1000 ft., and in depth for 1600 feet.

The chalcopryrite is confined mainly to fissured channels in a silicified sericitic schist, adjacent to a diorite-porphry. Near the ore the schist is spotted with chlorite. Any rock broken in the course of exploratory work is sent to the mill if it contains 1% copper. At the existing price (28c. of copper such material can be treated as 'ore.' The run-of-mine contains about 2½% copper. These facts I drew out of Mr. Browning as he and I, in the congenial company of W. A. Wylie, the mine superintendent, sat on some timbers and munched our sandwiches.

Questioning them regarding drills, I ascertained that the Waugh 11A is used for stoping; for driving and cross-cutting, the Dreadnaught, a valveless hammer-machine of the water-Leyner type; for block-holing and light sinking, the Rand jack hammer and the Denver clipper; for glory-holing, the Rand 43½ and Dreadnaughts equipped with handles. By discarding the shell the weight of the last is reduced from 115 to 90 lb. Four Leyner No. 5 drill-sharpeners are in use and three Sullivan sharpeners. The mine will be worked by shrinkage stoping and 'glory-holing,' or big open-cuts.

While smoking the pipe of peace I enjoyed an occasional glance at the steep sides of Britannia mountain, heavily timbered fortunately, otherwise snow-slides would be frequent, and across the ravine the fir forest at the foot of the red rampart of Goat Mtn., on which the Rocky Mountain goat, or *mauiama montana*, disports himself freely.

Re-entering the mine at the 1000 ft. level, we ascended in the skip to the 500 ft. level, where I saw the Denver Engineering 75 hp. electrically driven hoist. Mr. Wylie said that it had been in use four years and had never given any trouble. In a chamber, 18 by 36 ft., near by, I found a No. 5 Leyner drill sharpener and a Sullivan sharpener, with a repair equipment, including a 10 hp. motor, drill press, grinder, and pipe threading machine.

Thence we walked to the other portal of the level, truly a 'tunnel,' which is 1500 ft. long, to the Furry Creek side of the mountain. The southern portal, called the Barbara, gave us a new outlook. A thick forest of hemlock, yellow cedar, and larch veiled the view, but between the tall stems I caught glimpses of snowy peaks, dark mountains, and the misty abyss of a deep canyon from the bottom of which came the roar of a torrent, like a stamp mill. Eastward the sky-line showed a gap in the Seymour divide, on the far side of which is the watershed of Seymour creek, flowing to North Vancouver. To that sky-line, fully five miles distant, the copper-bearing territory is said to extend. Turning round and examining the rock of the portal I could see the fresh face of Fairview schist, streaked with pyrite and chalcopryrite, but not rich enough to be 'ore.' The 500-ft. tunnel is in ore for 1000 out of its 1500 ft.; it intersects all the 'veins' from the Second to the Tenth, but it is not at right-angles to the ore-belt, so that the real width of ore traversed is 800 ft. The cross-cuts run due magnetic north and south; the 'veins' run S 80° E and dip 70° south with general uniformity.

On the 500-ft. tunnel horse-traction is employed. It is planned to replace this method with a storage-battery locomotive, also on the 600, 850, 1000, 1200, and 1600-ft. levels; in fact, wherever the present electric railway does not serve as a means of transport. A 3-ton Westinghouse locomotive with 'exide' (litharge) cells will pull 6 cars of 2 tons each. In breaking 2000 tons of ore daily, 2000 bits are blunted and 1½ tons of powder is consumed.

In the mine a reserve of 700,000 tons of ore broken by shrinkage is maintained. As for the total reserves, the mine is too young and undeveloped for a precise estimate, but 17,000,000 tons is said to be reasonably assured already. The total cost of producing copper is 7.3 cents per pound.

Metals Through the Sault St. Marie Canals

During the six months ending with September the American and Canadian canals, between lakes Superior and Huron and Michigan, reported as follows:

	1916	1915
Vessels	18,845	14,907
Registered net tonnage	51,701,240	38,578,998
East-bound:		
Copper, tons	83,669	95,373
Iron ore, tons	47,370,350	33,761,752
Pig iron, tons	29,896	6,914
West-bound:		
Coal: Hard, tons	1,609,481	1,448,734
Soft, tons	11,039,178	8,106,063
Manufactured iron, tons	116,411	134,137
Iron ore, tons	28,927
Salt, barrels	572,489	481,170
Total freight, including other materials	68,455,497	48,383,603

Of the totals, the American canal handled 55,229,198 tons in 1916 and 41,888,436 tons in 1915.

The Extra-Lateral Right—Shall it be Abolished?

By William E. Colby

There is no feature of the American mining law that has provoked more spirited discussion and against which a greater amount of criticism has been aimed than the extra-lateral right, or 'law of apex,' or dip right, as it is variously termed. It has become quite popular to present the arraignment of charges that can legitimately be made against the practical operation of this right and there is scarcely a meeting of importance connected with the mining industry where some one does not add to this volume of condemnation. In all this discussion, it is rare to find a word of commendation; not only are the advantages which flow from the exercise of this right ignored, but in the general demand for its abolition we find very little well considered thought given to the serious results of such action and few suggestions as to what steps should be taken to minimize the grave consequences that are bound to follow such a radical and far-reaching change in our mining law. We are too prone to assume that legislation is a panacea for all defects in existing laws and not enough attention is paid to the evils which inevitably flow from 'half-baked' remedial statutes. Judging from the published remarks of many who have criticized the extra-lateral right, the opinion seems to be quite prevalent that all that is necessary to be done to cure the ills that are inherent in the 'law of apex' is for Congress to pass a statute abolishing it.¹

COMPARATIVE TREATMENT. In a discussion of this character it is interesting to know whether other systems of mining law have similar features and what has been the result of their operation. It has been erroneously assumed by many that the extra-lateral right is a unique burden suffered by the United States alone. An examination of the laws of other countries shows that this is not a fact. Naturally we cannot expect to find in other countries an extra-lateral law identical in all respects with our own. It is the fundamental principle underlying this law that is vital,² namely, the right to mine on and pursue a vein in depth beneath surface ground that is not owned or controlled by the mine operator. In other words, the right to follow the vein in depth is independent of and is not measured by surface ownership, hence it is termed the right of extra-lateral pursuit. It is usually described as being opposed in principle to the common-law idea of ownership of land, where the owner of the surface is entitled to everything situated

vertically beneath. As Judge Lindley has pointed out in his treatise on the law of mines,³ the common law recognized the right of severance and frequently the surface-owner conveyed to another the right to mine a vein or mineral-bearing strata that penetrated or lay beneath his surface. However, the extra-lateral right as we ordinarily conceive of it has an element that did not exist in the common law. In the exercise of the extra-lateral right the vein may be pursued *indefinitely* in depth beneath the surface of adjoining owners who have nothing to say about the exercise of this right underneath their ground and are powerless to prevent it. The right has been created by statute or custom before their surface-ownership attached and the vein has been reserved and carved out of their estate. It is the statutory or customary origin of the right, giving it an indefinite sweep in depth and the fact that it is not at all dependent upon conveyance from private owners of overlying surface nor for its measurement upon the vertical boundaries of such surface-ownership that distinguishes the extra-lateral right from the common-law severance of minerals from the surface.

We have no definite information as to whether an extra-lateral right was exercised in ancient times. The existing record of these ancient mining laws is meagre and a great part of the mining was carried on as a sovereign venture so that the question of extra-lateral pursuit would seldom arise.⁴ It is only when there are adjoining private ownerships that a situation is created where the question becomes important.

Under the democratic control of Athens the silver-lead mines of Mt. Laurion were leased in small adjoining areas to individuals. One might expect to find the extra-lateral right a feature of the ancient Greek mining law were it not for the fact that these were flat-lying contact deposits occupying horizontal beds and hence unsuited to the exercise of any dip-right.⁵

SPAIN AND SPANISH AMERICA (PERU AND MEXICO). The fabulous wealth of the mines worked under Spanish rule, particularly in her possessions in the New World, stimulates our interest in her mining laws.

While we would naturally expect Spanish laws to reflect the influence of the civil law, we find little impress on her mining code from this source. In making an analytical study of the Spanish mining laws one is struck by the similarity of many of the provisions to those of the early Germanic mining codes, especially the right of

¹There are several bills to amend our mining laws pending before the present Congress. One of these would abolish the extra-lateral right without any provisions to relieve the serious consequences of such action. This discussion is prompted by this proposed revision.

²"The application of the term 'extra-lateral' to this right is of comparatively recent origin and the right existed long prior to this designation." 'Lindley on Mines,' 3d Ed. p. 568.

³'Lindley on Mines,' 2d Ed. p. 568.

⁴Those interested in the subject of ancient mining laws will find an excellent note at pp. 82-86 of Hoover's translation of Agricola, 'De Re Metallica.'

⁵See 'Hoover's Agricola,' p. 83, foot-note.

free mining, that is, the right of the individual to go upon crown lands or even lands belonging to others and upon making a discovery of mineral becoming entitled as a matter of right to the possession of a mining claim including the discovery. But the similarity is accounted for when we learn that in framing the mining ordinances of Spain "recourse was had to the laws of Germany."⁶

Article 5 of the Spanish mining ordinances of 1559, mentioned by Gamboa, as the "old ordinances," provides that,

"Whereas, by not designating the limit and space which the mines that shall thus be discovered are to have, there may result great confusion, differences and lawsuits; and the first discoverer may pretend that his mine and the right which by discovery may belong to him, cover and include the whole extent and continuation of the metallic vein, and that in the whole of such extent and continuation no person can interfere to prospect, search or work, from which may result great embarrassment and impediment to the discovery, and working and development of said mines,"

therefore, the article provides, the mine or *pertenencia* to which a discoverer is entitled shall have definite surface boundaries, namely, 100 *varas* long and 50 *varas* wide.⁷

This provision would seem to have eliminated the exercise of any extra-lateral right and this is further borne out by Article 29, which provided that if mines are staked out on the sides of another mine whose boundaries are already defined, because it appears that the vein inclines from the latter and may enter these side-claims, the Court shall protect these side-claimants and shall not permit the person who owns the mine from which the ore inclines, to follow the vein into these adjoining claims.

However, Article 30 also provided that if the boundaries of the mine from which the ore inclines are not already defined by the official survey and staking or if the ground into which the ore dips is not already claimed, then in either case the owner of the mine "shall be at liberty to continue to follow the said ore although he may go outside of his *pertenencia*." This latter provision clearly recognizes a limited exercise of the extra-lateral pursuit.

Ordinance XXX of the Spanish Mining Code of 1584, referred to by Gamboa as the "new ordinances," provided that if the ore in any mine shall be continuous with the ore of any other mine "and the two mines shall become one in the depth, the owner who shall have first sunk and made his way into the other mine, shall be entitled to the ore until the corner of the adjoining mine compels him to establish his boundaries. If it is found that he is outside of his true boundary he shall not draw, but he is still entitled to the ore he has mined

from the other's *pertenencia*, "inasmuch as he has acquired a right to it by the care and diligence used in working with more activity than his neighbor." The ordinance also provided that if a person took a *pertenencia* contiguous to the mine of another and there is no vein disclosed therein or if there is one and it contains no ore, but the claimant works "merely with the intention of profiting by the ore of his neighbor when he shall get within his boundaries" he acquires no rights "even though his neighbor's ore should take its course within his *pertenencia*; and our mining judges and justices shall determine it so, and shall not allow or permit such mines, not being upon a vein or ore, to be worked."⁸ It is quite evident that the foregoing provisions create and protect a modified form of extra-lateral pursuit.

Gamboa comments that "Of all the ordinances contained in the new code, or the old law, there are none more difficult, or which have been more frequently the subject of litigation in the courts than this." He states that when the vein extends outside the *pertenencias* of adjoining owners into unclaimed ground, each owner is entitled to work freely through the virgin ground upon the dip of the vein beyond his own limits and whenever the workings of rival claimants in this common ground meet a *guarda-raya* or boundary monument should be established beyond which neither could pass. Cases of this character gave rise to extensive litigation and a famous contest arose in the mining district of Guanajuato where Count de San Pedro del Alamo insisted that the dip of the vein that apexed in his Santa Anita mine

"was infinite in extent," that "the vein was his property, as far as it extended upon the underlay as being one and the same vein; and that as, when the vein, being what is called a deep vein, proceeds perpendicularly downward, the miner may work on to the antipodes, or to the infernal regions, as Amaya says; so, if the vein be inclined, its whole extent upon the underlay is granted to the miner."

The miners of this district had previously contended that the surface limits alone were to be within prescribed boundaries but insisted that the miner might work to an unlimited extent underground, whereupon in 1739 an order was issued that the property of the vein is not granted to an indefinite extent on the dip and that the underground limits of the mine must correspond vertically with the surface boundaries. The only exception is that already noted which permits a miner to follow a vein into unclaimed ground.

The early Spanish mining laws applicable to Peru provided that "if the principal vein of a mine should take its course without another's limits, it may be followed up without any impediment." If a vein divided before taking its course within the boundaries of a neighborhood mine, the owner was required to select one of the branches as his principal vein which he could fol-

⁶ Gamboa, op. cit. *Ord. and Code Mining*, *Golden Age*, 17, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

⁷ Mining Law of Spain & Mexico, Hallett, 1870, p. 12.

⁸ Hallett, op. cit. Gamboa, pp. 14-15.

low into his neighbor's ground. Gamboa notes that these regulations conform to the practice in the mines of Germany.

The ordinance of 1783 materially changed the Spanish mining law.⁹ Article I of Title VIII states that uniformity of size of surface claims cannot be observed underground and at the same time equality between claimants preserved, for the inclination of the vein with the plane of the horizon makes the amount of vein-material included within the *pertenencia* greater or smaller and it may well happen that when a miner after great expense and labor reaches the boundaries of his claim where the vein begins to be rich, an adjoining owner, who has placed himself at that point with more cunning than labor, may compel him to stop working further "so that from this arises one of the greatest and most frequent causes of litigation and dissension among miners."¹⁰ As a result, the new code provided that each miner is entitled to 200 Castillean *varas*, which are called *de medir* (long or running measure) along the thread, direction, or course of the vein taken on a level. To square the claim a rectangle was formed by taking 100 *varas* on each or either side of the vein, if the vein were vertical, and this width increased as the dip of the vein might flatten till the claim attained a maximum width of 200 *varas* for veins dipping at an angle of 45° or less. The ordinances voiced the opinion that by the time the vertical boundaries of the claim were reached the vein will have been considerably exhausted.

Article 14 referring to the permission granted under the former law of 1584 to enter another mine and continue following the vein until the owner of the other mine can extend his workings so as to stop the adverse entry, states that it is "the most fruitful cause of the bitterest law-suits, dissensions, and disturbances among miners" and the adverse entry occurs more often through fraud or accident rather than as the result of merit or industry. Therefore, entering the *pertenencia* of another is prohibited.

Article 15 provides for an exception, however, and if a miner pursuing his working fairly and following his vein reaches the *pertenencia* of another or discovers there a vein undiscovered by the adjoining owner, he shall be obliged to give such adjoining owner immediate notice and thereafter share equally with him all that he may extract from the adjoining *pertenencia* and for failure to give such notice of invasion of the other's territory he lost all right to the ore taken out and also paid double its value as a penalty. The other owner could stop this invasion at any point that his own workings encountered the invader's.

Article 16 continued the right to follow the vein into

unclaimed adjoining territory but compelled the denouncing of a new adjoining *pertenencia* covering the vein.

Article 17 confirmed each owner to that portion of the vein included within his boundaries and specifically denied the right either to the discoverer of the vein or to the owner of the apex to "claim it in its whole extent, or wherever it may happen to be."

This was the mining law in force in Mexico from 1783 up to the time of discovery of gold in California. Raymond¹¹ makes the comment that

"this law is remarkable for an attempt to reconcile the two systems of square and inclined locations by an elaborate graduation of the size and shape of the surface claim according to the dip of the vein."

He points out the impossibility of administering such a law in accordance with the facts, for an opening 10 yards deep was required to determine the dip of the vein, which was then erroneously assumed to follow a uniform course and dip.¹²

The ordinances of 1783 have long since been superseded by mining codes which have abolished the graduated forms of claims.

AUSTRALIA. The local court regulations of Maldon of March 6, 1857, provided that the width of a claim should be 100 feet on each side of the line of the 'reef' with the dips and angles of all 'reefs' within the boundary and the right to follow them to whatever distance they might dip.¹³

In New South Wales the mining regulations of August 5, 1858, provided that:

"Miners occupying any portion of a quartz reef or vein shall be entitled to follow and work it in any direction that such reef or vein may take. . . . Provided, . . . that when any reef, vein, or bed of quartz shall lie nearly horizontal, or at a less angle with the horizon than 20°, the holder of any claim shall be only entitled to follow such reef, vein, or bed of quartz in the direction of the dip, for a distance not exceeding 50 yards from the point where they commence to sink in search of any such reef, vein, or bed of quartz."¹⁴

These extra-lateral provisions were probably patterned after the miners' customs of California, since Californian miners are known to have taken a leading part in this early mining in Australia. The use of the terms 'dips and angles' is similar to language employed here by the early miners. Where the vein was inclined, the limits of

⁹Mineral Resources (1869), p. 196.

¹⁰*Ibid.*, p. 198.

¹¹Law of Gold Mining in Australia and New Zealand, Armstrong (1901).

¹²If this provision was not suggested by the Germanic extra-lateral law, it is at least the strongest kind of circumstantial evidence, for in most of the mining districts of Germany veins that dipped at an angle of less than 20° were termed *flütze* and no extra-lateral right could be acquired to such deposits.

¹³See, 'Mining Laws of Australia and New Zealand,' Veatch (1910).

⁹These ordinances are set forth in full in Halleck's 'Mining Laws of Spain and Mexico,' pp. 189-315.

¹⁰In the light of recent criticism of the extra-lateral right, it is amusing to note that this ordinance attributes excessive litigation to the inflexible vertical boundary system. Dissatisfaction with existing conditions and enthusiastic conviction that a change will result in complete relief, is a common characteristic which is not confined to the present day.

a claim were determined by establishing a base-line passed through the 'peg' or discovery-point on the apex of the vein and "another point visible and as distant as possible on the known line of the reef" or in case the position of the reef (vein) was not sufficiently known, an arbitrary point was selected and from this base-line right-angled lines were extended out in the direction of the dip of the vein. This method of defining boundaries within which the miner could work is almost identical with the plan that was later adopted on the Comstock lode for the settlement of disputes over boundaries.

In 1862 the regulations were altered so that a claim had a width of 100 yards and the owner was entitled to all veins found therein, instead of one vein only as under the former act, and could follow any vein into unoccupied ground.¹⁶ In 1866 the system of vertical boundaries was adopted because the extra-lateral system was "found to lead to disputes."

In Western Australia under existing law, individual leases are granted of areas necessary to work the vein to a depth of 3000 ft. and if the mineral is gold the length along the outcrop of the vein shall not exceed 66 chains, and if mineral other than gold the distance along the outcrop shall not exceed 90 chains. This right to mine in depth is virtually equivalent to the exercise of an extra-lateral privilege.

RHODESIA. All property in minerals and mining rights in Rhodesia has been granted by the Crown to the British South Africa Company. The system of mining law in force there was adopted in 1903 and is largely copied from the American law.¹⁷ A 'reef claim' is a parallelogram 150 ft. long on the course of the vein with a width of 600 ft. at right angles to the length. A 'block' is a group of not to exceed 10 contiguous claims, thus forming a parallelogram 1500 by 600 ft., the exact size of a lode-claim under American law. The 'extra-lateral right' is defined in the ordinance to be "the right of following a reef on its dip in any block beyond the limits of the vertical block." The "course of a reef" is defined to be a line on the surface marking the intersection of the centre of the reef with such surface. If the reef were 'blind,' that is, situated below the surface, the points where it approached closest to the surface were projected vertically upward. This is the 'course of the apex' or 'lode line' of the American law.

The miner had the "extra lateral right of pursuit of such portions of his discovery reef on its dip outside the limits of his vertical block as are comprised between vertical planes indefinitely extended and passing through the end lines of his block."¹⁸

BRITISH COLUMBIA. The various provinces of Canada have adopted the vertical boundary system of mining law but British Columbia in 1891 passed a Mineral Act, Section 31 of which provided that:

¹⁶Here we have a provision similar to those contained in the Spanish mining codes already noted.

¹⁷"Mining Law of the British Empire," Alford (1906), p. 197.

¹⁸The striking similarity of this law to the American mining law is evident.

"The lawful holders of mineral claims shall have the exclusive right of possession of all the surface included within the lines of their locations, and of all veins, lodes and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side lines of such surface locations," etc.¹⁹

The section also provided that if a location were laid crosswise of a vein instead of along its course the locator secured only so much of the vein or lode as it crossed and the side lines became the end lines for the purpose of defining extra-lateral rights. A location was deemed to be laid crosswise when the angle made by the centre line of the location and the general course of the vein was greater than 45 degrees.

This section of the Act was repealed by Section 2 of the Amendment Act of 1892 which provided that "The owner of a mineral claim shall be entitled to all minerals which may lie within his claim, but he shall not be entitled to mine outside the boundary lines of his claim continued vertically downward." Sub-section B preserves rights of locations under the former acts.

As a result of this brief period during which the extra-lateral right was sanctioned, rights to a number of such mining claims became vested. The British Columbia reports indicate that several cases have arisen where these rights are involved.

Sufficient examples have been presented to indicate that there has been a powerful tendency at work based on fundamental reason and natural law to segregate the mineral-bearing vein from the surface, and to grant the vein to the miner. Instead of confining him to inflexible surface boundaries extended downward vertically, the tendency has been to make these boundaries more elastic so that he could, in the interest of economy and justice, follow down on his vein, which is the principal thing sought, and which has no logical relation to the overlying surface. The surface ownership was usually segregated from the underlying mineral and vested in another who might be devoting it to agricultural or other pursuits. This severance is in line with the highest economic use of natural resources and embodies the modern conception of conservation. The surface was frequently used for convenience in marking out a perimeter merely to place a limit on underground workings, but the perimeter could be varied or extended according to the nature of the deposit, and as underground development might indicate was most equitable and economic. Frontage claims also accomplished the same object.

The pure type of extra-lateral right has unquestionably given rise to a vast amount of litigation, and this fact has resulted in its abolition in most countries where it formerly existed.

¹⁹This is identical in language with the Act of 1872, p. 2322, U. S. Rev. Stat. from which it was unquestionably taken.

The Prospector's Field-Work

By Herbert Lang

It appears likely that the question of what shall be done for or to our mining prospectors will have to be settled by the prospectors themselves. It is generally conceded that the day of discovery is past, the prospector must settle down to the more prosaic life of grubbing within restricted areas. Life generally is getting prosaic, so he need not complain. The feverish charging about from one country to another, from Cape Nome to Cape Horn, and making startling discoveries on a diet of 'sow-belly' and 'self-rising' is out of date. Probably the prospector himself will realize that he must harmonize himself with the sobered spirit of the age and bring his exertions into conformity with it. One of the principal demands today is for thoroughness and accuracy, in which respects the average prospector has much to learn. Necessity will compel him to do his work more thoroughly, covering with more pains a much more restricted area, and recording with more care what he may see. While his chances of making sometime a great discovery are, as generally conceded, becoming more slim each year, there is compensation in the largely increased opportunities of making small finds, in consequence of so many of the minor minerals coming into use.

What is required now is the careful investigation of comparatively small areas, and the recognition of all mineral occurrences of probable value. This must ultimately be done either by the Government geologist, the professional engineer, or by the volunteer prospector—or more likely, by the combined energies of all of them. Think of the sad waste of energy involved in desultory traveling over vast areas, travels that are repeated time and again by other prospectors, and engineers also, in misdirected attempts to find a mine. Hundreds of men follow in each others' footsteps without having received a single idea from their predecessors, and without leaving a shred of information to their successors. Nor is this waste of effort confined to prospectors: engineer after engineer, 'expert' after 'expert', follows in the never-ending quest, without any useful result to the public and with little gain to themselves. In this connection the important question is how to make the observations and findings of the more intelligent of the travelers of avail to the general public interested in these matters.

It seems to me that proper prospecting should be looked upon as a matter of public concern, to be fostered by the counties, States, and the Government. Your correspondents have made various suggestions, looking mainly to the private employment of this class of men, regardless of the patent fact that the revelation of mineral deposits is really a matter of public concern. The

Government is beginning to realize this fact, and the various States do something in this direction; but the State and National authorities thus far have merely laid the foundation for a thorough study of mineral deposits. Now, there is a vast mass of unpublished knowledge about particular areas and particular deposits that ought to be made accessible, to the end that the willing investor may know where to go without the wasteful and generally ineffectual process of sending a special representative here and there, to run down vague rumors and sift the reports of interested and too often unreliable parties. I can think of no better way than for communities to club together and hire qualified men to critically examine the lands about them and record carefully their findings, which, if the work is well done, will become a part of the stock of scientific and practical information upon which the mining industry will thrive. The geology of the country has been fairly well sketched, and a mass of miscellaneous facts collected in various ways by professional and other persons, and now if to this groundwork can be added in elaborate detail the descriptions of individual deposits the work will be in a measure finished.

The prospector may find his billet in this, but in order to perform such work properly he will have to fit himself in a different manner. He will need instruction. He will have to make himself conversant with mineral appearances. He should know somewhat of mineralogy, almost a sealed book to the wanderers of the past. The ability to test and determine minerals should be a part of his education, and involve some knowledge of chemistry. Without necessarily being a professional chemist, he should at least have some knowledge of assaying also. These things are not difficult to learn, and it has always been a matter of surprise that prospectors heretofore have been so regardless of the advantages of knowing how to make the simple tests indispensable to the proper performance of their tasks. A blow-pipe outfit, sufficient for such needs, may be carried in a suitcase, and if in addition to this more apparatus is thought to be essential, the whole weight and cost of materials would be no great matter. I would not minimize the trouble of learning the proper use of analytical or other scientific appliances, but I have never thought of assaying or blow-pipe work as anything but simple. People who, like miners and prospectors, constantly work in or upon minerals, surely ought to be able to tell them apart; but how often do you meet one competent to employ the commonest test to indicate the composition of a mineral? With every opportunity and inducement to become skilled in geology and mineralogy they continue in a state of comparative ignorance that would discredit a

schoolboy. Some men will work ten years in the mines and still be unable to tell you the difference between quartz and calcite, they will still divide all rocks into granite, lime, and porphyry, call all blue minerals 'bromides,' and prate about 'true fissures' as long as anyone will listen to them. I do not, however, hope to improve this state of affairs radically, for it would be as hard to get an old-time prospector or miner to learn anything out of books as it would be to get a young mining graduate to cease calling himself an engineer. I have often, but with what result I know not, advised young graduates to set up in some recognized mineral locality, and while working as the local assayer and surveyor make a close examination of all the mineral resources in the neighborhood—an examination that in the nature of things might take several years; but the time would not be lost even if no profitable discoveries rewarded the seeker.

My solution, then, of the question of what to do with the prospector would be to convert him into an examiner of mines, or, more strictly speaking, into an investigator of mineral deposits, and keep him at work in one spot. I would make his work available to the multitude by compelling him to keep accurate notes on what he did, and

I would have these notes published at the public expense and kept for the use of the mining industry. I would have the data regarding every mineral deposit in this State put into proper form for reference. It should be the habit of every qualified person, when he visits a mine or a prospect, to fill out a blank with the bottom facts concerning that mine, and to file the notes with a public official. Furthermore, I would see to it that every visitor to a mine, such for example, as our peripatetic experts, contribute his share to the sum of information. Taken as a whole, I do not regard the ordinary mining report as of much value, but he would be but a poor observer who did not find out at least a few useful facts in his peregrinations. By such means I should hope that in time the presumed necessity for both prospector and expert would have largely disappeared, and the mining industry have been placed upon a more secure foundation.

NITRATE PRODUCTION of Chile during August was 5,396,981 quintals of 101.4 lb. each, of which 4,338,013 was exported. In this month of 1915 the total output was 3,443,409 quintals. The present rate is equal to the normal quantity as in 1913.

Milling and Cyaniding Costs at Grass Valley and Nevada City, California, in 1915

By R. E. Tremoureaux and F. A. Vestal

A comparative cost sheet has been worked out by us on the following mills and cyanide plants:

Mill	Ore Stamp-		Stamps		Company
	crushed, duty,	tons	No.	Lb.	
North Star	51,830	3.8	40	1950	North Star Mines
Central	58,030	3.9	40	1950	" "
Champion	38,850	1.97	20	1950	" "
Empire	81,850	4.8	40	1950	Empire Mines
Pennsylvania	29,500	1.9	20	1950	" "

*Changed during the year

	MILLS				
	Empire	North Star	Central	Champion	Average

Ore-Sampling Conditions in the West

By T. R. Woodbridge

*An accurate knowledge of the constituents of an ore is indispensable to the success of all mining enterprises, especially when the ore is sold to a custom plant of any kind. A large part of ore sampling is not done on a scientific basis. In most sampling-plants there is a lack of uniformity of methods. The Bureau of Mines has investigated the subject with a view to increasing efficiency in the operations. In California, Colorado, Montana, Nevada, Utah, and Washington, 48 plants were visited, sampling ores of gold, silver, lead, copper, and zinc.

Ore in place in a mine is rarely of uniform metal-content, and the process of extraction generally aggravates this condition, as the more heavily mineralized parts usually break-up more readily, so that the finer particles contain more of the valuable constituents than the coarser ones. With every crushing during sampling this difference persists to a varying degree, even after the final lot has passed 120-mesh. In considering the reliability of any sampling method the tendency of the ore to segregate should not be forgotten. In a large proportion of systems used in the Western States the theory of sampling has been given proper consideration, and many plants are operating on correct principles.

Where the more valuable ores are sampled it is often customary to divide the sample at certain points in the process, and make duplicate, triplicate, and even quadruplicate samples, each of which receives an entirely independent but similar treatment during the later process, and is assayed separately. This checks errors and gives an average for settlement with sellers of ore.

Ore is generally weighed on platform-scales, varying in capacity from 60 to 100 tons. Weighing has improved considerably during the past 10 years. Scales are frequently tested by the Western Weighing Association. Weighing is generally carefully done, but undue haste was noticed in some instances. The weighing of a slowly-moving train of cars coupled together is not now in vogue, the Association stopping the practice. If horses are straining at a loaded wagon being weighed, several hundred pounds may be added to the net weight.

Low-grade and uniform ores that will not stand the cost of a more exact method may be sampled by the 'grab' system, whereby small quantities of ore are taken at random by hand or a shovel from the pile or car. Careful men obtain fairly accurate results in this manner. Pipe sampling can be used for fine material only. Neither of these methods were found to be in general use, and are rarely suitable for ores.

Coning and quartering is practised exclusively in two of the plants, and in combination with other sampling

methods in twenty-six others. Advantages claimed are that an expensive equipment is not required, the method can be used where mechanical apparatus is not procurable, it is applicable to all kinds and conditions of ore, it may be used for high-grade lots without loss, and as the ore is in sight of the seller all the time the system often pleases him. Fig. 1 shows a plant that includes

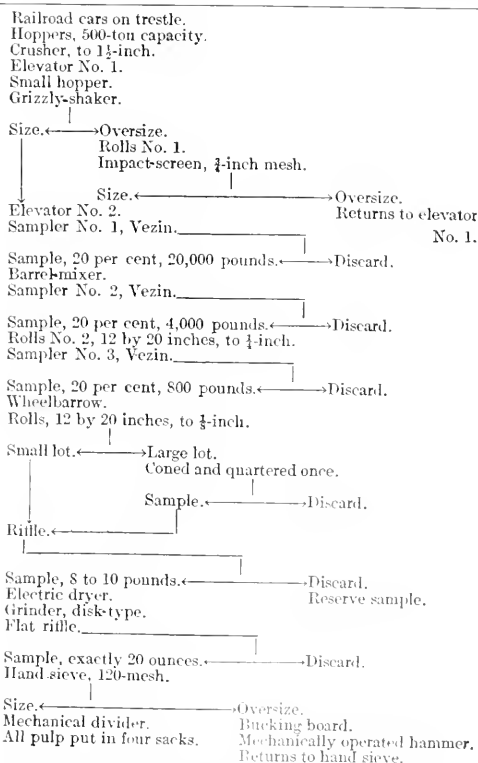

FIG. 1. SAMPLING-PLANT THAT INCLUDES CONING AND QUARTERING.

coning and quartering. There are numerous disadvantages as it is expensive, time is lost, and salting is possible.

In coning operations, or forming a cone on a floor, a rough separation of fine and coarse particles takes place, even when the ore is finely crushed. Uniform mixing of various sizes is impossible. During flattening of the cone for subsequent quartering, care is necessary not to aggravate the segregation of particles. By the 'bench' system, in which a number of cones are spread out each

*Abstract from Technical Paper 86 of U. S. Bureau of Mines.

time above one another, segregation is lessened, but the trouble is still evident.

None of the plants examined used the fractional shoveling method of sampling exclusively, but all of them using coning and quartering and six part-mechanical plants use shoveling at some point in their operations. By fractional shoveling is meant every second or tenth shovelful of a lot of ore is thrown into a special receptacle for sampling. It is a convenient method, but is no more reliable than coning, and also men shoveling at high speed are not likely to be accurate in counting.

Many advantages are claimed for mechanical sampling systems. Save for cleaning the machines and unloading ore, no hand labor is necessary. The operation is continuous and fast. With proper precautions the susceptibility to error and manipulation in hand methods is eliminated. All custom sampling-plants employ the mechanical system. One plant can compare its system with others to which ore is forwarded. A well-conducted custom plant studies comparative returns from different smelters and mills, and frequently makes shipment of 'split lots' of the same ore to two or more reduction works. Re-sampling of several consecutive portions of the same lot of ore is a practice, the lots being sent to as many different smelters for comparison of results. The custom plant does not buy all the ore it samples, but usually does a large proportion of its business in what is termed 'sampled-in-transit' ore, the sample obtained to act as a check on the assay given by the purchasing-plant. Many objections are made to mechanical sampling, as the initial cost and renewals are heavy, dust may salt samples, machines are difficult to clean thoroughly, and improperly constructed spouts or other apparatus might prevent good sampling.

Devices for mechanical sampling operate on either of two distinct principles that separate them naturally into two classes—stationary devices which continuously divert certain fixed sections of the stream of ore for the sample, and moving devices which are so operated that during several fixed periods per minute, they divert the whole of the moving stream of ore for the sample. These devices are commonly and more graphically described as those taking part of the stream all the time, and those taking all of the stream part of the time. The first class of the mechanical samplers now in use is represented by the whistle pipe and the bank or combination riffle. In the former the ore is fed into a vertical iron pipe with five notched openings cut half way through it, each at an angle of 90° from the one immediately above. Above each notch is a cast iron liner, which diverts half of the ore each time to a reject bin. The sample represents $\frac{1}{2}$ of the original feed. The device is a good one, but the ore cannot be re-crushed until it has passed through and is then $\frac{1}{32}$ of the original bulk. The bank or combination riffle consists of five riffles set in one frame, the top riffle being placed over two lower ones which are in turn followed by two more set below them. The ore is fed from a chute or hopper to the first riffle, where the stream is divided into a number of smaller streams, which are

other one falls on one side and the rest on the opposite side of the riffle. From the spouts on both sides of the first riffle the streams of ore impinge on inclined iron aprons, *k* and *k*, by which they are diverted to the two riffles *cd* and *ef*, smaller than *ab*, and so on, as shown in

FIG. 2. WHISTLEPIPE AND BANK OR COMBINATION TYPES OF SAMPLING-APPARATUS.

ore falls into the reject receptacle. This type has some special advantages in addition to those already ascribed to mechanical samplers. The more common examples in use at the plants visited are the Snyder, Vezin, Chas. Snyder, the Brunton vibrating, and the Brunton oscillating machines.

The Vezin is used at 25 of the plants, and is used in combination with almost every present method of sampling. Details of construction have been changed at many plants, but the principle remains the same, and in its simplest form is as in Fig. 3. The sides of the sample-spout should be vertical, the top edges should be inclined at an angle of approximately 58° to the horizontal, and should deliver the ore in a sheet parallel to the edges of the spout as they pass beneath it, and that the sampler should be so rotated that the speed of the sample-spout should approximately equal the horizontal speed of the ore when it reaches the spout.

In Fig. 4 are shown the Brunton vibrating and oscillating samplers. They are used at two and six plants, respectively. The illustrations are self-explanatory. In the oscillating machine as many as 72 samples per

minute may be taken. Care must be taken in the design of this apparatus.

Synchronism takes place in mechanical samplers, and when two or more machines are operated as a train or in series there is necessarily a constantly recurring cycle of their relative positions. For instance, if two hori-

FIG. 3. A VEZIN SAMPLING-MACHINE.

izontally rotating machines are so placed that one is directly beneath the other, and are given the same speed of rotation, the sample spouts will always keep the same angular distance apart. If the machines are given different speeds, the sample spout of one will catch up with

metallies, fineness, weighing, salting, and comparison of assays.

The paper concludes with flow-sheets of 55 sampling systems at the 48 plants investigated. The general form

of the flow-sheets is a modification of that used by D. W. Brinton in his 'Modern Practice in Ore Sampling.'*

FIG. 4. BRUNTON VIBRATING AND OSCILLATING SAMPLING-MACHINES.

and pass that of the other with a regularity like that with which the minute hand passes the hour hand of a watch. Mills have been entirely re-constructed to avoid this condition. An elevator or Chas. Snyder sampler lessens the trouble, but the better system is to interpose between the samplers a hopper, a revolving barrel, or a shaking tray. Eight plants use the barrel-mixer, 19 the tray, and 6 both systems.

The final work of sampling includes the drying, grinding, and sacking of the sample after it has reached the bucking-room. Fig. 5 shows a large sampling-plant, the latter part of which explains reduction of samples to the final lot for assay. Much care is needed in the various operations of drying, grinding, screening, treatment of

THE IDEA seems prevalent among men operating small properties in Arizona that the smelters and custom mills have, in many cases, given false returns on ores that are sent in for smelting and treatment. With a view to ascertain the facts of the case, the Arizona State Bureau of Mines has conducted an investigation and has found that it would be quite impracticable for any smelter or mill to so falsify its method of sampling as to give low returns and still give the shipper one-half of the sample to allow check-assays to be made. Bulletin No. 26 of the Bureau, entitled 'Mill and Smelter Sampling,' by H. J. Stander, was written with the idea of showing the small shipper how to sample, so that he may sample his ores before shipment to ascertain the correct value, thereby having a check on the smelters.

Concentrates

Answers of the MINING and Scientific PRESS to questions and give information dealing with the various phases pertaining to the practice of mining, smelting, and concentrating.

THE MELTING-POINT of copper is 1100° C. (2012 F.); that of aluminum, 655° C. (1211 F.).

BARYTES is used principally as a pigment in mixed paints and in the manufacture of lithopone, a white pigment.

BLACK DAMP is defined by the U. S. Bureau of Mines as an accumulation of carbon dioxide and nitrogen in excess of the percentage found in pure atmospheric air.

POTASH is being recovered as a by-product in cement manufacture. Waste dust, which contains considerable potash, is precipitated by the Cottrell electrical process.

THE LACE-HOLES in a belt reduce its strength by at least 25%. Care must be taken not to make a bulky splice which prevents the belt from passing smoothly over the pulleys.

BLACK HOLING in breaking boulders is more efficient than mud-capping which is so commonly used. The former requires less explosive than the latter but requires more time.

CEMENT GUNS have been used to close crevices on the surface where water enters mines during the rainy periods. Work must be done when crevices are dry as the gun will not operate against flowing water.

"SALE PRACTICE AT BLAST-FURNACES," a manual for foremen and men, by F. H. Wilcox, is the title of Technical Paper 136 issued by the U. S. Bureau of Mines. A valuable lot of practical suggestions and warnings are given.

THERE are numerous sections of land in the Western States, owned by the railroads, where these sections are sometimes many miles outside of the zone of 20 to 40 miles lying on either side of the railroads, and in which the railroad companies own all the odd-numbered sections by grant from the Government. These outside sections are lion lands selected by the railways in place of those sections within the zone of the grants, which, for one reason or another, were expected from the original grant and to which the railroads were unable to obtain title.

ZINC and production of the United States in 1913 was 516,000 lb. while imports were 1,321,750 lb. Since the War started, Europe supplies have been cut off and at Salt Lake City, the U. S. Bureau of Mines, which is experimenting on the treatment of bottegosh complex zinc lead ores, and prospect, have been determining

whether the zinc in such ores could be produced as dust from solutions of zinc. H. J. Morgan and O. C. Ralston, in a paper prepared for the American Electrochemical Society, concluded that by depositing a sponge metal from solutions by electrolysis it is possible to get a zinc product that on drying crumbles into zinc-dust. The sponge is obtained from zinc-sulphate solutions, also chloride solutions.

THE FIRST DREDGE-BOAT for gold built in the West was on the Feather river, near Oroville, in the summer of 1878. It was not a paying investment nor a mechanical success. The boat was 60 ft. long and about 30 ft. wide. The gravel was elevated by creating a vacuum in a stand-pipe connected with a tube the lower end of which was in contact with the bottom of the river. This was done by injecting a jet of steam into the stand-pipe and then a stream of cold water to condense the steam. The tube was raised by mechanical means and the gravel dropped into a sluice-box for washing. The bottom of the river was so uneven that the suction was not great enough to remove the gold from the crevices.

TESTS recently were made to determine the relative resistance of iron, steel, and a number of alloys, to atmospheric corrosion. Taken as a whole the results indicate that copper-bearing steels are superior to any of the other materials tested. It was found that pure iron, including charcoal iron, is more resistant than the ordinary steel but that the addition of 0.25% of copper to the steel causes a remarkable increase in its ability to resist atmospheric corrosion. The addition of copper to pure iron also results in an increased resistance but not to the same extent as the addition of a similar amount to steel. It is believed that the copper exerts a greater influence in the steel than in iron, due to the combined presence of copper and manganese since the chief difference in iron and steel is in the manganese content. The exact function of this combination in the alloy is as yet not clearly understood.

IN LOCATING mining claims the locator should endeavor to ascertain if possible the direction of strike of the vein or orebody and lay out the claim in the direction of this strike. Failure to give proper attention to this important matter may eventually prove to be expensive, for the exercise of the extra-lateral right is directly affected by the relation of the strike of the orebody to the side lines of the mining claim. In the case of a vein the direction of strike is generally apparent, but where the orebody is irregular in form it is often puzzling to determine the strike before considerable development work has been done. Often, where orebodies are large and irregular in form, giving little evidence of strike in any direction the formation in which the ore deposit occurs may be observed to have a strike, due to schistosity, or sheeting, or the strike may be determined by the dip of the strata. When this strike of the rocks can be ascertained it will usually be found that the orebody conforms approximately to it.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

DEADWOOD, SOUTH DAKOTA

TUNGSTEN DEPOSITS DESCRIBED.—GOLDEN WEST AND SLAVONIAN MINES.—HOMESTAKE'S NEW HOSPITAL.—THE BLACK HILLS SUMMER SEASON.

As has been pointed out in these letters, the principal tungsten ores of the Black Hills contain the mineral wolframite; some scheelite has been found. In the Bear Gulch district scheelite is almost invariably found, in small quantities, in the placers. It is hardly rich enough to save except as a by-product of gold mining. Wolframite, though, is found in three distinct geological formations. It occurs in quartz veins in the schists, notably in Pennington and Custer counties; in pegmatite dikes in those counties, and in and adjacent to the Cambrian quartzite in some portions of Lawrence county. In the past few months the available supply of wolframite ores has been materially increased by new discoveries. One of the most important of these finds is that of W. L. Faust and associates. Their property, in Harney canyon, south of Hill City, shows an immense pegmatite dike that gives promise of developing into a large supply of tungsten ore. Some rich specimens have been found, but the average grade of the ore, when mined in large quantities, would probably not be above 2%. In the neighborhood of Deadwood a number of tungsten discoveries have been made. This ore occurs in intimate association with the Cambrian quartzite. At times it is found in the quartzite, and at other times immediately above it. Both classes of deposits are undoubtedly replacements of some of the limy or dolomitic ingredients of the quartzite and adjoining beds, by the tungsten mineral. Two miles south of Deadwood, near the head of Two Bit gulch, some of the finest ore yet found in the Black Hills has been taken out. Here the crystals of wolframite are unusually well developed. They often attain a length of $\frac{1}{2}$ to 2 in., and their structure—radiating groups of prisms—add attractiveness and make them valuable as specimens for collectors. Almost within the city limits of Deadwood, north-west of the business section, quartzite ores have been found that with a fair price for tungsten would make profitable milling schemes. During the past summer systematic prospecting has revealed a far greater extent of wolframite ore than was, prior to that time, believed to exist. High-grade, which could be profitably shipped any great distance, is not plentiful, and additional custom mills seem to be needed. But before they can be built contracts must be arranged so that a market can be assured for their product. Black Hills' miners would welcome and support a mill, conveniently situated, which would buy ore on a basis of around \$20 per unit.

After cross-cutting 170 ft. of vein-matter and 20 ft. of a slate horse, the Golden West management has decided to drift south on the vein for 100 or 150 ft. and cross-cut again. The disclosure mentioned was made in the adit, work on which was started last spring. At a point nearly 400 ft. from the portal the foot-wall of the vein was encountered. Further work in a westerly direction revealed the ore-formation described, but as yet the hanging wall has not been found. The south work will be in the direction of, and eventually immediately beneath, the open-cut from which several thousand tons of ore has been milled.

L. P. Dove and others (the former last winter was instructor in chemistry and assaying at the Lead public school) have had

a successful summer's run on ore from the Slavonian ground, near Elk mountain. They have been operating the Deadwood Standard mill, which is conveniently situated within a few hundred feet of their workings; but will probably suspend milling during the winter, and devote their energies to mine development. The ores that have been treated occur in one of the upper members of the horizontally-bedded Carboniferous limestone. This stratum is about 50 ft. thick, and is rather irregularly mineralized. Where exposed by erosion on the sides of gulches it often shows faces of ore 20 ft. thick, but when followed into the hill it gradually pinches until it is no longer profitable. The present operators have been confining

THE BLACK HILLS REGION OF SOUTH DAKOTA.

their efforts largely to outcrop ore. It is more abundant, easier to secure, and gives a satisfactory extraction in the mill.

The Homestake company has outgrown its hospital, a building constructed years ago, and has decided to erect a new and thoroughly modern structure on the Jentees corner, at Lead. The new hospital, equipped, will cost \$100,000. Dr. F. E. Clough, assistant surgeon, and A. J. Blackstone, of the engineering department, are now in the East making notes on the arrangement and equipment of modern hospitals. The Homestake hospital and medical service is maintained by the company, and is free to all of its employees and their families. The new building will make this uniformly excellent service even better than it has been in the past. Work will begin this winter or early next spring, as the plans will be prepared as soon as the investigators return.

Taken as a whole the Black Hills has experienced a prosperous summer, insofar as the mining industry is concerned. There has been more than the usual amount of development.

TORONTO, ONTARIO

MUNITION BUSINESS AND STEEL—ZINC AND COPPER BRITONS—
FORTHPIKE, NICKEL AND POLYMER.

Recent statements to the effect that no more orders for War munitions were likely to be given to Canadian manufacturers by the British government have been shown to be entirely unfounded, as an official announcement by the Imperial Munitions Board at Ottawa states that it has received instructions to place additional contracts to the value of \$60,000,000. The total value of the munition orders secured in Canada since the beginning of the War is \$350,000,000, of which contracts amounting to \$185,000,000 were awarded during the present year. The Imperial Munitions Board states that during July and August operations were delayed owing to the difficulty of procuring steel and forgings, but that conditions have since improved and the output of shells is increasing in number each week. The quantity of shrapnel shells now produced complete has reached nearly 250,000 per week. The difficulty in securing deliveries of the new equipment necessary for the manufacture of the larger size shells caused slow deliveries, but most of the plants required these installations are now in operation. No further troubles as to raw material is anticipated as arrangements have been made to secure all the steel required. The policy of the Board will be to confine new business to the plants already equipped and in operation. The steel industry is very active. Thomas Cantley, president of the Nova Scotia Steel & Coal Co., states that the company is now turning out steel billets at the rate of 15,000 tons per month or more than double the output of a year ago. He estimates the total output for Canada for 1916 at 1,500,000 tons compared with 975,000 tons in 1915, and 1,350,000 tons in 1914, which was the record year.

An extensive and rich zinc-copper deposit at Cape Breton, 30 miles north-west of North Sydney, Nova Scotia, is being opened up to the great demand for metals for the War. It has recently been secured by Toronto capitalists, whose representative, H. H. Sutter and Co., now in Nova Scotia making arrangements for development on an extensive scale. The surface indications are stated to be splendid. The main vein 10 ft. wide, has two branches, the first 10 ft. wide, and a second vein 10 ft. wide has also been traced for some distance. Assays of ore from the main vein are estimated to contain 34% zinc, 21% copper, 10% lead, and small quantities of silver contents. The owners have been offered contracts for large quantities of zinc, lead, and copper, and are anxious to secure permission to make shipments as soon as possible.

The recent four-weekly statement of the Dominion Consolidated for the period ending September 30 shows a gross profit of \$111,442 from the production of 10,000 tons of ore averaged \$8.94 per ton. The operating cost was \$3.87 per ton. The profit was \$18,147 below the \$129,589 reported for the same period for 1915. The total production for 1916 is 10,000 tons, and the average price received for the ore is \$11.97. The company's production of 10,000 tons is shown in the following table, which will be wiped out one day. No. 1 level, 10 ft. wide, has a short distance to the surface. No. 2 level, 10 ft. wide, has cut in 10 ft. of ore, which is a continuation of the main vein, and is 10 ft. wide. The 700 ft. level. The company's production of 10,000 tons of ore is shown in the following table, which will be wiped out one day. No. 1 level, 10 ft. wide, has a short distance to the surface. No. 2 level, 10 ft. wide, has cut in 10 ft. of ore, which is a continuation of the main vein, and is 10 ft. wide. The 700 ft. level. The company's production of 10,000 tons of ore is shown in the following table, which will be wiped out one day.

Owing to the shortage of 10 ft. wide, and the fact that the company's production of 10,000 tons of ore is shown in the following table, which will be wiped out one day. No. 1 level, 10 ft. wide, has a short distance to the surface. No. 2 level, 10 ft. wide, has cut in 10 ft. of ore, which is a continuation of the main vein, and is 10 ft. wide. The 700 ft. level. The company's production of 10,000 tons of ore is shown in the following table, which will be wiped out one day.

A contract has been let for the construction of a new shaft, drilling on the Thompson mine, which is a continuation of the main vein, and is 10 ft. wide. The 700 ft. level. The company's production of 10,000 tons of ore is shown in the following table, which will be wiped out one day.

The La Roca, which is a continuation of the main vein, and is 10 ft. wide. The 700 ft. level. The company's production of 10,000 tons of ore is shown in the following table, which will be wiped out one day.

high-grade vein, showing free gold. Machinery is being brought in from the old University mine at Cobalt. The same company has taken an option on the Hurd claims, Kirkland Lake.

The Davidson is sinking a new shaft on a vein recently found on its south lot, the ore extracted showing high gold content.

The Cobalt labor situation was summarized in the Press of October 14, so there is no need to cover the same subject again.

The nickel question is being kept well to the front as a political issue in the speeches of leading politicians, and public interest in it has been revived by the attendance of Lord Robert Cecil of the British government, who referred to the *Deutschland* episode as showing the need for greater precautions. The contention of the Hon. J. Howard Ferguson, Ontario Minister of Mines, that the nickel undoubtedly carried by the merchant submarine was not the product of Ontario mines, is not generally regarded as convincing.

SUTTER CREEK, CALIFORNIA

END OF THE STRIKE.—TWO WEEKS' PROGRESS AT THE OLD EUREKA.—SOUTH KEYSTONE, ST. JUNEAU, AND AMADOR STAR OPERATIONS.

The strike of Amador County miners is at an end and the men are returning to work. The evident intention of the Federal Court to prevent the Union's interference with the work, the importation of strike-breakers, and the desire of many of the men to return to work, are the reasons given for disorganization among the strikers. Without waiting for action by the Union, 30 men returned to work at the Bunker Hill mine on October 30. A mass meeting was called for Thursday forenoon at Italian Society park, at which only 150 of the expected 550 men were present. Then it was decided to hold meetings at Sutter Creek and Jackson on the evening of November 2, where the members of each Union voted on the question, "Are you willing to return to work under the conditions submitted by the mine operators?" The following results were made known at 10 o'clock Thursday night. The Jackson Union's vote stood 29 in favor of returning to work and 18 against, which was offset by Sutter Creek Union men voting 48 in favor and 14 against returning to work, the affirmative winning in the two meetings by 15 votes. The reason for the difference in the stands taken by the majority in the respective Unions is that the Kennedy and Argonaut are known to be yielding large dividends, so that the Jackson miners felt they were entitled to more consideration than the Sutter Creek miners cared to demand in view of the fact that Sutter Creek's principal mines have been on an assessment basis for many months and has just levied a 3-cent assessment to raise funds for sinking, and the South Eureka is said to be barely making expenses at the present time. The Kennedy mine, opened on the 3rd with 60 men underground, and the Argonaut, started with 20 miners, a small number compared with their usual crews of 300 and 200 respectively. More men are steadily adding to work, and it is understood that only those who took very active parts in the strike are being refused employment. The South Eureka arranged for the importation of strike-breakers. Richard Carlisle of the Merchant & Manufacturers Protective Association of San Francisco, established a mine on the 1st, 10 more arrived on the 2nd, and a third group on the 3rd. James J. Black, one of the men who had been found dead in bed Thursday morning at a hotel near the South Eureka, but who had been proved that he was a victim of a heart attack, was brought about by over-exertion and

The Kennedy mine usually employs about 100 men, and the Argonaut is shut down for one or two new levels below

3200 ft., the force will probably be increased. At present, that company is offering machine-men, \$3.25 per day; jigger-men, \$3; timber-men, \$3.25; skip-tenders, \$3.25; machine-helpers, \$2.75; carmen and muckers, \$2.75, being the same schedule applying since the voluntary raise of 25c. was made several months before the strike occurred.

At the Bunker Hill and Keystone mines in Amador City, the owners have made use of the cessation of the usual mining and milling operations to make extensive repairs to their surface plants, as well as in the shafts; the Argonaut company has gone ahead with its mill and tramway system during the strike; and the Kennedy has installed new boilers and enlarged its tailing dam, so the time has not been lost.

Despite encountering numerous caves in the shaft, and the necessity of straightening out a bend near the 800-ft. level, there has been fair progress made during the week in unwatering and re-timbering the Old Eureka shaft, the water now being down to a point about 850 ft. from the surface. The pumping system is working well, and by removing the hump or bend caused by too closely following the vein when this shaft was sunk, considerable inconvenience and expensive up-keep will be avoided in future operations. About half of the crew of 50 men is engaged in surface construction and preparations for the installation of the large hoist and steel head-frame. It is understood that H. L. Gooding, the head mechanic at this property, has resigned to accept a position in Colorado.

The old Eureka shaft has been unwatered and re-timbered to a depth of 830 ft., and far less difficulty is being experienced in clearing the shaft below the 800-ft. than was anticipated. The new 9000-gal. tank at the 500-ft. station has been completed, including the concrete work on that large reservoir. The pumps so far connected up are throwing a good stream, and good speed can now be made in re-opening this old producer. On the surface, the work of installing the heavy hoisting machinery is proceeding steadily. Men are now putting in the foundation forms for the hoist and working on the steel head-frame, which will soon replace the low wooden structure now in use. About 50 men are steadily employed.

The fine new electric hoist at the Plymouth mine has been in operation for a little over a week and is giving excellent satisfaction. This is the largest hoist in Amador county.

There appears to be some prospect of the early resumption of work at the old St. Jeanne mine near Jackson. A. Caminetti, Jr., has been on the ground during the week with James Ferrari estimating cost of machinery and supplies necessary for its re-opening; and it is also reported that T. M. Woode and J. S. Rear, Vancouver mining men, who are interested in Calaveras County mines, are considering the purchase of this old mine. The St. Jeanne is a pocket mine, one of which a number of years ago is said to have yielded \$75,000. This property, four miles south of Jackson, is on the "black metal" belt to the west of the Mother Lode, and samples recently taken show the slate in the formation to be full of gold-bearing sulphide. There is an adit 1000 ft. long in the ground.

Surveyors have been at work recently on the old Mitchell mine near Middle Bar, and it is also reported that the Mammoth tunnel, or Neville's mine will shortly be re-opened by a son of the elder Neville's former partner, Senator Jones.

As many men as can be worked to advantage are now engaged in unwatering and re-timbering the Hardenburg shaft near the Mokelumne river. This property was recently taken over by W. J. Lorine and others.

During the week, the sale of the briquetting plant of the Lignite Fuel Co. of Ione to C. A. Johnson has been concluded, for \$19,500. Borings and shafts show that nearly all of the valley between Ione and Carbondale is underlain by lignite strata, and with new capital for more extensive development, success seems certain for this industry.

Shaft-sinking and development are progressing most satisfactorily at the Amador Star, better known as the Rhetta

mine, four miles north of Plymouth, where Baylies C. Clark of Sutter Creek has a small crew employed. This mine was formerly worked by an adit, and when the new owners decided to sink a shaft 200 ft. south of the adit, they had to sink only 227 ft. to strike a body of ore 4 ft. wide, which assays well. Drilling is now in progress on this ore. The mine is electrically equipped and well situated for economical mining.

Work was commenced during the past week at the South Keystone property, near Amador City, and preparations are well under way for installing the machinery purchased on October 19 from W. J. McGee, assistant U. S. treasurer. McGee has sold to the new company the hoisting plant used a number of years ago at the Amador Queen property, two miles south of Jackson, and men are now engaged in preparing the engine, compressor, etc., for removal, while others are getting foundations ready for same at the North Star shaft of the South Keystone Consolidation. The group includes the McIntire, South Keystone, North Star, and Boyson claims, and lies near what is known as the "Amador Trail" between Sutter Creek and Amador City. Through the strenuous efforts of John A. McIntire, of Sacramento, negotiations were practically closed on this mining project last May, but unexpected delays occurred. Anton Huth, the Tacoma capitalist, with other Washington men was heavily interested in the project. Since his death in September, his interest has been taken over by his son, and a corporation was formed, capitalized at \$1,000,000, in shares of \$1 each, with the following officers and directors: W. Virges, president; C. H. Colpe, vice-president; Frank F. Wood, secretary and treasurer; John A. McIntire, director; and Carlton Huth, director. Colpe will act as general manager for the company, and he has employed J. Gallagher of Calaveras county as foreman. With the exception of John A. McIntire, all the directors are Tacoma men, although Wood has resided in San Francisco for the past two years. McIntire was the owner of the McIntire claim and also interested heavily in the South Keystone, and his faith in the property is shown by his retaining a substantial interest in the company as now incorporated. The first work contemplated is the unwatering and re-timbering of the North Star shaft, which has a depth of 1000 ft. From the 600-ft. level of this shaft, drifts will be driven to tap the orebodies in the South Keystone and adjoining claims. Indications are excellent for the development of large reserves of high-grade ore in this property in return for a comparatively small amount of work. Having as neighbors such well known old producers as the Keystone and the South Spring Hill mines, and having indications favorable for fully as good results as have been obtained at the other great mines of the county, this stretch of mining ground is locally held in high esteem and considerable interest is manifested in this new venture.

A heavy truck has been in use all the week hauling the machinery and entire surface equipment from the Amador Queen mine, south of Jackson, to the South Keystone mine, now about to be opened near Amador City. The hoist and other machinery will be put into service at once at the North Star shaft, from which the consolidated claims are to be developed. C. H. Colpe, the manager, is here assisting the foreman, J. Gallagher, who has a small force at work installing machinery. A drift will be run north from the North Star shaft into the South Keystone.

PROCEEDINGS of the Mine Inspectors' Institute of America covers 115 pages. The annual meeting was held at Joplin, Missouri, on June 13-15, 1916. Thomas Graham of Victoria, B. C., is president; the secretary is J. W. Paul of Pittsburg, Pa. Papers were read on gaseous coal mines, the lead-zinc mines of Joplin, mine inspection and safety first in California, permissible explosives, mine inspection in British Columbia, efficiency in mine inspection, and underground haulage. The next meeting is to be held at Indianapolis in July 1917.

SONORA. To work the old Confidence mine the Confidence Gold Mines Corporation has been formed with a capital of \$600,000. Past development is to a depth of 1110 feet.

YOU BET. Dredging is to be started by Los Angeles people at the Greenhorn at an early date.

COLORADO

On January 3, 4, and 5 the Colorado Metal Mining Association will hold its annual meeting at Denver. The proposed repeal of the present law for taxation of producing mines, proposed regulation of smelters by the Public Utilities Commission, tariff laws, and proposed new Federal mining law are subjects to be discussed. The tungsten miners are also preparing for the meeting.

BOULDER. To treat independent miners' ore the Degge-Clark company has erected a mill $5\frac{1}{2}$ miles from this centre. Low-grade tungsten ore is purchased.

BRECKENRIDGE. Profits of the Tonopah Placers Co. in the quarter ended August 31 amounted to \$54,780, against \$39,454 in the previous period.

CRIPPLE CREEK. Two carloads of ore from the Cresson mine sent to the Golden Cycle mill yielded \$200,000 net. This ore was from No. 15 level, where a large shoot has been opened for 150 ft. in height. Numerous vugs were found, some containing rich specimens of calaverite.

The first shipment of flotation concentrate from the Vindicator Consolidated's new mill has been made.

The Mary McKinney company paid 1c. per share last week. The shaft is now 1360 ft. deep. Prospects generally are good, although No. 11 level was disappointing. From January 1 to September 30, 1916, the revenue totaled \$193,859, of which

\$118,524 was from company and \$71,256 from lessees' ore. The profit was \$10,333. The cash balance is \$98,535.
